The Dakota formation at Ouray (27) is called 'the upper quartzite', it consists there of hard sandstone separated into two or three beds by thin bands of shale. It is about 150 ft. thick and forms bold cliffs. In this formation are found several curious ore deposits.

The gold deposits in the granite-gneiss of the Plomo district, in Costilla county, and on the western slope of the Sangre de Cristo range are in an Archean, or at least Algonkian, formation. The ore occurs in zones of crushed rock near lines of faulting.

The three terrains most productive of gold and silver in Colorado have proved to be the Tertiary volcanic rocks, the Carboniferous limestone, and the Archean granite-gneiss. The last of these was the first to be prospected because it constitutes a large part of the Front range of the Rocky mountains where they rise abruptly above the plains over which the pioneers came westward. The mines of Boulder, Gilpin, and Clear Creek counties are mainly in the granitoid gneiss, some of which may be Algonkian and represent metamorphosed sedimentary rocks. In this basal complex are found dikes and other less regular intrusions of andesite and felsite the age of which it is not possible to state with certainty because they do not traverse any of the later sedimentary strata; but by their resemblance to the eruptive rocks of neighboring districts it is presumed that they also were intruded during early Tertiary time. This much can be said: all the lodes containing gold and silver as yet discovered in Colorado are associated, directly or indirectly, with intrusive igneous rocks the age of which when ascertainable is found to be post-Cretaceous. This points to an era of intense thermal activity supervening upon the volcanic disturbances for which the early Tertiary period is remarkable in Colorado.

The study of the orographic features of Rocky Mountain geology has demonstrated several facts of great significance. For the ascertainment of these facts we are indebted in large measure to the investigations of R. C. Hills, a geologist long resident in Colorado as a specialist on the stratigraphy of the coal measures. In his address as president of the Colorado Scientific Society, in 1888, he established several points of prime importance. Thus, he showed that "the tilting and overturning of strata observed along the mountain border, both east and west of the continental divide, are due to a general movement affecting all the Eocene sediments, except the Uinta group" and that "the more salient features of the orography [of this region] were created in post-Cretaceous time." The great faults traversing the Rocky Mountain uplift involve Cretaceous beds, and are therefore of Tertiary age. The early Eocene was marked by a succession of stupendous eruptions, covering an enormous area with lava and breccia to a depth reaching in places to several thousand feet, especially in the counties of San Juan, Hinsdale, Ouray, San Miguel, and Rio Grande—forming the larger part of what is now called the San Juan region, after the name of the river into which its drainage is discharged. Subsequent regional movement of great intensity, and accompanied by extensive flexures, culminated in faulting that left dislocations measured by 5000 to 8000 ft. All of the districts now the scene of mining in Colorado were affected. The upper channels of the principal rivers were established during this period. Then followed another series of eruptions, extending into the Miocene, "amplifying the effects of simple orogenic movements." Mr. Hills also says: "In the Rocky Mountains of New Mexico, Colorado, and Wyoming, all the eruptive bodies belong to a time not earlier than the close of the Cretaceous, and the majority to a time subsequent to the close of the Eocene." He refers to possible exceptions, but concludes that "no important outbursts of eruptive material took place previous to the Tertiary." Some of these eruptions were contemporaneous with the great fault-movement, others followed. "The injection of sheets of lava into strata previously flexed" was a noteworthy structural feature of the region. Late in the Pliocene and again in the post-Pliocene period renewed movement caused faulting and folding, accompanied by eruptions of restricted character, especially southward into New Mexico. Thus the broad fact is emphasized that the Cenozoic was the mountain-building era in the south-central Rocky Mountains and that the Tertiary eruptions augmented and modified the previous orographic features.

To these grand geological events the formation of ore deposits is related as one of the minor consequences of wide-spread and intense thermal activity. At the close of the series of volcanic eruptions, the smothered plutonic energy found vent in the form of geysers and hot springs. Heated water circulated along the fractures and fissures, which were formed in the first place by excessive strains and subsequently by the cooling and shrinking of the extravasated igneous material. This heated water carried metals in solution, the source of such dissolved metals varying according to the origin of the water. Descending meteoric waters carried entrained oxygen below the surface, and magmatic waters representing the last phase of differentiation brought sulphides from the deep where slumbered the subterranean fires. In the approach to surface, and particularly at that horizon known as the water-zone, the precious metals were precipitated, forming the minerals for which the miner searches with labor unceasing and hope unabated.

The Bayhay Valley Oil Co. has recently been organized at Manila for the purpose of sinking wells on 11 claims in the Tayabas oil district on the Island of Luzon. The total area comprised in the claims amounts to about 200 acres. They are situated on the Bayhay river, three miles from Ragay gulf, and it is intended when the wells begin to flow to put in an 8-in. gravity pipe-line from this property to tidewater. A wagon-road is now nearing completion from the gulf to the Alabama claim in the group. There is a test well 120 ft. deep, with a 5-in. bore, now on the Alabama claim. The well can be pumped perfectly dry and the oil will seep in at the rate of from one to three barrels per day. Two wells are to be drilled at once.—*Philippine Resources.*

Platey Jointing in Breccia at Cripple Creek.

Cyanidation of Silver Ores.

Written for the MINING AND SCIENTIFIC PRESS
By LLOYD B. KNIFFIN.

In striking contrast to the usual method of cyaniding Mexican silver ores is the treatment which we have been using at the Zambona mine in the Alamos district of Sonora, Mexico. The unusual feature is the extreme rapidity of solution of part of the silver in cyanide, and the peculiar advantage of concentrating before cyaniding. The ore consists principally of orthoclase feldspar, very much brecciated and filled with calcite. Distributed throughout the ore is the sulphide of silver, argentite, in all sizes down to minute particles. This mineral was formerly the chief object of mining in this camp, when transportation was expensive, and it sometimes occurred in pockets of considerable size. The silver sulphide is easily removed by concentration on Wilfley tables, and in this way an extraction of 50% of the total silver is obtained. For several years this method has been used, and the tailing stored. At present the mill is engaged in grinding and treating this ore with cyanide.

The process is as follows: Cyanide solution (0.075% free KCN) is mixed with the ore in the ratio of 6 to 1, and the sand separated and discharged to tube-mills by Dorr classifiers. The discharge from the tube-mills is returned to the classifiers, and the overflow from these goes to Dorr slime-thickeners. The underflow, at a ratio of 1½ to 1, is stored for delivering to the filter-presses as needed. Thus, concentration and grinding in solution, without agitation of any kind, is all the treatment required to reduce a 16-oz. ore to 1.3-oz. silver per ton.

The ore is also remarkable on account of its sensibility to low strengths of cyanide. The following table shows the results obtained with a free cyanide strength of 0.042%; the total cyanide was 0.066%, and the protective alkali, 0.046% CaO.

	Silver, oz.
Ore after concentration in water	8.30
After mixing with solution	4.48
Sand from above (tube-mill heads)	5.52
Tube-mill tailing, 52%, coarser than 200 mesh	5.28
Discharge from Dorr thickener	2.72
After standing six hours pulp was pumped to Pachuca tank without addition of cyanide	2.28
After 6 hr. agitation	2.18
After 9 hr. agitation	1.96
After 18 hr. agitation	1.82

The tailing consisted of 42% slime, assaying 1.44 oz. Ag; 45% sand finer than 200 mesh, with 2.06 oz. Ag; 13% sand coarser than 200 mesh, assaying 2.42 oz. Ag. It will be seen that both in time of treatment and in strength of cyanide necessary, this ore is similar to ores containing embolite and native silver as described by Theo. P. Holt, in the MINING AND SCIENTIFIC PRESS, July 31, 1909. In order to check this theory, as to the form of combination of the silver, the following test was made on the suggestion of E. M. Hamilton. To the working solution nitric acid was added in excess and the mixture boiled. The resulting precipitate (silver cyanide and chloride) was removed and treated with hot concentrated nitric acid. The precipitate which was then insoluble was easily dissolved in ammonia. This established the presence of chlorides in the solution, and probably therefore in the ore, although the water used for washing on the slime-filter press contained traces of chlorides. Whether the ore also contains native silver has not been proved.

For a short time the mill and cyanide plant were operated without concentrating, and in order to effect the same extraction as obtained with combined concentration and cyanide treatment it was necessary to use a 0.15% free cyanide solution and a 30-hour treatment in Pachuca tanks. In this case it was necessary to dissolve the argentite, which in general was separated as concentrate, as well as the chloride, which yields to shorter treatment.

It has proved here, as at Copala (MINING AND SCIENTIFIC PRESS, June 8, 1907, p. 719) that a high protective alkalinity is necessary with this ore in order to keep down the quantity of zinc in solution; and that even with the protective alkalinity constant at 0.1% CaO it is only safe to regulate the solutions by the free cyanide test, because the variations in zinc and copper present often cause the indicated total cyanide to vary from an amount less than the free cyanide present to three times the free-cyanide strength. Under this latter condition the recourse is to increase the protective alkalinity to 0.15% CaO, and then the zinc goes down to the normal quantity; but on account of using vacuum-filter presses, with a canvas filtering medium, it is not expedient to keep the slime permanently at this high strength.

Although it is usually stated that the zinc is precipitated from working solutions as cyanide of zinc, it seems probable here that basic zinc carbonate, at least under some conditions, is thrown down. The reaction ought to regenerate free cyanide, and this is usually observed to be the case, for the cyanide rises as the zinc decreases.

Topographic maps named below were issued by the United States Geological Survey during September, October, November, and December 1909: Alaska, Fairbanks (price 25c.); California, Carbondale, Clay, and Florin; Idaho, Garden Valley; Illinois, West Frankfort; Kentucky, Central City, Earlington, Madisonville, and Providence; Minnesota, Rockford; Montana, Sapphire; New Mexico, Gallina; New York, Watertown;* Ohio, Continental, Lancaster, Lisbon, Logan, and Newark; Oklahoma, Luther, McAlester,* Tuskahoma,* and Winding Stair;* Pennsylvania, Bellefonte; Tennessee, Franklin; Wisconsin, Sparta. Maps marked with an asterisk (*) are new editions of old maps. The price of these maps (except as noted) is 5c. each, or $3 per hundred if that many or more are ordered. Payments should be made by certified check or by postal or express money order, payable to the Director, U. S. Geological Survey, or in cash—the exact amount.

Alaska was bought from Russia in 1867 for $7,000,000. Its gold output since 1880, when placer mining began, amounts now to $161,000,000, and the exploitation of its resources of copper, coal, and other minerals has hardly begun.

Philippine Coal Mines.

The East Batan coal mine is located on the southeastern end of the Island of Batan, Province of Albay, Philippine Islands. The claims were originally located in 1903, but no effort was made toward developing the property until 1906. During the month of October of that year, active operations were commenced, in a small way, on a 3-ft. seam lying to the east of the village of Batan, and by the end of December, the same year, 200 ft. of entry had been driven and about 150 tons of coal taken out and stored. A light wharf was completed and a small portable track laid from the mine out to the end of the wharf where lighters could be loaded. The half-ton cars were moved by hand. Occasional sales of a few tons of coal were made from time to time to launches passing near the mines; but it was not until March 2, 1907, that the first steamer was coaled there. On that date the *San Juan*, an inter-island steamer, took on board 75 tons. The coal gave satisfactory results. Development work was steadily continued, and from time to time other steamers began to call at Batan for coal. During this period all work had been done by private capital. In September 1907 it was found that additional capital would be required to purchase the machinery and equipment necessary to continue the development work on a more extensive scale. This resulted in the organization of the East Batan Coal Company.

In November, work was commenced on the 5½-ft. bed, lying west of the village and worked on the 3-ft. seam stopped, it having proved more profitable to work the larger seam. Since July 1908 a more vigorous policy of development has been pursued through the aid of additional capital. Among the improvements made may be mentioned the building of more lighters to expedite the coaling of ships; a wharf 300 ft. long with sufficient water to accommodate the largest ship in the world; a railroad from the mine to the wharf with an equipment consisting of two locomotives and 50 two-ton cars, thus making it possible to deliver coal direct from the mine to the ship, avoiding the costly re-handling of the coal; a steam launch to aid in the harbor work and place the mines in communication with outside ports. New streets also were laid out in the Barrio, and it now represents a clean healthy little mining camp of 2000 souls. During all this period of outside improvement the work below ground had not been neglected, but a greater force had been employed, and with the additional equipment gratifying progress had been made in driving tunnels and galleries, until at present the work below ground aggregates several miles.

The coal removed during development has all been consumed by coasting steamers, and the funds derived from the sale have been applied to the work, until now nearly a half million tons is blocked. The coal-seam shows no rolls or faults.

The bulk of the mining and all outside work is done by Filipino labor, which has proved entirely satisfactory, and of which there is an abundant supply. Several experienced Japanese miners and timber men are also employed in timbering and special development work. There has been no labor trouble of any kind and no trouble has been experienced in procuring all the men needed. Experience at these mines during the past three years has shown that the Filipino takes readily to mining, and, under competent supervision, has proved as reliable and satisfactory as any labor found in the Orient. The entrance to the harbor at Batan is well marked with concrete beacons, built by the Insular Government; and range lights have been established for the convenience of ships desiring to enter or leave the harbor at night. There is an average of 54 ft. of water, with mud bottom, making excellent holding ground.

It is proposed to make Batan the quickest cargo-handling port in the Far East, which can readily be done by taking advantage of the mine and harbor's natural conditions. The pit-mouth is within 600 ft. of the sea and within 3000 ft. of the wharf, where the largest ships in the world can load at all times and seasons. Under the proposed new method, the coal will be touched by hand only once, and that is when it is shoveled into the trucks down in the mine, and it goes from there direct to the ship's hold or bunkers, being loaded into the ship mechanically.

It is proposed to install a complete electric plant at the mines, using electrical coal-cutting machines, electrical coal-gathering equipment, and electric pumps, and to light the mine throughout by electricity. This new system will be used to light the plant outside the mine, and will make it possible to despatch ships either night or day. It is proposed to extend the present wharf from 300 to 600 ft. and increase the present bunkers now in course of construction to a capacity of 6000 tons. Under this method ships can load with bunker coal in a few hours, while a cargo ship could be loaded with 6000 tons within 24 hours at a cost of a few cents per ton.

Coal to the amount of 494,209 tons, with a market value of about ₱5,000,000, was imported into the Philippine Islands during the past fiscal year. With the proposed new equipment the greater part of this coal can be supplied from the mines of the East Batan Coal Mining Co., and the millions of pesos paid for the same thus be kept in the Philippine Islands, instead of going out of the country, as at present. The commercial value of Batan coal is shown by the report of the Philippine Bureau of Science, recently published, giving the results of a practical test of Australian *versus* Batan coal as used on two Government coast guard vessels, sister ships, having the same equipment throughout. The test as given is by ordinary steaming for a distance of 5000 miles. The cost to the vessel using Australian coal was ₱0.66 per mile, and to the vessel using Batan coal ₱0.38 per mile, ₱1500 being saved by using Batan coal on a 5000-mile run.

In 1903 the United States Government commenced prospecting for coal on the west end of Batan island, some ten miles distant from the East Batan mines. The results were so satisfactory that, in 1906, the west half of Batan island was declared a military reservation. Diamond-drill work and mining have been steadily continued, and about ₱700,000 have been expended since operations were commenced in 1903.

Stability of Dams.

By J. F. Jackson.

*In the old-fashioned timber dams, hundreds of which have been built for logging and power purposes, on all sorts of foundations, it was customary to give the water-tight surface of dams a slope upstream generally two or more horizontal to one vertical, making a cross section something like Fig. 1 in the case of an overfall dam. For the purpose of a coffer-dam of moderate height on solid rock or impervious bottom, the same general idea is satisfactory, as shown in Fig. 2. In this diagram the planking is shown laid at slope of one to two. Note the position and direction of the resultant of water pressure. Little theoretical study, as far as I know, has been given to these forms of dams. It is obvious

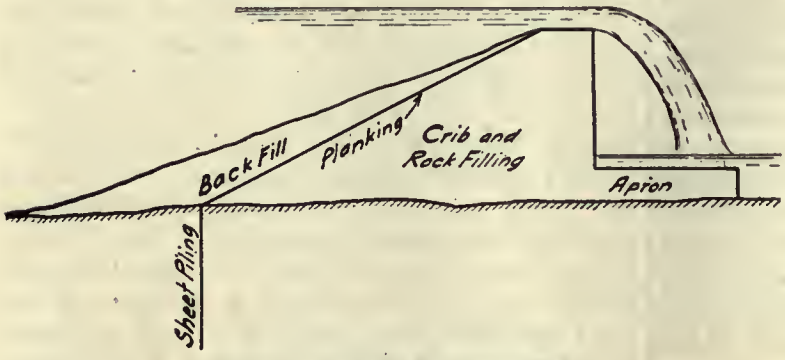

Fig. 1. Cross-Section of Timber Dam.

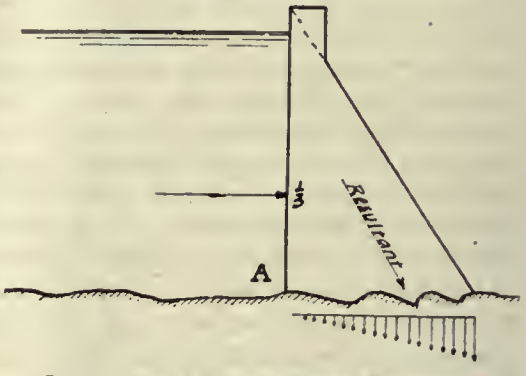

Fig. 3. Typical Cross-Section of Masonry Dam.

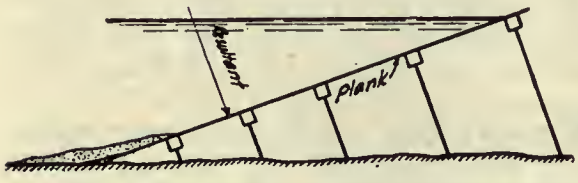

Fig. 2. Cross-Section of Coffer Dam for Shallow Water.

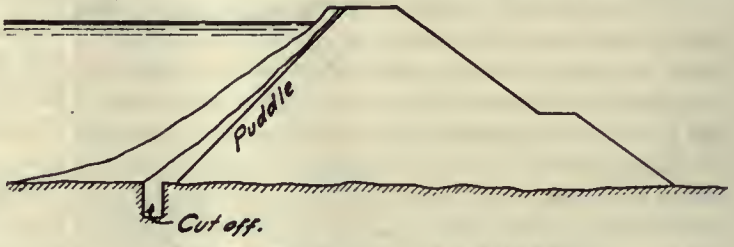

Fig. 4. Typical Cross-Section of Earth Dam.

in each of the above cases that the weight of the water and the back filling have been a large or the entire factor in the stability of the dam, both against sliding and overturning. The beaver has always utilized the weight of water for stability, and some of his achievements have been truly remarkable. The lower part of beaver dam is always open for drainage. His work is more scientific than that of some of our modern builders.

The first masonry dams were probably built entirely by guess, but some of them stood. A precedent having been established, in course of time mathematicians came along and found that masonry structures having a factor of safety of two against overturning and of one against sliding on their bases were actually standing up. Therefore, a coefficient of friction of 0.6 or 0.7 was assumed, and a sufficient weight of masonry provided to resist the horizontal hydrostatic pressure of the reservoir. Hence we have the standard triangular or trapezoidal section as shown in Fig. 3, in which the resultant pressure of water and masonry usually falls just inside or at the middle third of the base, so that pressure begins practically at zero at the inner heel and increases to a maximum at the outer toe, as illustrated below, provided the structure acts as a unit. The pressure of water and weight of masonry are such that the coefficient of friction is barely sufficient to resist sliding. In fact, if it were not for the dove-tailing into rock at the base of the dam and into the walls of the gorge between which the dams are built, there would be many more failures by sliding than there have been. However, so far as mathematics are concerned, we have the astonishing fact that in masonry structures of immense importance, and in perhaps no other cases, engineers are content to follow in the rut and build with a factor of safety of one. Further than this, as soon as you assume hydrostatic uplift, or that water enters under the edge *A* of your dam, your precious friction coefficient is partly destroyed, and the dam fails. It is only fair to say that most engineers now make some attempt to drain toward the downstream toe of the dam. The form of masonry dam is somewhat circumscribed by the fact that no tension is assumed on the upstream face. I nevertheless believe it quite possible to develop a form of masonry dam in which the weight of water and possible backfill is utilized to add stability. The ordinarily accepted coefficient of friction as indicated above and the factor of safety of two against overturning, should not be accepted as sufficient. In earth dams, I believe that the section should be something like that shown in Fig. 4.

The same idea applies to an earth dam, a rock fill dam or like structure with a cut-off planking, reinforced concrete, steel plate, or common puddle. In every case water-tightness should, if possible, be secured as near the water itself as possible, and the vertical components of the hydrostatic pressure should be equal to or exceed the horizontal ones. Western engineers have already followed this idea to some extent in earth and in rock fill dams with planking. Designers of concrete dams have usually followed the standard masonry profile or something like it. Happily, Bainbridge with his steel dam, and

*Abstract from *Jour.* West. Soc. Eng., Vol. 14, No. 5.

Ambursen with his concrete dam, and the idea of the reinforced concrete retaining wall came along, so that it is now in order to consider a dam having a water-tight face capable of taking tension. Bainbridge's dam consists of a series of inclined bents covered on the upstream side with water-tight concave plates. In this dam, water pressure is taken normal to the water-tight face. The column loads are taken directly to the rock bottom, and tension of face plates is taken up by anchor rods.

If it be not founded on rock, the design must be altered radically, as indicated further on. Although

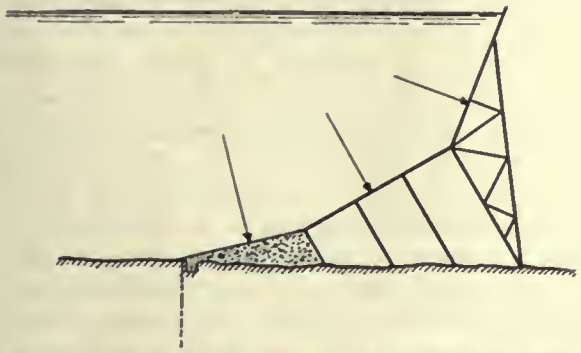

Fig. 5. Cross-Section of Suggested Concrete and Steel Dam.

the Ambursen dam utilizes the weight of water to some extent, in my opinion it does not, as ordinarily constructed, provide much greater stability against sliding than the standard profile, though it does thoroughly provide against hydrostatic uplift by the open construction of its base. The main idea of Ambursen's patent was apparently to so construct the water face of his dam with reference to the cross-walls that the direction of water pressure at any point should fall within the base. The calculation of stability of a steel dam on rock bottom, with given factors of safety, is much simpler and more certain

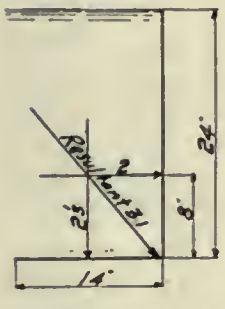

Fig. 6.

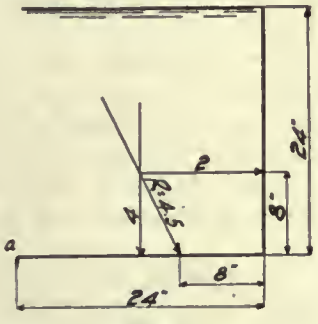

Fig. 7.

Cross-Sections Showing by Bent Plates the Principles Suggested.

than even the design of a steel railroad bridge, and I believe that the time is coming when the merits of this construction will be much more appreciated by engineers than at present.

In designing the cross-section of a steel dam about 100 ft. high, I accidentally hit on the idea of making the part near the top, where hydrostatic pressures are light, nearly vertical, and sloping the part near the bottom, where hydrostatic pressures are heavy, until it was nearly horizontal. This resulted in a saving in construction cost, and a greatly increased factor of safety against sliding and overturning. The idea is illustrated in Fig. 5, where the plating on the lower section is supported directly in concrete, cheap masonry, or other filling, while the upper part is of steel construction. The amount, position, and direction of resultant pressures depend upon the exact shape of the water-tight surface. The vertical water pressure may be made 1.5, 2, or even 3 times the horizontal pressure, depending on the width of base; and the resultant pressure of all, weight of water and structure, may be brought as near the centre as desired. The limits of this idea are shown in Fig. 6. Suppose we have a dam built of a small bent plate; calling the height 24 in., the base 14 in., the horizontal water pressure would be 2, applied at 8 in. from the base; the vertical pressure would be 2.33, applied at 7 in. from the bend. The resultant would be 3.1, applied practically at the bend. The structure would be just a little more than stable against overturning, and a friction coefficient of 0.86 would be sufficient to prevent its sliding. In case the base were 24 in. and the height 24 in., as in Fig. 7, the horizontal water pressure would be 2 as before, and the vertical pressure would be 4, and

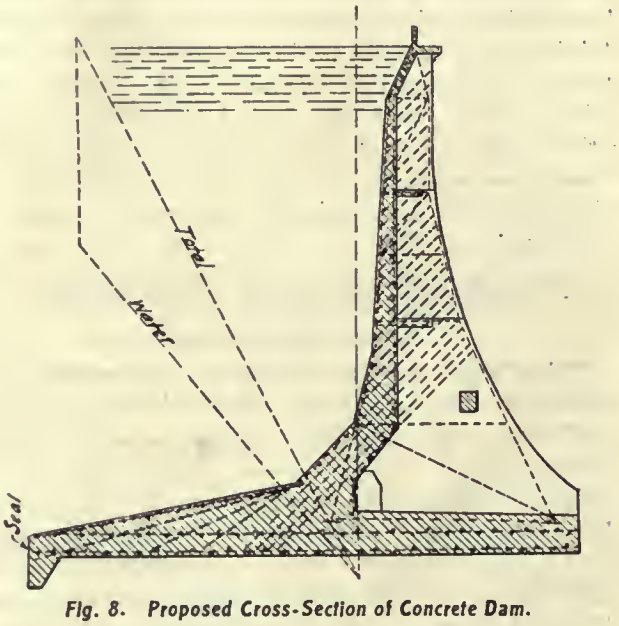

Fig. 8. Proposed Cross-Section of Concrete Dam.

the resultant 4.5, falling at a point one-third of the distance from the bend to the upstream edge of the horizontal plate. This resultant would stand two vertical to one horizontal, giving a coefficient of 0.50 to just prevent sliding. If leakage at *A* be prevented and the plate be stiff enough to preclude bending, there will result, due to water pressure alone, a small dam as safe against overturning and safer against sliding than the standard profile. It is evident, then, that in a dam having a base equal to its height, the sum of all horizontal pressures is exactly that due to the depth of the water, no matter what the shape of the water-tight surface, and it is possible to utilize the vertical pressures from a minimum of zero to a maximum of two times the sum of the horizontal forces, and to bring the resultant of both forces from a horizontal direction to an inclination of two vertical to one horizontal, as shown. Of course, in the practical structure of steel of the Bainbridge type or of concrete, wood, or other material, the tension face would be curved in some manner, and in making calculations the weight of the structure itself should be added.

In Fig. 8 is shown the proposed section of a reinforced concrete dam having a concave water-tight

face. Note the position and direction of the resultant of the water pressure and also note that the total resultant falls about half way between the centre and the ⅓ point. It is designed to be a heavy and substantial structure, but contains only about one-half the amount of concrete of that required in a dam of standard cross-section. In this particular case the water pressure resultant stands at an angle of five vertical to four horizontal, and the total resultant at eleven vertical to five horizontal, and the structure evidently has some stability against both overturning and sliding. A spillway section employing this principle also works out favorably in either steel or concrete. The Patent Office has recently recognized this principle of using hydrostatic pressure on a concave face to add stability to dams. So far as I know, this is the first recorded recognition of the hydrostatic principle involved. I do know, however, of a mining engineer out West who once built a small concrete dam wrong side to, and with good results. The modern inside buttressed reinforced concrete retaining wall employs a similar idea, but the earth pressures are not hydrostatic. In the earthen dam with masonry core-wall, the hydrostatic pressure against the core is greatly modified, though nobody knows how much, by the presence of the earth-fill on the water-side. Its design is eminently a matter of guess work.

STANDARDIZATION OF EXPLOSIVES.

By Charles E. Munroe.

*That some definite standard of composition is needed for explosives offered on the market may perhaps be made apparent by instancing dynamite. As invented by Nobel it consisted of an absorbent, called a dope, and nitroglycerin. The absorbent long used commercially was kieselguhr. It was made to absorb and hold various percentages of nitroglycerin up to 75% of the dynamite produced, and the product was styled by a name such as 75% dynamite, which indicated the quantity of nitroglycerin contained in it. Kieselguhr is incombustible, so it and substances like it that were used as absorbents were called inexplosive dopes. Nobel also found, however, that gunpowder or gunpowder-like mixtures, such as wood-pulp and nitrate of soda, would act as satisfactory absorbents for nitroglycerin, and hence a large number of dynamites have been made and used with these explosive dopes, but since there has been a dispute as to any useful explosive effect from the dope, these dynamites have been generally rated by their nitroglycerin content only. Later it was discovered that explosives such as the cellulose nitrates, which, like nitroglycerin, can be made to detonate, could form compositions with nitroglycerin, and such compositions, or others with nitro-substitution compounds mixed with a dope, have been offered in the market as 40 or 60 or other per cent dynamites, though they contain less than the designated percentage of nitroglycerin. It is claimed by the manufacturer that the new compositions are as strong as a straight dynamite containing the designated percentage of nitroglycerin. This may be true for a certain set of conditions; in fact, the new composition may be under certain circumstances not only as efficient as the straight dynamite, but even more efficient. Nevertheless the consumer is entitled to know definitely by some conventional means the nature and composition of an explosive which is publicly offered for sale, in order that he may decide for himself when and how he shall use it and what is a reasonable price to pay for it.

As another example may be cited black blasting powder, which, as invented in 1857 by La Motte DuPont, is a mixture of charcoal, nitrate of soda, and brimstone. This has been extensively used in mining in this country, particularly in coal mining, so that at the census of 1905 the production amounted to 205,436,180 lb.; yet today no standard exists as to the kind of wood from which the charcoal is to be made, the manner in which and the degree to which it is to be 'burned', the proportions in which the components of the powder are to be mixed, the conditions and extent of incorporation, or the quantity of moisture which may be left in the finished grains. Neither have any steps been taken until recently to insure uniformity in granulation, although this feature is of vital importance and its effect well known.

As a third example, the classification of detonators, known also as blasting caps, may be mentioned. These powerful and delicate initial sources of detonation have been graded by a variety of methods at the will of the manufacturer, whereas the vital information which the consumer should possess is a knowledge of the quantity of fulminating composition contained in each capsule. The system of grading should therefore be so conventionalized as to set this forth explicitly.

The mine inspectors in several States have taken up the inquiry and it has been experimentally examined by the Technologic Branch of the United States Geological Survey at the Pittsburg Testing Station. The Bureau of Explosives of the American Railway Association has also been making investigations into the composition of commercial explosives, particularly as it affects safety in transportation. But a still broader field for standardization exists.

*Abstract from *Proceedings* of the Amer. Soc. for Testing Materials.

The average consumption of fuel per brake-horse-power hour in gas-producer tests made by the United States Geological Survey was 1.36 lb. of bituminous coal, or 1.99 of lignitic coal, the minimum consumption being 0.84 and 1.48 lb., respectively. Comparative tests of 75 bituminous coals under a water-tube boiler and in the gas producer showed that the average fuel consumption per brake-horse-power in the steam-plant was 2.7 times that in the producer plant. Several low-grade coals and lignites that were of little value, or even worthless, under the steam-boiler gave excellent results in the producer.

Nevada has recently been re-studied in a reconnaissance of mining camps in Elko, Lander, and Eureka counties, by W. H. Emmons, of the United States Geological Survey, whose report is just printed as the Survey's Bulletin 408. The region covered, comprising 7000 square miles, has produced silver and gold worth about $50,000,000.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Australian Gold Production.

The Editor:

Sir—In 'Ridpath's Universal History', Volume VIII, page 860, I find the following statement: "The industrial development of Australia may be further illustrated with a few additional facts gathered from the census of 1881-82. At that time the total aggregate of gold taken from the mines of Victoria had reached the enormous sum of a thousand and ten billions of dollars. The aggregate from New South Wales was a hundred and seventy-two billions, and that from Queensland fifty-six billions, which, together with the yield from Tasmania, made a grand total of a thousand two hundred and fifty-five billions of dollars." Is it true that the Australian census reports contain such absurd statements, or did Mr. Ridpath get his ideas as badly confused here as he did in many other places throughout his work?

J. W. BUSH.

Lower Lake, California, February 9.

[We do not have a copy of the census report at hand; perhaps some of our readers can answer the question. Probably the error was in the History rather than the Census.—EDITOR.]

Geology at Globe, Arizona.

The Editor:

Sir—"In 1903 was published the first report by the United States Geological Survey on one of the Southwestern copper districts, based on field work done in 1901 and 1902." The above is quoted from the first sentence of a contribution by F. L. Ransome under the same caption that heads this article, and the report referred to is of course Mr. Ransome's work on the Globe quadrangle. In this last article, which appeared in the MINING AND SCIENTIFIC PRESS on February 12, 1910, Mr. Ransome has for the first time to my knowledge corrected certain serious mistakes in the above-mentioned report. Mr. Ransome continues as follows: "At that time practically nothing was known of the geologic relations of the copper ores of Bisbee, Clifton, and Morenci, Ely, Bingham, and Yerington." Possibly some of us who had the pleasure of examining some of the Southwestern copper camps before the publication of the reports of the United States Geological Survey were not in quite such dense ignorance in regard to what we saw as Mr. Ransome would have us believe, and we were able to gain some notion as to the structural relations of the deposits. But few, however, will hesitate in giving the Survey credit for the way it has taken advantage of its opportunities for geological field-work, which until recently were not allowed to the consulting geologist, and the reports mentioned have, more than all other literature combined, contributed to the knowledge of copper deposition.

With the advantages of the United States Geological Survey organization behind him, the Government geologist is expected to do excellent work. The specialist, examining an individual deposit in a region mapped by the Survey, should be able to have confidence that the general work of the Survey forms a reliable basis for his more detailed investigations. In spite of certain excellent features in the work of Mr. Ransome at Globe (and I have had reason to appreciate this when examining certain outlying ore deposits of the Globe region), and realizing that the work was of a pioneer nature, it still seems hardly excusable that the errors, now admitted by Mr. Ransome, should have been permitted to stand as long as they have without correction. The error in placing the Schultze granite in the pre-Cambrian was a serious one, and was detrimental to certain of the early attempts to attract interest to the Miami-Inspiration ore-zone. Mr. Ransome states that evidence of the post-Carboniferous age of the Schultze granite is lacking, in the area mapped. Possibly so, but the intrusive contact of the Schultze granite with the 'meta' diabase should at least have suggested the alternative hypothesis of post-Carboniferous age. In any event, as brought out by Mr. Ransome, a reconnaissance to Troy and Ray would have proved the later age of the Schultze granite. In a report of the importance of the one under discussion, especially considering its nature as a pioneer investigation, search outside the exact limits of the area mapped, for evidence not fully presented within the limits of the sheet, would have been desirable.

Mr. Ransome's objection to my suggestion that the Schultze granite extends eastward under the Gila conglomerate and was responsible for the Globe Hill as well as the Miami-Inspiration deposits, is not sustained by the data presented by himself. He states that some of the granite near the Old Dominion mine, originally described by him as Gila conglomerate, is not Schultze granite but Madera diorite, and he goes on to describe 300 ft. of yellow granite porphyry as a dike in the Old Dominion mine, and further states that it resembles the porphyritic varieties of the Schultze granite, and was probably intruded at that time, all of which is definite evidence in favor of the conclusions advanced, evidence which I was not able to obtain, as I have not visited the Old Dominion underground workings in the last few years.

It would seem to be of value to the mining industry at large, and to its own prestige in particular, if the Survey, after once reporting on a district, would keep in touch with the same, and present the new data as they are available, and correct old mistakes promptly and frankly. For instance, the error in not grasping the importance of the dissemination in the Bingham monzonite, would be more easily forgiven, had the Survey been prompt to rectify its error of judgment by supplemental descriptions of the orebody as it was developed, and microscopical work showing the relation of the leached cap above and the dessemination below, etc. Certainly the time is ripe for a re-survey of the Globe region, a survey of the Ray district, and a study of the chalcocite disseminations which have as yet received almost no attention at the hands of the Survey.

One paragraph in Mr. Ransome's article needs cor-

rection, which reads as follows: "C. F. Tolman, Jr., deriving his conclusions mainly from unpublished work of J. E. Spurr at Ray, and W. H. Weed at Miami, has suggested that the Schultze granite is post-Paleozoic (Tertiary?)." From this statement, as well as an account of a change in the article made in editing the same, which gave the impression that I was presenting Mr. Weed's work when describing the Miami orebody, the inaccuracies of my sketch diagrams and of my rough reconnaissance work, may wrongly be attributed to Mr. Spurr and Mr. Weed. The only information received from Mr. Weed was a statement that in his opinion the Schultze granite was post-Paleozoic (Tertiary?), and belief in its post-Carboniferous age was reached independently by myself. The investigation at Ray, the results of which appeared in the article noted, were made before meeting Mr. Spurr, and discussing informally the Arizona copper deposits. As Mr. Spurr's investigations at Ray were confidential he did not of course give information as to the details of his results.

C. F. Tolman, Jr.

Tucson, Arizona, February 14.

Alfred James' Annual Cyanide Letter.

The Editor:

Sir—I would be glad of the opportunity to supplement the information conveyed to your readers on one point in Alfred James' annual letter. He says, on page 45, that he does not know of any instance where the Dehne press has been displaced by a vacuum filter. I may state that such a case occurred at the Creston Colorado mine, in Sonora, Mexico; also at the El Rayo mine, in Chihuahua, filter presses (not of the submerged leaf, but of the frame type) were displaced by a vacuum filter. In both instances the change was amply justified by results and has never been regretted.

It would also be interesting if Mr. James would inform us why, in speaking of the "fixed immersed vacuum filter" he unconditionally labels it 'non-wash'. If this is his unbiased judgment on the examples he has investigated he must have been singularly unfortunate in his choice of examples. I have had a sufficiently wide experience with this type of filter to state emphatically that the description 'non-wash' is misapplied. The filter allows of thorough washing when properly cared for and well manipulated, and I have often seen cases where no trace of soluble gold and silver could be detected by assay of the washed cake. If any users are working it as a non-wash filter they are not obtaining the service of which it is capable. I admit that the system is not perfect, but in spite of its drawbacks I believe it will hold its own against any other at present in use.

E. M. Hamilton.

Ventañas, Mexico, January 17.

The Editor:

Sir—I have read with interest 'James' Annual Cyanide Letter' in the Mining and Scientific Press of January 1, and considering that Mr. James is thought by some to be a leading light on the whole question of both the chemistry and dynamics of the cyanide treatment of ores, I find many points to criticise, which I think should be pointed out, otherwise many investors might be prejudiced in favor of some particularly patented article to an extent that it does not merit. Furthermore, I know that your paper always endeavors to handle subjects from a purely disinterested and technical point of view, and I was therefore surprised to note that Mr. James could be so small-minded as to omit the name of Butters when referring to 'fixed immersed type filters'. I am not at present interested in any of the filters, though, like most men who have dabbled with the subject, I believe I have an idea that beats the rest, so I think I can express my opinion without prejudice.

In the summary given on page 46 the 'fixed immersed type' is charged with 2d. for acid, while the others are not. This is distinctly unfair; the necessity for using an acid bath for dissolving the calcium carbonate with which the filter-cloth becomes choked, depends not on the filter but on the nature of the ore and the system of treatment. I have seen just as much trouble with the Moore filter from this source at the San Rafael mill, Pachuca, as with the Butters. The Ridgway is a filter that I admire very much, but it has its special field. I refer to the old type, as I am not familiar with the new. The valves are a serious source of trouble, and, while the results are excellent on sands from silicious ores, it fails utterly where there is a large amount of calcareous clay and what may be termed sticky 'slime'. I would classify filters in the following order of merit: (1) Dewatering filters, for dehydrating and treating sandy pulp, where a cake can be formed rapidly; Nichols, Hunt, Wilfley, and Parrish. These are not suitable for slime. (2) Continuous process filters, suitable for very fine pulp with some slime, for small units, area too small for pure slime; Grothe and Carters and Ridgway (old type). (3) The slime filters, all adapted to slime, not adapted to sand; Butters, Moore, and Ridgway (new type). Butters best where space is a consideration, Moore can be sampled better, Ridgway the most complex.

Filter presses are only suitable for rich solutions and for elastic and non-porous pulps, and for cleaning up and pressing precipitates from the zinc boxes. Filter presses cannot compare with vacuum-filters for economy of operation.

What we really need is a table of statistical data which will show the following facts when each filter in turn is put through the same series of tests on ores of widely different nature:

Total area in square feet of filter-surface per machine; capital cost per square foot area; gross weight per square foot of surface; interest on capital-cost; depreciation and repairs per square foot of surface; air required and vacuum-curve at all stages; filtering capacity in dry slime per 'hour square-foot surface'; current costs, that is, power for air; labor, filter-cloth, acid bath, etc.; percentage of moisture in pulp before filtering, and percentage after filtering.

An extraction percentage without comparing the above factors is misleading, because the extraction is more largely dependent on the chemical part of the process, the dynamics of fine grinding, and the

method and time of agitation, then on filtering. The filter is merely a remover of solution.

I also notice a feature referring to crushing on page 42. Mr. James states that on the Simmer Deep there was an increased efficiency in crushing when using less water; but the comparison was made after the addition of tube-mills, and it is not shown whether the increased efficiency were due to the step-reduction, or to the increased efficiency of both stamp-mills and tube-mills, with less water. This is important. My own observation shows that the crushing capacity of stamps increases with an excess of water, and also with increase of screen-area by the use of multiple screens, but decreases in a tube-mill; therefore dewatering should be the rule between the stamp-mill and the tube-mill.

Data are lacking on the efficiency of multiple-discharge mortars. I am certain that they would be of great use in a silver mill using concentration and the cyanide process. I also wish to take this opportunity of drawing attention to certain remarks made by Mr. James, in regard to the Brown agitators (which are more generally known here in Mexico as Pachuca tanks), especially with regard to the suggested Grothe-Mennell continuous treatment which he disposes of in a few words. At the top of the first column on page 43 he refers to "a system of continuous decantations." Does he mean this in reference to the Grothe-Mennell process, or is it merely a case of ambiguity? If the latter, it is certainly serious, considering the authority that Mr. James' words carry, for his statement might be taken as final by some young metallurgical engineer about to design a mill. If, on the contrary, he refers to the former, then Mr. James should read up more thoroughly before seriously putting pen to paper for an annual letter. Grothe-Mennell never suggested a system of 'continuous decantation' (?) sic: I beg to draw attention to an article by Leslie Mennell on page 15 of the February issue of 1909 of the *Mexican Mining Journal*, in which this suggested process is thoroughly described and data regarding a series of experiments are given, from which I take the liberty of making the following precis: "In the system of continuous treatment a series of tanks is placed at the same level; the pulp, however, is maintained at a slightly lower level in each succeeding tank of the series, the drop from first to last being just sufficient to allow the pulp to flow through the series at the same rate that it is being charged into the first tank; * * * as the finished product discharges from the last tank at approximately the same level as the intake, it then proceeds by gravity to the filter plant."

It is clear that in this manner all of the time now virtually lost in filling and emptying tanks is saved, and all tanks are constantly and usefully employed in cyanide agitation. Will Mr. James kindly explain what he means by 'continuous decantation'. Judging by my own training in metallurgy, the term 'continuous dewatering' or 'dehydrating' would be admissible, but 'continuous decantation' would be impossible. The generally accepted procedure here in Mexico is to use the Pachuca tanks solely as an agitator, and to trust entirely to vacuum-filters to remove the solutions, even non-continuous decantation being only practised in the large-diameter, low-height vats used with mechanical agitators.

Referring to the test and experiments of Mennell, an exact miniature of the standard Pachuca tanks was used. The first test was by the standard intermittent process. The ore was of silver, the metal being present as a sulphide, the more refractory being associated with slimed galena and iron pyrite which had escaped concentration; this with iron oxides and a little zinc blende caused a considerable consumption of cyanide. I have taken the following from the *Mexican Mining Journal*:

The test on this ore by the ordinary system, agitated for 48 hours, gave the following results:

OLD INTERMITTENT PROCESS.

Amount of finely crushed ore used, kilos	Amount of solution, kilos	Time agitated, hr.	Strength cyanide solution, %	Consumption cyanide kilos, per ton	Head value silver grams, per ton.	Residue value silver grams, per ton	Extraction, %
70	100	0	0.39	0	349	...	...
		12	0.26	1.86		118	66.0
		24	0.20	2.71		108	69.0
		36	0.13	3.76		98	71.2
		48	0.12	3.86		95	72.7

The second test was made using four of these same tanks connected in series as described. Pulp was fed at the rate of 70 kg. per day with 100 kg. of solution, this being the amount of the individual capacity of the tanks. The operation was continued for 8 days; after 5 days, when the process was running perfectly uniform, samples were taken from each tank and assayed. Samples were taken frequently up to the eighth day. The whole test is shown as follows:

NEW CONTINUOUS SYSTEM.

Amount of finely crushed ore fed daily, kilos	Amount solution fed daily, kilos.	Number of tanks.	Time of treatment, hours	Strength KCN solution, %	Consumption KCN kilos, per ton	Head value silver per ton, gm.	Residue value silver per ton, gm.	Extraction, %
70	100	..	0	0.39	0	325	...	...
		1	12	0.30	1.29		146	58.0
		2	24	0.26	1.86		122	68.0
		3	36	0.20	2.71		101	71.3
		4	48	0.18	3.00		80	77.3

Assay of entire discharged residue was 80 gm. silver per ton, with an extraction of 77.3%. For full data on the subject I refer to the article mentioned, but I have shown enough to indicate that the subject should not be dismissed with a wave of the hand by a cyanide expert whose knowledge, while extensive, is not absolute. I trust that the above notes will be of value to some of my co-workers.

JOHN M. NICOL.

Mexico City, January 20.

Timber to the amount of 4.5 cu. ft. per ton of ore is used at the Bodie mine, while at the Ontario 100 tons may be produced using only 6.25 cubic feet.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Pig iron production in the United States in 1909 amounted to 25,795,471 tons as compared with 15,936,018 in 1908 and 25,781,361 in 1907.

Performing assessment work upon a claim without 'discovery' will not prevent adverse re-location. Marking the boundaries, coupled with actual possession, and continual exploitation or continued prospecting of the ground in good faith for mineral, will hold a claim without discovery.

Humidity of air is the pounds of water carried by 1 lb. of air when saturated at a given temperature and pressure, and percentage humidity is the weight of water actually carried by a pound of air divided by the maximum that could be carried by the pound of air under the same conditions.

Under the last mining act of California a mine-owner who fails to make the annual expenditure upon his claim is disqualified from re-locating the ground embraced in the original location or mining claim, or any part thereof under the mining laws within three years after the date of his original location. Any attempt at re-location thereof by any of the original locators renders such location void.

Iodine in the nitrate deposits of Chile is attributed to decaying marine plant-life in the shallow sea once covering the region now constituting the saline deserts, according to R. A. F. Penrose, Jr. While it may have come from mineral springs, such an origin is unlikely and unproved. If a greater demand should be made for iodine great quantities could be produced from the waste liquors in the saltpetre factories. Iodine can be used advantageously as an 'oxidizer' in the cyanide process.

Timber cut when the flow of sap is least shows the greatest strength. There is also material gain from drying the timber before use. Water absorbed does not impair strength as does the fluid in the cells of the wood. It is the elimination of the latter moisture that is sought by drying. Timber uniformly wet throughout is relatively stronger than if one part be dryer than the other. Trunk-wood is greatly superior to limb or sapling wood, both for strength and durability. Sawed lagging is therefore better than pole-lagging.

Mine rescue apparatus of the compressed oxygen type permits a person wearing it to breathe naturally with little inconvenience for a continuous period of two or three hours, even while surrounded by deadly or irritating fumes, smoke, or other irrespirable gases. The principal features of such an apparatus are the tanks or cylinders containing the oxygen under high pressure, absorption cans for taking up the oxygen exhaled from the lungs, and a helmet or mouth attachment with breathing bags, which enable the person wearing the apparatus to breathe with ease. The foregoing features are accomplished in different degrees of efficiency by different types of apparatus.

Semi-monthly steamboat service has been inaugurated between Iquitos and Yurimaguas, Peru, a distance of nearly 900 miles. Iquitos, the capital of the Department of Loreto, is on the Amazon, while Yurimaguas is on a tributary, the Huallaga. The enterprise is undertaken by the Cia. Anónima de Alto Amazonas, which has connections with the down-river steamers at Iquitos. This will afford easier communication with a region in north-central Peru which contains some valleys rich in placer-gold.

Tungsten finds its most important use as an alloy for steel, to which it imparts the property of holding temper at a much higher temperature than high-carbon steels. When lathe tools are made of tungsten steel the lathe may be speeded up until the chips leaving the tool are so hot that they turn blue. It is said that about five times as much work can be done by a lathe built for such speeds and work and fitted with tungsten-steel tools as can be done by the same lathe with carbon-steel tools. From 16 to 20% of tungsten is ordinarily used in lathe tools.

Gypsum is being used extensively as wall plaster (hard plaster) and in cement, as well as for minor uses, such as in stucco and as a fertilizer. This has created a large demand for knowledge of gypsum deposits. In most States such knowledge is more easily obtained than in California, where the gypsum deposits are largely in long stretches of sparsely inhabited regions in the nearly arid territory along the east side of the Coast Range and in the Mohave and Colorado deserts. The area has been recently described by F. L. Hess, of the U. S. Geological Survey.

Platinum is constantly being reported from the placers and dredging areas of the California gold belt. It now seems questionable whether this so-called 'platinum' is not largely iridosmine. A recent shipment of metal from Oroville, supposed to be platinum, turned out to be wholly iridosmine. The amount was 31 oz., resulting as a by-product from the treatment of approximately one million cubic yards of gravel, and was paid for at the rate of $18 per ounce. The metal is obtained by washing the skimmings from the amalgam in a rocker, after previously removing the bulk of the iron with magnets.

Leaching of copper ores has never been conducted to a large extent. The most successful efforts, applicable to oxidized ores, consist in leaching with dilute sulphuric acid, subsequently precipitating the copper in vats on scrap-iron. Certain classes of friable copper-bearing iron-pyrite ores, such as those obtained at Rio Tinto, Spain, can be leached by natural rainfall, the ore being stacked in heaps several feet high, on yards with a tamped clay bottom. The gradual oxidation by such weathering forms the sulphate which is soluble and leaches out. In default of adequate rainfall, the heaps are wetted with water from pipes. Care has to be taken to prevent spontaneous ignition of the heaps from too rapid oxidation. The copper-liquor is drained off to boxes where it is precipitated on scrap-iron.

Special Correspondence.

TORONTO, CANADA.

Porcupine and Elk Lake Districts. — Cobalt Quiet. — Nickel Inquiry.—Newfoundland Iron-Ore Royalties.—Canadian Steel.

The principal interest in mining matters still centres in the Porcupine gold camp, where some important events have lately taken place. M. J. O'Brien, the Cobalt millionaire, who undertook diamond-drilling operations on the Miller claim, one of the star prospects of the camp under a $300,000 option, threw up the contract on which he had paid $1000. It is understood that he asked for an extension of time so as to make further explorations, not being altogether satisfied with results, and as an alternative proposal offered $100,000 for the property, both of which offers were refused. Any discouraging effect which this transaction may have had on prospectors and speculators has been quickly dispelled by the consummation of a considerably more important deal a few days ago, the McCornick Brothers, of New York, having purchased the Wilson claims comprising 11 locations about two miles southwest of Porcupine lake for $1,500,000, after their representative, Mr. Geddes, had spent about two weeks examining the properties. The Provincial Government is laying out a new townsite at the northeast end of Porcupine lake to serve the requirements of the district, and town lots will shortly be offered for sale. The new mining district of Porcupine has been established with Arthur E. B. Bruce, late of Haileybury, as recorder in the new town of Porcupine. The gold area is being extended, new discoveries having been made within 17 miles of Matheson, and 3½ miles east of Night Hawk lake. The Elk Lake district, which was expected to be a second Cobalt, has proved a disappointment, and few, if any, of the numerous companies floated a year or so ago are likely to return anything to the investors. Two of them, the Otisse-Carrie and the Gavin-Hamilton, are now in process of liquidation. Each of these concerns had a nominal capital of $1,500,000 and paid $1,000,000 for the respective properties. The Reeves-Dobie Gowganda district has made a second shipment of 32 tons of ore, bringing the total shipments from this district since January 1 up to 92 tons.

Cobalt stocks continue depressed, the outside public having apparently lost all interest in the market, as a result of the general slump in New York stocks. There is not likely to be much change for the better until the camp obtains cheap power. This was promised long ago, but has been deferred from time to time. Apart from this cause, the passing or reduction of dividends by leading companies, litigation, and the diversion of capital to newer fields are quite sufficient to account for the prevailing stagnation. Shipments for the first four weeks of 1910 amount to 1896 tons, of which La Rose furnished 350 tons and Nipissing, 336 tons. The La Rose is preparing to install a new power system, which is expected to reduce the cost of power to half the present figure. Some of the smaller La Rose properties are showing up better under development. Veins from adjacent properties have been traced to the Fisher-Eplett and the indications on the Princess and University are improving. At the Bailey mine the new power-plant, to operate six drills, has been installed. At the Hargrave stoping is now being done on the No. 3 vein entering from the Kerr Lake, the ore averaging 3000 oz. per ton. No. 1 vein has been opened up to the 75-ft. level where 6 in. of good ore has been found. The shaft will be sunk to the 150-ft. level. The financial statement of the Nipissing shows a cash surplus as of January 1, 1910, of $1,322,985, as against $920,510 on January 1, 1909. Dividends paid for 1909 were $1,500,000, as against $840,000 in 1908. The ore shipments last year amounted to 6510 tons of the net value of $2,210,364. The Cobalt Lake mine has shipped 66 tons valued at about $30,000 from the new veins at the south end of the lake, near the McKinley-Darragh line that show marked improvement. A winze has been sunk from the 190 to the 250-ft. level, and an adit will connect the other veins and the shaft. The McKinley-Darragh concentrator is being extended so as to give a capacity of 120 tons per day. The Beaver mine has been temporarily closed for the enlargement and timbering of the shaft. Several new buildings are being erected on the property. The Trinity mine has been sold under liquidation proceedings against the company, the purchaser being Henry E. Jungling, of Buffalo, New York.

The Mines and Minerals Committee of the House of Commons, Ottawa, is conducting an enquiry into the nickel resources of Canada, there having lately been some agitation in favor of an export duty on nickel ore and matte so that the whole process of refining may be done in Canada. At present the nickel is exported in the form of matte to the refinery in New Jersey. It has been contended that the International Nickel Co., which controls most of the Sudbury output, is practically a trust and restricts the supply in order to maintain the price. A. P. Turner, president of the Canadian Copper Co., the Canadian branch of the International, was heard before the committee on January 2. He denied that any trust existed, pointing out that the Mond Nickel Co. and the French Nickel Co. were competitors. The refining of nickel was done to the extent of 82% in Canada, and the company had spent $250,000 in experiments in order that it might be enabled to complete the refining process in Canada. At present it could not profitably do this and was obliged to ship in the form of matte to New Jersey, owing to the necessity of using certain chemicals, including salt cake, in the proportion of more than ton for ton. This was a by-product of some of the New Jersey factories. To do any further refining in Canada would render it impossible for the company to compete with the New Caledonia ores. Other evidence was adduced to the effect that it was only recently that the investment in nickel manufacturing had proved remunerative, the present return being only 6%. The Government of Newfoundland has imposed a royalty of 7½c. per ton upon the output of the hematite ore mines of Bell Isle, which furnish a source of supply for the furnaces of the Dominion Iron & Steel Co., and the Nova Scotia Steel & Coal Co. The production amounts to about 1,000,000 tons per year. André Weill, of Paris, a representative of the Creuzot Steel Co. of France, has been for some time at Ottawa looking into the possibilities of the steel industry in Canada. It is understood that the French company, which is controlled by the Rothschilds, contemplates the establishment of an electric smelting plant at some point in Canada, and Mr. Weill has been inspecting a number of water-power sites in the Ottawa district, and has held several interviews with leading public men in connection with the project.

GLOBE, ARIZONA.

Miami Copper Co.—Inspiration.—Old Dominion.—Arizona Commercial.—Lost Gulch.—Lake Superior & Arizona.

The Miami Copper Co. has 40,000 ft. of driving and crosscutting on its property, six miles west from Globe, 29,000 ft. of which was driven in 1909, developing great bodies of chalcocite in a gangue of Pinal schist. This ore averages 2¾% copper, and is said to extend through a vertical depth of 400 ft., that is, between the 230 and 620-ft. levels. Operations are carried on through four vertical shafts: No. 1, or Redrock shaft, started in the apex of the orebody, has reached a depth of 720 ft.; No. 2, Red Springs, is 2500 ft. from No. 1, and at a depth of 460 ft.; No. 3, known as the Captain, 850 ft. west from No. 1, is 220 ft. deep; No. 4, to be the principal working shaft, is down 535 ft., and is to be continued to a depth of 700 ft. It is 12 by 16 ft., 4-compartment, timbered with creosoted 12 by 12-in. timbers. This shaft is sunk off the orebody, in conglomerate, and is connected with shaft No. 1 on the 420-ft. level. No. 1 and No. 2 are connected on the 470-ft. level. The ore is to be hoisted from shaft No. 4 in two 7½-ton skips by a hoist operated by compressed air from the power plant. The skips are to be loaded from two 1000-ton ore-pockets, one just below each of the two main working levels. Each pocket is being equipped with a measuring box, holding the exact load for the skip, the loader being manipulated by a compressed air operated gate. Electric haulage is being pro-

vided on the two main levels for delivering the ore to the loading pockets. It has been estimated by the company's engineers that 700,000 tons of ore can be mined in a year.

The concentrating mill is under construction and probably will be in operation before the close of this year. The mill-site is an advantageous one, on the east slope of the hills, in close proximity to No. 4 shaft. Next to the shaft are the bins which are to receive the ore from the skips. Adjacent to the bins is the coarse-crushing plant, consisting of two No. 7½ gyratory crushers, and two sets of rolls, each 54 by 24 in., whereby the ore is reduced to 2-in. cubes. Between the crushers and rolls are two 4 by 10-ft. manganese trommels for sizing. The ore, reduced to this size, will be delivered by a 300-ft. belt-conveyor to the sampling plant, thence by conveyor to six cylindrical steel bins of which there is one for each section of the mill. Each bin is 30 ft. diam., 30 ft. high, set 24 ft. above the ground upon a concrete foundation, and has the capacity of 1000 tons of ore. The bins are to be provided with automatic weighing and sampling devices, whereby the weights and samples of ore going to the different mill units may be checked against those of the sampling plant. The ore is to be drawn from

Globe in Relation to Physiographic Regions of Arizona.
(After Ransome, U. S. Geol. Survey.)

each cylindrical bin by a conveyor to the section of the mill opposite it, passing first to a set of rolls which reduces it to ⅛-in. size. It is then to be classified by 22-mesh screens, the oversize going to two Chilean mills having 30-mesh screens. The product of the Chilean mills unites with the undersize from the 22-mesh screens, passing thence to classifiers, the coarse product going to sand concentrating tables, and the finer material to slime tables. There are to be 20 sand tables and 30 slime tables to each of the six mill units, the aggregate capacity of these units to be 2000 tons per 24 hours. H. Kenyon Burch, the company's mechanical engineer, who designed and is directing the construction of the mill, states that the ore will concentrate in the ratio of about 18 tons into 1 ton. The entire foundation of the plant is of concrete, in which there are 15,000 cu. yd. of cement work, which was laid at the rate of 300 cu. yd. per day. The mill structure is of steel, there being no woodwork in the plant except that used in the system of launders.

The power plant, under construction, has a site at the base of the hill on the flat surface of the valley, close to the railroad. This plant is being housed in a concrete steel building, 264 by 70 ft. in size. The concrete stack, having a 12-ft. flue diameter, will be 200 ft. high. There will be installed four 600-hp. Edgemore water-tube boilers, which will generate steam at 200-lb. pressure. These will have Green fuel economizers and Foster superheaters to superheat steam at 100°C. Oil is to be used as fuel. The other equipment will consist of three 4-cylinder, tripple-expansion Nordberg engines, direct-connected to that number of 1000-kw. electric generators, each 3-phase, 25-cylinder, generating 6600 volts; also two 4000 cu. ft. air-compressors, 4-cylinder, tripple-expansion, Nordberg type; and two direct-acting counter-current, jet-condensing engines. Close to the power plant are towers for cooling the circulating water. The mill machinery is to be operated by electric motors advantageously distributed throughout the plant. Water for mill work and other purposes will be obtained from the Old Dominion mine at Globe, and this will require a pumping plant and a line of 4-in. pipe 25,000 ft. in length. O. D. Lawton is superintendent of the mine, and B. Britton Gotzberger general manager.

The Inspiration Copper Co., whose group of 444 acres lies contiguous to the Miami on the west, has a length of about 5000 ft. on the same mineralized zone as the latter. The width of the zone on the Inspiration is not fully determined. The mineralized area is in schist, having intrusions of granite-porphyry, and a dacite overflow. The ore is composed of chalcocite in a schist gangue, as is the case on the Miami. Explorations by churn-drills on the Joe Bush and Pinto claims, on the eastern part of the group, indicate a thickness of the orebody of 400 ft. One drill-hole is down 718 ft., another 600 ft. The average depth of the numerous holes is 450 ft. These tests show that below the chalcocite zone is an unaltered deposit of copper-iron sulphide, some of which might be mined. The Joe Bush shaft, down 400 ft., and the Scorpion, 300 ft. deep, are 1700 ft. apart, on opposite sides of a mountain ridge. Driving is in progress on the 400-ft. level of the former and also on the 275-ft. level of the latter. An adit level is being driven northerly from Keystone gulch. To facilitate this work a Sullivan air-compressor and drills have been installed there. This adit will be driven 2300 ft. through granite-porphyry before it strikes into the orebody. It is to become a working level for a large body of ore above it. The entrance to this adit is one mile from the railroad. T. R. Drummond, manager for the company, states that Inspiration ore does not differ materially from that of the Miami. It is observed that the chalcocite in all these ores occurs in coarse highly concentrated stringers and in finely disseminated particles. The New Keystone Copper Co., under the same management as that of the Miami, has been for some time developing from a shaft and exploring with two churn-drills its group of copper-bearing claims adjoining the Inspiration on the southeast. This work is in charge of E. B. Tinker. The Boston-Miami, next to the Light Hope and Keystone, is controlled by F. W. Hoar and associates, forming a close corporation. Their holdings comprise 42 claims in a body. Exploration is in progress with two Star drills, now on their sixth and seventh holes, the depth of the holes drilled being 550 to 600 ft. A force of 42 men is employed.

The Old Dominion Copper Mining & Smelting Co., now under the general superintendency of G. H. Dowell, is mining 600 tons of ore per day, 350 tons of which are concentrated in the ratio of three to one. The two furnaces of the smelting plant which are in operation are treating 400 tons per day of ore and concentrate, the total charges amounting to 650 tons. The smelting ore runs 8% copper, 35 to 37 iron, 13 sulphur, and 35 silica; the milling ore, running lower in iron and higher in silica, carries 3½ to 4% copper. In the smelting practice the converter slag is used as flux instead of lime, the composition of which is 33% silica, 50 iron, and 2½ copper. The blast-furnace slag contains, approximately, 38% silica, 44 iron, 10 alumina, and 3 lime. L. O. Howard, superintendent of the smelter, states that instead of using barren clay for converter lining they utilize the slime from the mill. A new Nordberg steam-pump has been installed at shaft A, this and other pumps in use now lifting 2½ million gallons of water every 24 hours. A new hoist has been ordered for this shaft, which has a depth of 1400 ft. George Kingdon is mine superintendent. The Old Dominion company employs about 1000 men at mine, mill, smelting plant, and shops.

The Copper Hill section of Globe district, 3½ miles northeast of the town, is in a country of diabase, limestone, and

quartzite, in which well defined lodes of copper ore occur. The principal mine operators there are the Arizona Commercial Co. and the Superior & Boston Copper Co., whose properties are situated near each other. This part of the district is now served by the railroad of the Arizona Commercial Co.; and that of the Arizona Eastern, whose line to Copper Hill is nearly finished, will soon be operating trains. The latter is a part of the Southern Pacific system. The Superior & Boston, for which Frank H. Probert is consulting engineer, and for which John D. Wanvig is superintendent, has 54 claims in a group, on which there are five veins having a strike nearly east and west. Three of these are said to have ore of commercial value developed. The two of most importance, apparently, are the Great Eastern and Old Dominion, which are 1000 ft. apart. The former has a diabase hanging wall, a quartzite foot-wall, and a dip of 60°. The latter dips 88° south, is between diabase walls down to a depth of 400 ft., below which it has a diabase hanging wall and a limestone foot-wall. The ore is much oxidized, but contains a good deal of chalcocite. It contains, as a general average, 25% iron, 45 silica, and 10 copper, with 8 oz. silver per ton. The McGaw, sunk to a depth of 580 ft. between these two veins, is the principal working shaft. It sinks in the foot-wall of the Great Eastern; the first 450 ft. is in diabase, the remaining 130 ft. being in limestone. The shaft has two 4½ by 5-ft. hoisting compartments, and one 5 by 7-ft. compartment for air and water pipes. The timbers used in the shaft are 10 by 10-in.; there is a special collar-set, having a 3-ft. runway around the shaft to give rigidity and to facilitate the handling of heavy machinery. Levels are run to the Great Eastern vein from the fourth and sixth stations. The Old Dominion vein has been opened by a cross-cut from the shaft on the fourth level, and the plan is to develop this vein on the sixth level. Sinking below the sixth level is being resumed in the McGaw shaft. The surface equipment consists of a Nordberg double-drum geared hoist capable of operating to a depth of 1200 ft.; a 13-drill air-compressor, same make; two 250-hp. Sterling boilers, and two more of like capacity are being installed; a Prescott duplex triple-expansion pump, capacity 1000 gal. per minute, being installed at sixth level; also three Prescott sinking pumps now in use. The Black Oxide vein is being developed through the Gardner shaft. On the fourth level a drift is being run on the vein to strike a shoot of ore that was opened by an adit which was driven at a higher level. The ore here is similar to that found in the Great Eastern, excepting that it runs higher in iron. This company is shipping 50 tons of ore per day at present to the smelting plant of the Arizona Commercial Co. The latter company is mining and smelting 225 tons of ore per day from its Black Hawk vein, which is identical with the Great Eastern vein on the Superior & Boston. Added to this daily tonnage is 50 tons from the latter property and 50 of sulphide ore from the Copper Bell mine at Gleeson, in Cochise county. The Black Hawk vein is opened by the Eureka shaft, sinking 713 ft. in the hanging wall, the first 400 ft. of which is in diabase and the rest of the way in limestone. The shaft cuts the vein on its dip between the 600 and 700-ft. levels, the 700-ft. station being in the foot-wall. The vein on this property has a dip of 53° and a width ranging from 6 to 40 ft. The ore is mostly oxidized, carrying 30% iron and 4 to 10 copper; the iron consists of hematite and limonite. Chalcocite, occurring in irregular bodies from 6 in. to 3 and 4 ft. in width, is found in the carbonate body. It is said that most of the material between the walls is sent to the furnace. The smelting plant equipment consists of a 180 by 48-in. blast-furnace, a No. 9 Connersville blower, the latter operated by a tandem compound Nordberg engine; two Babcock & Wilcox boilers, 700-hp., using oil as fuel. The dust chamber is of the usual type, the steel stack is 8 ft. diam. and 125 ft. high. J. E. Penberthy, general superintendent, states that the furnace may be extended in length, thus doubling its capacity. When this is done a new stack will be built, and possibly a converter plant added. The smelter has been in operation since October 15, 1909, with E. L. Williams in charge. The 50% matte produced is sent to the converters of the Old Dominion plant. The furnace charge ranges from 350 to 400 tons per day. This company is closely allied to the Shannon Copper Co., operating at Clifton, J. W. Benny being general manager for both companies.

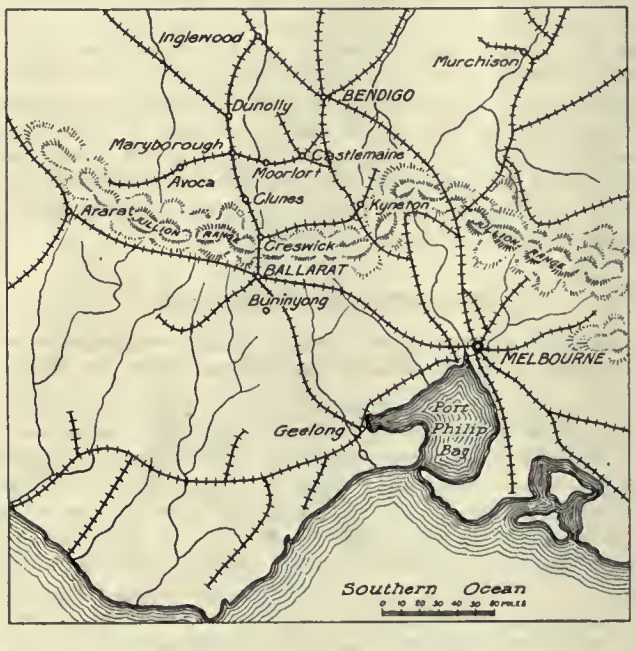
The Lost Gulch United Mines Co., whose property is seven miles west from Globe, is completing a 10-stamp mill, having plates, tables, and vanners, for milling its ore, which carries gold, silver, lead, and copper. The highest grade is sorted out and shipped direct to the smelting plants. J. T. Harrington is one of the principal interested parties. The property of the Lake Superior & Arizona Mining & Smelting Co., situated at Superior, half-way between Globe and Florence, has been closed, except as to pumping operations, for several months pending the further financing of the company that will enable it to resume operations. According to data obtained from F. W. Hoar, the company's manager, the mine is opened to a depth of 1300 ft. on an incline, giving a vertical depth of 650 ft. The ore-bearing lode, 40 to 50 ft. in width, has a limestone hanging wall and a quartzite foot-wall, with diabase dikes intersecting the lode. The pay-ore, which runs about 5% copper and $3 to $4 per ton in gold, occurs in lenses, some of which are said to be 1000 to 1500 ft. in length. The ore is oxidized to a depth of 1200 ft. on the dip of the vein, and at this level the sulphides come in. When work is resumed, the idea will be to sink 200 to 300 ft. deeper to obtain a supply of sulphide ore to mix with the oxides and carbonates already developed. On the results of this proposed work will depend the proposition to build a railroad to the mine and erect a smelting plant there. The mine shaft is close to Queen creek which, at times of freshets, would empty a part of its volume of water into the mine. To obviate this a cement flume, 800 ft. long, 34 ft. wide, 10 ft. deep, was built on the bed of the creek to carry the entire flow of the stream past the points where channels led into the shaft.

MELBOURNE, VICTORIA.

A Quietly Prosperous Year.—Output for 1909.—Cyanidation.—Electricity in Mining.—Bendigo and Ballarat.—New Coal Mines.

If the position of gold-mining may be accurately judged from recent actual yields, then it must be said plainly that in Victoria results are somewhat disheartening, though by no means desperate. It is no longer news that the enormous yields of the early days, say from 1862 to 1875, are affairs of memory and record only; in those golden years the output never fell below a million ounces, while in most of them it exceeded a million and a half, and once approached a million and three-quarters. But if the returns of the past fifteen years be compared with the ten years between 1885 and 1895, during which the year's output once fell as low as 576,399 gross ounces and never exceeded 735,218 gross ounces, things are not now so bad as they have been, though they appear to be on the down-grade again. These figures, it may be stated, are gathered from the Victorian Mines Department, which, for no particular reason, has set its teeth against recording yields in fine ounces. In 1906 the gold harvest amounted to 834,775 oz.; in 1907 it was 754,270 oz.; in 1908 it was 721,220 oz.; and for the first nine months of 1909 it was only 488,087 oz. This rate of production would give only 650,788 oz. for the whole year. The fact is that no new goldfields have been opened up, as has been done in some other States, in which the old ones are giving greatly reduced yields. Here and there, certainly, some good mines are being worked; wonderfully rich patches have been struck, which even promise a return of palmy days, but it is unsafe to predict a long continuance of their prosperity. The great bulk of Victorian gold has been obtained from quartz veins, and in many parts 'indicators' have been found which have proved extremely rich. One such was struck during the past year at Ballarat East, which will be referred to later on. In certain other portions of the State the deposits are alluvial, such as those at Creswick, on which the great Berry group of mines worked and are still working, and the deep-lead mines of Chiltern and Rutherglen, while a large quantity of the precious metal has been secured by dredging, notably in the Castlemaine and the Ovens Valley (Bright) districts. Indeed no branch of the gold-procuring industry in Victoria

has been so markedly successful of recent years, or has been so remunerative to the companies engaged in the pursuit, as the dredging of the banks and beds of certain of its rivers and creeks—water-courses which are quite unnavigable, and therefore useless for all other purposes except as supplying drinking water for live-stock and occasionally for irrigation purposes. During 1908 the dredges secured no less than 104,167 oz. gold, and in the previous year the recovery was 100,215 oz.; and after paying £305,060 in wages and other costs the companies paid £63,784 in dividends. A comparison of the figures for the years prior to 1900 and between that year and 1908 will show the enormous advance made in gold-gredging in the interval. Prior to 1900, 430 acres had been so dealt with for a return of 90,528 oz., whereas from 1900 to the end of 1908, 3738 acres had been covered, 109,031,108 cu. yd. of material being treated for a recovery of 549,143 oz. In 1908 the number of dredging plants in operation was 123, employing 2435 men, and they put through upward of 20½ cu. yd. of dirt for a return of 104,167 oz. gold, valued at £416,670, and averaging 2.4 gr. per cubic yard. One company alone, the Tewksbury Amalgamated G. D. Co., of Bright, obtained 8851 oz. last year, valued at £35,890, from 2,150,600 cu. yd., and paid £17,698 in dividends. The average value of the ground treated by the



whole of the dredges in the State in 1908 was only 2.43 gr. per cubic yard, but the Enterprise Dredging Co., also at Bright, paid £3000 in dividends on material which gave only 1.7 gr. per cubic yard, and a couple of other companies returned something to their shareholders on an even poorer recovery. Yet there is some danger that this highly lucrative industry may be seriously hampered at no distant date by the agitation of farmers and graziers who complain, and perhaps, justly, that the streams are polluted for their purposes. Of course it is impossible to dredge a river without stirring up the mud. In consequence of the onslaught of the agricultural and pastoral interests, P. N. Tewksbury, the most prominent and successful of the dredging promoters, recently turned his eyes to South Africa and probably in a short time he will have plants working there, where conditions are less antagonistic.

For the most part Victoria's auriferous material is free-milling, and, in consequence, the old stamp-battery or the hydraulic nozzle supplemented by cyanidation is still the customary means of dealing with it, and modern metallurgical methods have not been called for. Cyanidation and chlorination are, however, steadily increasing in favor for the treatment of concentrate and tailing; many old tailing heaps at workings long since abandoned are now being diligently exploited by the cyanider, with good results. A few years ago the Victorian Government purchased the patent rights of the cyanide process with respect to its own territory, and after all the royalty has been paid, the use of the process was made free to anyone in the community who cared to use it and provided himself with the necessary plant. In 1906 only 145 cyanide plants were operating; the following year there were 212, and in 1908 the number had increased to 289. The material treated was, for the most part, old tailing, the refuse of pre-cyanide days, and last year nearly a million and a quarter tons were made to give up 77,245 oz. of gold. If recent improvements in metallurgy have not been generally adopted by the Victorian gold-mining companies, some of the big companies have availed themselves of the numerous applications of electricity to mining purposes. To take only two or three in illustration: The Cassilis Gold mine, at Tongio West, Gippsland, possesses the most complete electrical mining plant in Victoria, erected at a cost of over £21,000. Previous to its erection the firewood bill alone amounted to £500 per month, and it was estimated that the savings that would be effected in this and other directions by the first section of the hydro-electric plant would pay off its initial cost in less than three years, while the second section was expected to return a considerable revenue by surplus power which would be available for sale to other mines. The fuel bill for the last half year was only £1167. The Long Tunnel Gold Mining Co., Walhalla, has a complete and efficient system of electrical pumps, some being employed in pumping water from the mine and others in bringing clean water a distance of nearly three miles from the Thomson river, for use in the boilers and the battery. The three pumps in the mines have each a capacity of over 6000 gal. per hour and a lift of 1000 ft.; the water-supply pumps are calculated to give at least 16,000 gal. per hour, and they are of the same type as those in the mine, consisting of a horizontal three-throw pump, driven through spur-gearing from a three-phase squirrel-cage motor mounted on a common bed-plate. The plant is driven by a non-condensing Allen engine and the fuel-cost of water lifted 500 ft. is less than 1½d. per 1000 gal., though interest and other charges bring the cost to approximate double that figure. The New Moon Gold Mining Co., at Bendigo, found about four or five years ago that a special effort was necessary if the mine were to be kept going. The management had large quantities of low-grade ore to deal with, averaging less than 6 dwt. per ton, and it was decided to introduce electricity for various purposes. The installation now includes plants for hauling, winding, pumping, crushing, and lighting. The ore, when brought from below, is fed directly into the crushers from which in due course it is transferred to the battery without handling, so that surface expenses are reduced to a minimum.

In spite of the facts that the Bendigo goldfield is the oldest in Victoria and that already more than 18,000,000 oz. of gold have been produced from it, it affords more promising opportunities for prospecting than any other district in the State. A great deal of attention has been given to deep mining, some of the workings being over 4252 ft. from the surface, and in their efforts to go downward many of the companies have left shallow ground unworked. Of recent years some of the most flourishing mines have been successfully operating the shallower ground, for example, the Hercules & Energetic, the Garden Gully, and the Horwood & Burrowes mines. At the present moment an effort is being made to open new ground along what are known as the 'side-lines of reef', lines running parallel to and intermediate between the main veins on which most of the work has hitherto been done. These have been left practically untried until now, but there is good reason for believing that they will be great gold-producers when properly and systematically worked. The Ballarat field also appears to be entering upon a period of renewed youthfulness and productivity, due also to the breaking of fresh ground. For some reason or other the quartz deposits to the north of the city have always been neglected, and it was only a few months ago that the Ballarat Citizens' Prospecting Co. was formed to attack this ground. After sinking to a depth of 360 ft. cross-cuts were put out, and on driving eastward a fine body of ore was cut from which a trial lot of 200 tons give close upon half an ounce per ton; since then the company's ground has been divided and a second company formed to work the southern portion. At Ballarat East, also, promising development has taken place where a small com-

pany was fortunate enough to strike a rich indicator, abounding in nuggets ranging up to 500 oz. each, and in the space of a few months the shareholders have been repaid considerably more than the capital invested. This vein has been found to extend into ground immediately taken up by other companies. Another promising feature of these mines is that the managers of several have succeeded in handling their low-grade ore at a profit, and when other managers have learned the lesson and modernized their plants, hundreds of thousands of tons of similar material standing in stopes will be turned to profitable account. The Pitfield Plains-Berringa division of the Ballarat district also furnishes some good returns, though mainly below those of 1908; the Birthday mine was not working full time during 1909, and for the nine months produced only 491½ oz., as against 1928½ oz. in 1908, but the Birthday Tunnel mine, which in 1908 yielded 6934 oz., gave 5365 oz. up to the end of September, while the Kangaroo gave only 1117 oz., compared with 2570 oz. last year, and Williams' Fancy produced 2953½ oz., as against last year's output of 4389

Gold mining is, of course, the main mining industry pursued in Victoria, though the known mineral deposits are numerous, the official list being as follows: agate, antimony, arsenic, barytes, bismuth, chromite, clay (pottery), coal (black and brown), copper, corundum, diamonds, diatomaceous earth, fluorspar, gypsum, iron, jasper, kaolin, lead, limestone, manganese, wolfram, and many others. The quantities of each of these so far produced is of no commercial importance, and in many instances is quite negligible. During December, however, a commencement was made with the opening up of enormous bodies of coal at the Powlett river in South Gippsland, the Government having resolved to work pits for the supply of its own railways, while private companies have been stirred to greater activity through the occurrence of a strike at the New South Wales mines, whence Victoria's supply has hitherto been mainly derived. At the Powlett river it is estimated that there are 25,000,000 tons of coal available and already five shafts have been opened and railway communication is being established.

NEW YORK.

Anaconda Charter Amendments.—Utah-Nevada Con. Aftermath. —Cobalt and Porcupine Lake.—Sonora.

It has been supposed that the new Anaconda Copper Co., which is to absorb the various Amalgamated properties at Butte, was to be an owning and operating company, doing away entirely with the corporate machinery of a holding concern. It appears, however, from the call, which has just been issued for the special meeting to be held on March 23, that the Anaconda is to become a full-fledged holding company. The call adds "that a committee has been appointed by the board of directors to confer with similar committees representing the respective companies interested, for the purpose of entering into negotiations for the purchase of the different properties involved, provided the necessary increase of stock is authorized, and that these committees and a non-interested board will endeavor to arrive by careful investigation at the fair value of all the properties which it proposed to purchase." Apex troubles seem to be much in the minds of the Anaconda officials, as a mine map of Butte is enclosed with the call, and this comment added: "The manner in which the mining claims of the different companies interested are interlaced, and the controversies which may arise in determining the ownership of underground orebodies apexing within the surface lines of the claims exhibited upon the map can be readily appreciated." The two individuals who 'appreciated' this situation most are no longer factors in Butte. Henry H. Rogers is dead, and F. Augustus Heinze, the original 'appreciator', is at present a rather discredited financier and no longer a thorn in the side of the Amalgamated Copper Co. B. B. Thayer, president of the Anaconda, has gone to Butte to arrange for the necessary examinations. The position of North Butte still remains very much a mystery. It is said on one hand that the property is to be left out of the Anaconda merger entirely, on account of the claim made against it by the Tuolumne. Contrariwise, it is said that the North Butte and Tuolumne will both be taken in and the matter in dispute between the two companies settled. As the ore which the Tuolumne claims is appraised by the Tuolumne at $8,000,000, it is apparent that some adjustment would have to be made before either concern could be absorbed. Many theories have been propounded as to why the larger copper merger was postponed after having been semi-officially announced as all but completed. Undoubtedly the main reason was the multitude of dedetails and the bitter disagreements provoked in getting together the preliminary consolidations. Mr. Morgan has sailed away for Italy, evidently with the intention of forgetting the whole matter for a time. The turn taken by the argument arising over the Utah Copper-Nevada Consolidated deal could hardly have been encouraging to Mr. Morgan and his associates, who were to stand sponsor for the greater merger. The Nevada Con. interests claim to have defeated the Guggenheims in their campaign for control of the company, and for the present both have ceased hostilities. It is anticipated, however, that there will be some litigation brought by the Nevada Con. stockholders, who are demanding the return of the stock which they deposited, the claim being made now that they were not fully informed as to the terms and conditions of the proposed exchange. There is a rumor that J. H. Hammond is to resign from the Utah board on account of the efforts which have been made to force through the merger against the apparent wish of a large number of the Nevada Con. stockholders. Mr. Hammond is at present absent from New York, and it is impossible to secure a denial or a confirmation of the story. It is anticipated that the Utah Consolidated will pass its next dividend; this is expected to be only temporary. After April 1 Utah Con. ores will go to the International S. & R. Co., which is controlled by Utah Con. interests, and the company will probably enjoy a lower smelting charge.

At the Goldfield Consolidated meeting held in New York this week the regular 30c. dividend was declared with an extra 20. The report that copper was coming into the ore on the lower levels was not accompanied by any selling orders from the West. On the contrary, it is apparent here that there were orders from the West to pick up any shares the news might bring out. It is hoped that the board of directors will clear the air of all uncertainty by making some definite announcement at the meeting. The Timmins Brothers, who first worked the La Rose mine at Cobalt, have taken an option on the McMahon-Hollinger property at Porcupine, the new gold camp to the north of Cobalt. The claims are said to have a fabulously rich surface showing. The discovery hole has been sunk to a depth of 30 ft., at present the deepest in Porcupine. The whole camp is now deep under the snow, but there has been quite a little trading in the properties 'sight unseen'. Canada made good with its silver camp, but was not able to hold the interest of the people of the States. Perhaps she can arouse some excitement with a gold camp. Montreal men interested in La Rose are credited with having purchased all of the holdings of the New York men in the company. From the January shipments the Cobalt output appears to be falling off, tonnage for that month being 400 tons below that of January 1909. Enlargement of concentrating facilities is given as a reason for the decrease. Both smelter and freight charges are saved by concentrating, and the result is a smaller tonnage of higher-grade ore. Charles S. Herzig and W. Murdoch Wiley are directors of and are interested in a new company formed to develop two sections of mineral ground in the neighborhood of the Little Lake properties in Ontonagon county, Michigan. The ground lies about eight miles from that of the Indiana Copper Co., which is being developed to catch the extension of the amygdaloid bed now being worked by the Lake Copper Co. The new company has a capital of $2,500,000 in shares of par value of $25. Several thousand shares are to be sold at $8 per share for development purposes. The Mines Company of America, operating the Creston-Colorado properties, near Minas Prietas in Sonora, Mexico, states in its annual report that there is as much ore in sight now as there was a year ago.

General Mining News.

ALASKA.

(Special Correspondence).—The Mount Andrew mine, in the Ketchikan district, has another large shipment of ore in the bunkers at Kasaan bay.——The It and Goodroe properties are preparing to commence operations March 1 after having been closed down for the winter.——H. S. Martin, manager for the Springfield Mining Co., is developing a galena property on Dall island.——M. M. Churchill reports good showings on the Tongas mine.——M. D. Ickis and W. L. Polson are sinking a shaft on their property near McLeans Arm. At present they have 8 ft. of shipping ore in their drift at a depth of 20 ft.——J. T. Jones has purchased a stibnite property on Cleveland peninsula, some of the ore assays over 50% antimony.——Most of the ore from this district is shipped to the Tyee smelter.

Ketchikan, February 10.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—D. T. Swatling and A. Y. Smith, who have had the Commonwealth mine and mill leased during the last six years, have purchased 75% of the stock, and are now operating the property under the name of the Commonwealth Mining & Milling Co. The mine is at Pearce, on the branch of the Southern Pacific railroad from Cochise to Gleeson. The vein strikes east and west cutting at right angles an andesite hill that rises abruptly from the smooth surface of White Sulphur Springs valley. The shoot is 60 ft. wide and 400 ft. long, and is opened by a 536-ft. incline shaft in the foot-wall, the incline corresponding to the dip of the vein. A new incline has been sunk on a smaller vein south of the principal lode. This dips in the opposite direction, and at a depth of 257 ft. it is found to join the main vein. The ore is four feet wide, and assays 12 oz. silver with $1 to $1.50 gold per ton. At the 150-ft. station drifts were run 60 ft. east and 36 ft. west in that grade of ore. In the last six years the lessees cyanided 400,000 tons of tailing that had accumulated as the result of previous operations of the 80-stamp pan-amalgamation mill. Part of this tailing was cyanided after dry-crushing. The mill is now being remodeled to provide for stamp-crushing in cyanide solution and all-slime treatment. The equipment, nearly all of which is installed, consists of 20 stamps, four sets of rolls, two Chalmers & Williams tube-mills, 20 ft. long by 4 ft. diam.; four Pachuca slime tanks, 12 by 36 ft.; two Burt revolving filters, each 30 ft. long, 5 ft. diam., which will treat 80 tons of slime per 24 hours. With this equipment it is proposed to handle 100 tons of ore per day from the mine, and 200 tons of tailing from a dump of 40,000 tons from the old mill. The two classes of pulp are to be united in the tube-mill. The tailing to be cyanided is moved in cars up an incline, dumped into bins, and drawn from the latter to a Jenisch ball-mill, wherein it is pulverized in cyanide solution. It goes then to cone classifiers, the slime passing to the Pachuca tanks and the sand to tube-mills. It is estimated that the crude ore thus treated will assay 8 oz. silver and $1.50 gold per ton, the cost of mining and milling same $2.50 per ton; that the tailing dump to be treated in this connection contains 4 oz. silver and $1 gold per ton, which can be treated at a cost of $1 to $1.25 per ton. It is proposed, ultimately, to re-treat the 400,000-ton dump which is supposed to contain 3 oz. silver and 50c. gold per ton. It is estimated that the cyanide consumption will be 1 lb. per ton of crude ore, and 0.75 lb. per ton of tailing treated. Steam-power is used, with oil as fuel at a cost at the plant of $1.94 per bbl. Edwin Burt, of El Oro, Mexico, patentee of the Burt filter, is expected here next month to inspect the work of these filters, as they are said to be the first installed in the United States.——L. R. Le Gier and associates, of Los Angeles, are opening a marble quarry in the Dragoon mountains, eight miles west from Pearce. There are 20 claims located and the marble found there is reported to be of excellent quality. A force of 15 to 20 men is employed there.——The Cochise Gold Mining & Milling Co., the control of which is held by P. W. Corcoran, J. E. McGee and Merrill Brothers, has a promising gold-bearing vein on a contact of porphyry and quartzite, three miles northwest from Cochise station. There is about 140 ft. of development work on the vein exposing gold ore, assays of which run from $4 to $25 per ton. The gangue is porphyritic and the gold is free. There are 12 claims in the group, covering the outcrop for over a mile. A gasoline hoist, probably, will be installed, and a deeper shaft sunk.

Cochise, February 19.

GILA COUNTY.

(Special Correspondence).—The directors of the Globe Mining Co., controlling the Mineral Farm property in the Copper Hill district, about four miles northeast of Globe, met in Chicago February 10 and voted to raise $100,000 to expend in development work. Meanwhile operations on the vertical shaft have been suspended.——The Williams shaft of the National Mining Exploration property, at its present depth of 568 ft., is in quartzite with considerable hematite stain. Occasional bunches of copper carbonate are also found.——For the present, the Superior & Boston Copper Co. will ship 50 tons per day of 9% copper ore to the Arizona-Commercial smelter. The sinking of the McGaw shaft which was resumed February 15, has advanced to a point 45 ft. below the sixth level. The shaft sump and the station-pump sump on the sixth level have been completed. By a method of stoping without the use of timbers, which the Superior & Boston Copper Co. has just adopted, it is expected that the cost of ore extraction will be lessened fully $1 per ton.——Three pumps are raising about 3,000,000 gallons of water per day from the Arizona-Commercial mine. The cross-cut northeast from the Eureka shaft on the seventh level has not yet cut the Black Hawk lode. The smelter is treating from 200 to 220 tons of ore per day.——The management of the Inspiration company is preparing to install a small testing plant to determine the ratio of concentration possible for the Inspiration ore.

Globe, February 19.

GRAHAM COUNTY.

(Special Correspondence).—The Cobre Grande group of 14 claims, 23 miles west of Fort Thomas, in the Santa Teresa mountains, has been sold by the locators to Albert F. S. Cooper, representing Wheeler & Shaw, brokers, of Boston. The purchase price is $100,000, to be distributed in semi-annual payments over a period of two years. This property is situated in the Aravaipa mining district. Operations to explore a 42-ft. vein of sulphide copper ore will be commenced at once and a development company will probably be organized within six months.——A sub-lease on the Comstock No. 1, 2, and 3 claims in the Clifton-Morenci district, has been granted to P. Weurschmidt who has interested El Paso capitalists in the property.——Work was recently resumed in the 1500-ft. adit at the Stevens group and a small vein of rich copper-silver ore has been opened.

Clifton, February 18.

MOHAVE COUNTY.

Up to the present time but little progress has been made in draining the Tennessee mine, which has been the centre of interest in the county since its purchase by the Needles Mining & Smelting Co. six weeks ago. Both a pump and a skip have been worked almost continuously since that time, but because of drainage waters getting into the old stopes, some of which had been worked nearly to the surface, and also considerable caving in the shaft, only about 100 ft. of the entire 600 ft. of shaft are clear. The Tennessee ores, sulphides of lead, zinc, and iron, are especially desirable as flux on account of the excess of iron, and will furnish the bulk of that metal for the company's enlarged smelter at Needles.——In the Midnight mine, which has been under bond to the White company, of Lima, Ohio, since December 1, four feet of low-grade sulphide ore containing copper, lead, zinc, and silver was cut on the east 200-ft. level. Daniel S. Richards is manager and Walter Fellows, superintendent.——M. A. Moore, superintendent of the Dixie Queen mine, in the Virginia district, returned from Indianapolis several days ago, where in a conference with the principal owners it was decided to erect a 5-stamp

mill. Mr. Moore left for Los Angeles to buy a mill and a 40-hp. hoist. While East he ordered a 3-ton automobile truck to be used for the 20-mile haul from Chloride.——At the C. O. D. mine, at Cerbat, whose record as a shipper is exceeded in this county only by the Gold Road, preparations are in full swing for the resumption of mining and milling. ——On the Silver Legend prospect, near the C. O. D. mine, W. D. Grannis has opened two feet of lead-silver ore, which assays 47% lead and 110 oz. silver per ton.——The new Tom Reed mill, at Oatman, was started a few days ago. Only 10 stamps are in operation, but it is expected that another 10 will be ready in a few weeks. Both mine and mill are operated by electric power from the Kingman plant.——At a depth of 100 ft. there was found in the main shaft of the Nil Desperandum No. 2 three feet of ore averaging $20 gold per ton. The mine adjoins the Pioneer property and is under management of H. E. Woods, of Los Angeles.

PIMA COUNTY.

At the old Pueblo mine, four miles west of Tucson, the shaft is now down over 300 ft. The property is being operated under a bond by an Eastern company, one of the conditions being that the shaft be sunk to the 500-ft. point. ——The shaft at the Chesterfield property has cut a number of rich stringers of lead-silver ore with small amounts of gold and copper at a depth of 390 ft.——A serious cave occurred in the shaft on the Villaescusa property in the Babaquivari mountains while it was being unwatered, and the work has been temporarily abandoned. An adit has been started lower down the hill that will eventually drain the shaft.

SANTA CRUZ COUNTY.

A rich discovery of zinc ore has been made at the old Flux mine near Patagonia. The property, which is owned by R. R. Richardson and associates, has been worked for the past twenty years for its lead-silver ore.

YAVAPAI COUNTY.

(Special Correspondence).—There are 50 men employed in Copper Creek district, 27 miles south of Mayer, where the Arizona Copper Queen and several other companies are developing. The former, in charge of W. B. Douglas, has a 200-ft. shaft and three or four others about 100 ft. deep. There is a series of radial veins in granite, the ore being a copper and silver-bearing quartz, mostly oxidized as far as opened.——The American Copper & Gold Co., owning the Iron King, close to Humboldt, may resume operations after the Humboldt smelter blows in. This is a gold and silver property, having lenses of ore in chloritic schist. The ore contains an excess of iron. S. R. Trengove, superintendent, states that the mine, when in operation, can supply 50 tons of ore per day.——There is considerable activity on the Cherry Creek district, 15 miles east of Cherry station. This camp is at the southern end of the Black Hills range, where there is a granite country, cut by porphyry dikes. The Arizona Copper Gold Mines Co. has locations covering what is known as the Leghorn vein, on which a 500-ft. shaft has been sunk. The vein is 2½ ft. wide, containing gold, silver, and lead, partly free-milling and the rest suitable for concentrating. A Lane slow-speed mill, 40 tons capacity, has been installed. J. S. Sessions, superintendent, states that he has operated the mill at a greater capacity and is well satisfied with the work. Besides amalgamating plates, he has installed a Woodbury table and a Frue vanner. The concentrate is to be shipped to one of the smelters in this district.——The Black Hawk group, in the same locality, is being considerably developed, and a steam-boiler, hoist, and Huntington mill are being installed. This belongs to the Federal Mining & Milling Co., in which C. C. Scoullar, of Chicago, and E. A. Bonham, of Cherry, are interested. J. H. Tribby has partly developed the Hillside property, in the same camp, and has put up a mill containing three Nissen stamps.

Cherry, February 18.

CALIFORNIA.

CALAVERAS COUNTY.

The Ball Mountain Mining Co. has purchased the Ball Mountain property, near Vallicita, and is installing a Dow pump and 12 by 12 in. compressor. The group is five miles from Angels Camp and adjoins the famous Bishop mine on the Vallicita channel. F. Saville-Smith is consulting engineer.——A 100-ton mill and steel head-frame are to be erected at the Boston mine in the Mokelumne Hill district in the near future. The lumber has been ordered and the roads to the mine are being repaired.——The adit at the Ariel Consolidated Mines property, which is under bond to J. L. Green and associates, of San Francisco, is in 400 ft. A drift has just been started on the vein and is opening some fair copper ore.

INYO COUNTY.

The Benton Mining Co. has sold $100,000 worth of bonds and has purchased a compressor and power-drills. The company is operating a group of claims on Blind Spring hill, near Benton, and is to start an adit near the base of the hill that will tap the old Cornucopia and Commanche veins. C. E. Julihn is in charge of the work.——The Four Metals company is shipping, approximately, 10 tons of ore per day. The company's smelter has been closed temporarily and in the meantime the ore is being shipped to Utah. ——A rich 8-in. stringer has been opened in the North Inyo mine, six miles east of Bishop, and the ore is being sacked for shipment.

LOS ANGELES COUNTY.

At the annual election of the Los Angeles Chamber of Mines, Calvert Wilson was elected president; S. E. Vermilyea, first vice-president; J. S. Mitchell, second vice-president, and J. R. Mathews, treasurer. The annual meeting of the Chamber was held February 18.

MARIPOSA COUNTY.

Several men have been laid off at the Mount Gaines mine, in the Mariposa district, while the shaft is being sunk another 100 ft.——There is a large force at work at the Ruth Pierce and some good ore is being opened.——Petitions have been filed for the sale of the Diltz property, and the group belonging to the Teats estate.

NEVADA COUNTY.

Operations are to be resumed at the Banner Ridge drift mine, near Nevada City. The shaft is down 120 ft., and it is believed that it will cut the gravel within the next 50 ft. C. A. Bailey is manager.——A contract has been let by A. L. Shinn, of Sacramento, and C. L. Wilson, of Lincoln, for the erection of a 25-stamp mill near the Sierra county line. The work will be started as soon as the roads are in good condition for hauling and the plant will treat the ores from the Black Bear and Metropolitan mines.

PLACER COUNTY.

A number of the smaller mines at Ophir are crushing their ores at the Malmberg mill which has been idle for several months.——The adit on the property of Charley Glover is now in 550 ft. The 5-stamp mill is crushing ore that assays from $15 to $20 per ton.——A telephone line is being strung from the Rawhide mine to Alta and a road to Towle will be constructed this spring. The main adit is in 1400 ft., and two others have been started.——At the Herman mine the shaft is down 80 ft. from the adit level and a station is to be cut at this point. The mill is running on good ore.——The Hibbe copper prospect has been sold to an Oakland company and the shaft unwatered.

SHASTA COUNTY.

(Special Correspondence).—At Iron Mountain the Mountain Copper Co., Ltd., is pushing work steadily on its 3-compartment shaft which will be continued to the 500-ft. point to tap the ore at depth. A good body of fluxing ore, assaying well in gold and silver, is being opened. Structural material is arriving regularly and it is understood that operations will be resumed at the Keswick plant some time this summer.——A call has been issued for a meeting of the stockholders of the Inca Treasure Co. and the Delta Con. Gold Mining Co. in order to adjust the difficulties involving the corporations.——Operations at the Heroult electric iron smelter continues satisfactory. H. H. Noble, the manager, states that the capacity of the plant will be increased if production continues satisfactory.——A bond has been taken on the Jim Loage group by Eastern interests.——Op-

erations have been resumed at the Milkmaid, after a brief shut-down compelled by the recent severe storms.——At the Gladstone work is being carried forward on the vein opened some time ago on the 800-ft. level. The mill is producing at the rate of $40,000 per month.——The Consolidated Dredger Co. is moving its dredge from Clear creek to Middle creek. ——The United States Dredging Co. is re-constructing its dredge on Middle creek. The old hull was demolished last summer.——Operations have been resumed at the Mad Ox. ——Canadian business men have taken a bond on the Mad Mule group. The 165-ft. adit will be driven 200 ft. farther to open the vein. A. Egerton is superintendent.

Redding, February 19.

SIERRA COUNTY.

(Special Correspondence).—A deposit of bonanza quartz has been found in the main adit of the Rainbow Extension mine. Developments have not progressed sufficiently to prove the extent of the vein. O. A. Harlan, of San Jose, is manager.——A raise for air has been completed at the Rainbow and the development of the property is progressing steadily. The mill is running day and night. W. M. Wilson is superintendent.——A body of rich gravel has been opened in the Omega at a point 1300 ft. from the portal of the adit. On account of the roads, which prevents the shipment of necessary supplies, but little work is being done and the mill is idle.——The Plumbago is producing steadily.——The Wild Joe, recently bonded by C. L. Crane and associates, will be actively worked this spring. The vein is 5 ft. wide, and occurs in a slate formation. Assays of $10 to $31 per ton in gold have been obtained. The ore is generally free-milling.——The new company controlling the Sixteen-to-One expects to resume activities within a few weeks. Arrangements have been made to start a large force of men.

Alleghany, February 19.

A new adit at the Slate-Castle Jaffa property in the Downieville district has been started 100 ft. below the upper workings. There are five men now working on the property but the force will be increased as soon as the weather modifies.——Jason Frye has purchased the interest of Thomas E. Winrod in their lease on the Standard mine in Sailor ravine. The Standard has produced some of the richest arsenical sulphide ore found in the district. ——A small vein of high-grade ore has been opened at the Morning Glory mine, in the Alleghany district.

TRINITY COUNTY.

(Special Correspondence).—The Forest Service, together with the county, is building a new trail along the Trinity river that will open a large amount of placer ground in the districts tributary to Weaverville. Lack of transportation has been a serious handicap to this portion of the country. ——At Cox bar, Tinsley & Trelom have opened a gravel bar formerly known as the Tom Price drift mine. The original owners of this property took out considerable gold by drifting and the mine was considered worked out. The present operators secured the ground for a nominal sum and fitted up a small hydraulic plant obtaining about a 70-ft. head. The two first clean-ups netted the operators $100 for each hour the water had been turned against the gravel. The extent of the rich ground has not been determined as it is thought that a portion of it had been enriched from a higher channel which was worked several miles down the river at the Highland mine. Down the river from Cox bar a number of small mines are operating on pay-gravel.——At Don Juan point F. Murphy is operating a giant on some good ground.——From Don Juan point to Hawkin's bar there are several large areas of gravel comparatively untouched while in the neighborhood of Hawkin's bar a number of hydraulic properties are doing well. From Hawkin's bar up the Trinity river for 40 miles there is a large amount of excellent gravel.——The Headlight mine, at Carrville, is to spend $150,000 this spring in the erection of a 40-stamp mill and 400-hp. hydro-electric plant.

Weaverville, February 21.

TUOLUMNE COUNTY.

(Special Correspondence).—The Erie Mining Co. last week paid off all indebtedness for labor, and it is reported that operations will be resumed soon. The water ditch, which is about two miles long, is being cleaned.——The mill at the Black Oak, after a thorough overhauling, started Thursday of last week on good ore. The property is at present giving employment to 30 men.——A 5-stamp mill is being erected at the Maddox mine, situated one mile east of Confidence and operated by the Phoenix Lake Mining Co. Underground work is carried on with a small crew of men. ——The hoisting machinery on the Springfield Tunnel & Development Co.'s property is being moved to the Hard Rock incline shaft, where a new building has been erected. ——The Draper mill has again been put in operation after a shut-down of several weeks, during which it was thoroughly overhauled.——A restraining dam is being constructed at the Red Gravel mine, at Yankee Hill.——The wagon-road leading to the Ethel mine is being regraded to lessen the difficulty of transporting supplies to the property. The mine is being actively worked and the mill is running steadily.——The Densmore Mining Co. has acquired, by deed, a claim adjoining the Densmore mine which was owned by A. J. Miller.——At the Laguira mine, near Groveland, recently bonded to Thomas Lane, of Angels Camp, preparatory work has been commenced.——Another rich find was made a few days ago in the Gold Spring mine, which is to be equipped in the near future with a 10-stamp mill.——According to information being given to miners applying at the Confidence for employment, underground work will be resumed about April 1. Fifteen stamps are being used to crush the ore from the dump, which is said to be giving satisfactory results.——A 2-stamp mill is being installed at the Doneill mine, which is being operated by George E. Brown and associates.——In addition to making other preparations for commencing actual mining operations at the Little Gap gravel property, a large concrete dam will be constructed. The property, which is situated above Groveland, was a short time ago bonded by George Hamilton to a company composed of Stockton people. Lumber, tools, and supplies are being taken to the property, and with a small crew of men the preliminary work is now well under way.

Tuolumne, February 21.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Kelly Adit property on Democrat mountain, in the Georgetown district, is to be taken under bond and lease by B. F. Kelly, representing a syndicate of Colorado and Eastern capitalists and work will be put under way by March 1. The Kelly adit has been driven for 2800 ft. and is just penetrating the richest portion of the hill. The property is equipped with compressor plant and 50-ton concentrating mill.——In a few days electric power will be turned on at the holdings of the Accord Mining & Milling Co., on Saxon mountain, and the adit driven ahead with power-drills.——The Argentine Central Railway Co. has started work in the opening of the ground of the Santiago vein which was recently secured under lease and operations are being carried on through the Wilcox adit. C. L. Tingle is in charge.——A force of 50 men is now at work in the Stanley mine, in the Idaho Springs district. The water has been lowered to the fourth level, while large development is being carried forward on levels 1, 2, and 3. Seven sets of lessees are at work with machine-drills and during the past week the 50-ton mill was started. J. E. Bowden is operating the mine under lease.——A lateral is being driven from the Central adit to intersect the Refugee vein which was recently secured under lease by Hunt & Deming, of Denver. This vein is the west extension of the Shafter, and has a large production record.——Barnes Brothers, operating a group of claims on Santa Fe mountain, sent out a carload shipment of ore last week to the Modern smelter. A return of $32 per ton gold and silver was realized.——Thomas Hennehan, of Silverton, has been appointed manager of the Chesapeake mine at Alice and is opening the workings preparatory to starting shipments.

Idaho Springs, February 19.

GILPIN COUNTY.

(Special Correspondence).—A streak of smelting ore 14 in. wide has just been uncovered on the Great Bonanza

property, near Central City, at the 560-ft. level of the shaft workings that assays $60 per ton in gold. Cecil Morgan is manager.——A gold 'retort' weighing 88 oz. was sold this week by H. Lowe, manager of the Topeka property, for $1400.——Work has been resumed on the Grand Central property by McMasters Brothers. The machinery is being overhauled and the compressor plant will be started during the next few days.——Work has been resumed at the Hilltop mine in the Russell district. A streak of ore has been found that is 8 in. wide and assays 1.16 oz. gold with 80 oz. silver per ton. H. Ramstetter is manager.——The Bald Mountain Mining & Development Co., operating in the York district, has advanced its adit 325 ft. and it is expected that a vein will be intersected within a short distance.

Central City, February 19.

LAKE COUNTY.

From 25 to 30 tons of zinc ore is being shipped from the Yak tunnel at Leadville to the smelter at El Paso and it is understood that a number of Leadville producers are to ship their zinc ore to the El Paso plant this spring.——Regular shipments are being made from the La Plata mine, on Rock hill, after an idleness of several years. A large vein of 45% lead ore has been opened.——Otto Thurn and associates have driven a drift 600 ft. on the 400-ft. level of the Louise property, in South Evans gulch, and are making arrangements for more extensive development.——According to a lease recently entered into by the present lessees of the St. Louis tunnel the Big Four shaft on Breece hill is to be sunk over 250 ft. during the next two years. Work is to be started April 1 of the present year. Kendrick P. Crawford represents the lessees and a graduated scale of royalties is to govern the payment for all ore mined. The Big Four property adjoins the St. Louis tunnel holdings. The lessees of the latter property have met with almost unprecedented success during the past few months. In their operations they have discovered valuable gold-bearing ore and have made regular shipment from the vein. They have calculated that the same streak continues into the Big Four ground.

OURAY COUNTY.

Five feet of ore have been found in the Bright Diamond property in the Ouray district above the ore that the company has been mining in the past. A portion of the vein

Camp Bird Mill, Ouray County.

is free-milling and a portion will be shipped to the smelter. The company is planning on the erection of a mill and compressor-plant shortly.——The shaft at the Neodesha, under bond to John Keleher, cut a small vein of high-grade ore.——What is believed to be the Mendota vein has been cut in the Thistledown property. The machinery for the new mill is being put in place rapidly and work on the pipeline for the power-plant and tramway is going ahead as rapidly as the weather conditions will permit.

SAN MIGUEL COUNTY.

In the Favorite mine, at Ophir, a 3-ft. vein of lead-silver ore is being opened with good results. The ore broken in the development work is now being sacked for shipment to the smelter, netting the company, approximately, $1000 per carload. The mill has been thoroughly overhauled and an aerial tram is being built to connect the mine and mill. The ore readily concentrates from five to one, the product assaying 1.5 oz. gold, 14 oz. silver, and 25% lead. Besides this the ore plates about $3 gold per ton. Gus Carson is superintendent.

SUMMIT COUNTY.

The tunnel of the King Solomon Mining & Tunnel Co., at Frisco, is now in 3600 ft., and has cut 11 veins. Development work has been started on six of these and considerable good ore is now being opened.——Work has been resumed on the White Cloud property, in the Brekenridge district. A. A. Pike is superintendent.——A gasoline power-plant is being installed at the O'Reilly property, and in the future machine-drills will be used in driving the adit. A. C. Howard is manager.——The road has been broken to the Arctic mill, and work is being rushed in the construction of the mill.

TELLER COUNTY.

An 80-ton shipment from the Modoc mine, between Bull hill and Battle mountain, in the Cripple Creek district, has been forwarded to the Eller smelter at Pueblo. The ore was mined on the 900-ft. level and will average $40 per ton. F. H. Frankenberg, Sr., is manager.——Sampson & Truscott, who recently purchased the sub-lease on the Longfellow No. 2 of the Stratton estate, have opened a good shoot on the first level and are now shipping ore.——The drift on the 300-ft. level of the Pinnacle Gold Mining Co.'s property has opened a shoot of high-grade ore containing from ¼ to 1 in. sylvanite. The property is under lease to the Pinnacle Leasing Company.

MONTANA.

SILVERBOW COUNTY.

(Special Correspondence).—J. J. Harrington, secretary for the Tuolumne Copper Mining Co., is authority for the statement that during the month of January the company produced 728,000 lb. of copper containing silver valued at $5491. The Tuolumne company is well satisfied with the conditions at present prevailing, and it has no fear of any litigation arising from a question of dispute with the North Butte.——An application has been made for the appointment of a receiver for the Hypocka Mining Co., a Heinze concern organized a few years ago during the trouble with the Amalgamated. A judgment was secured against the company for $14,000, but the sheriff reports that he is unable to find any property to levy against. An application has also been made for a receiver for the Pittsburg & Montana Copper Co. in consequence of the failure of the company to pay a judgment for $18,000 and on the strength of the sheriff reporting that he was unable to find any property to satisfy the judgment. The Pittsburg company is capitalized at $30,000,000, while the Hypocka company is capitalized at $100,000. The attorneys who represent these companies have refused to accept service on the ground that they no longer represent them. As both companies are liable to the full amount of their capital stock the attorney who made both applications for the receivership declares that as soon as the receivers are appointed he will see that the full amount of the judgments with interest will be collected from the stockholders.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—The controversy recently precipitated as the result of assertions that the gold content of the ore was being replaced by copper as depth is attained in the Consolidated mines, at Goldfield, has been given an effective quietus by a statement issued by the general manager, J. R. Finlay. Copper in small quantity is found throughout the Goldfield district and occasionally small seams or pockets of rich copper ore have appeared, but in no greater frequency at depth than near the surface, and at only a few scattered points has the quantity been other

than negligible. In point of fact there is less copper known to exist in the mines of the Consolidated than in the Florence, C. O. D., or Daisy. Development in the Consolidated mines continues to add to the ore reserves, particularly in the new workings of the Clermont where the vein is being opened for great width at the 750 and 900-ft. levels. The 1000-ft. level is being driven in vein-matter and from the highly silicified character of the material, it is expected that the ore-shoot will be penetrated within a short distance from the present face. The tonnage treated by the mill has exceeded 850 tons per day, a large part of this product coming from the Clermont shaft which is now capable of producing over 600 tons per day. The recently burned machine and carpenter shops at the mill are being replaced by more complete buildings and equipment. Additional provision has been made for fire protection both at the mill and near the surface plants of the mines. There is little danger of fire at any time in the mine workings. ——Timber sets for the enlarged Florence shaft are now being prepared and the work of opening the third compartment from the 500-ft. level to the surface will soon be in progress. This shaft, of small size, was first sunk to the 350-ft. level, and last year was completed to the 500-ft. point by raising from a cross-cut driven at this depth from the Engineer's shaft. Little work has been done in ground adjacent to the main shaft below the 350-ft. level, but laterals have connected this shaft with many of the old lease workings. A drift to the north has reached the Reilly lease territory and in its course has exposed good milling ore for 500 ft. The attention of the management has been devoted, largely, to the ground to the south embraced by the Little-Florence and Rogers leases where ore is being broken and blocked out in readiness to supply the mill through the Little-Florence shaft and over the aerial tramway while the main shaft is being enlarged.——At both the 200 and 300-ft. levels of the Gold Bar workings recent development has been attended by most encouraging results, insuring a profitable product for the lessees, W. F. Gray and associates, who have secured a five-year lease on the claim and will erect a 50-ton mill. Sample shipments of the ore have been sent to Denver with which to conduct tests to determine the best process of treatment and ore is being prepared for shipment to the smelter. A 4-ft. vein of excellent milling ore is exposed in which there are seams of richer material showing free gold.——Development will soon be in progress from a station at the 800-ft. level of the Combination Fraction to which depth the shaft has been sunk lately from the 600.——In the Annex shaft on the Polverde, a station has been cut at the 800-ft. level, just below the point where the vein contained 4 ft. of ore averaging $50 per ton. The second drum of the hoist has been wound with cable, and guides are in place for the second cage in the double-compartment shaft, which will be continued to a depth of at least 1000 ft. in the expectation of cutting the Clermont vein. Driving will be begun at once on the vein. Ore-bins are being installed, a spur built to the dump from the railroad, and a compressor will be used to operate the machine-drills. Preparations are being made to begin shipping ore at once. This vein apparently trends directly toward the St. Ives and Velvet claims of the Goldfield Merger Mines Co. to the east and south.——Ore is now being broken at the 350-ft. level of the St. Ives by lessees. The Merger company's main shaft is 600 ft. deep and the prospects of finding the Annex vein from this shaft are said to be excellent. A new lease on the Booth includes the company shaft from which a cross-cut is being driven toward the Red Top vein at 260-ft. depth. From the Banner shaft on the Booth a cross-cut has been driven to the vein and small assays obtained.——Pay-ore has been opened by lessees within the past few days on both the Blue Bull and Commonwealth. The extent of the ore-shoots is still problematical.——The Grizzly Bear shaft, sinking at the rate of 5 ft. per day, is nearing the 1000-ft. level and will be continued to cut the hanging wall of the Mohawk vein, which it is expected to penetrate near that depth.

Goldfield, February 19.

LANDER COUNTY.

(Special Correspondence).—The Nevada-Omaha Mining & Milling Co. has arranged to sink a 200-ft. shaft on its properties at Bannock, and a steam-hoist has been ordered. The drift from the adit on block 2 has opened 28 ft. of $9 ore and the lessees on block 9 have intersected 3 ft. of ore assaying $40 to $60 per ton.——The Nebraska-Bannock has started work on a 50-ft. shaft to open a 2-ft. vein that assays $6 per ton on the surface.——The Phfladelphia-Western, Hilltop, and Golden Rule properties have been acquired by M. C. Scully and associates of Illinois and Canada. A 20-stamp mill will be immediately installed. The owners have been shipping high-grade ore for several months.——The Horton company has practically completed its 20-stamp mill and will commence crushing ore soon. A large quantity of ore assaying $20 to $30 per ton is reported opened in the property.——The Golden Hub Leasing Co. is driving a 300-ft. adit to open the vein between the granite and quartzite on the north half of the Big Five claim. A 10-in. seam of oxidized quartz has been cut.——The Hanks lease on the Pioneer and Smuggler lodes of the Buzzard is developing a vein of copper-silver-gold ore.——It is expected that the first unit of the Austin-Manhattan 10-stamp mill will be in operation in June. The Frost shaft is down to the 900-ft. point and a cross-cut will be driven north from this point to open the Panamint and Independence veins.

Battle Mountain, February 17.

WHITE PINE COUNTY.

(Special Correspondence).—It is reported that Ely Centennial has penetrated 15 ft. of ore at a point 52 ft. below surface.——North and south drifts are being driven from the 400-ft. level of the Zack shaft on Ely Consolidated. The vein recently opened at this point has been cut for 20 ft., the ore assaying from 3 to 4% copper. The raise from the 400-ft. level of the Brilliant shaft workings is up 50 ft., exposing 18 in. of ore assaying 10% copper and $15 gold and silver.——The McDonald Ely has resumed operations.

Ely, February 19.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—A dividend of 2%, the first for some years, has been paid by the North Star mine in East Kootenay. There is considerable ore in sight, the last car of which gave a smelter return of 70 oz. silver and 60% lead.——The Canadian Northern Railway Co. has acquired the Dunsmuir coal interests on the coast for $11,000,000. It is reported that J. P. Morgan & Co. are financing the enterprise and that five or six million dollars more is to be expended, a steel and iron works being planned.——At the annual meeting of the British Columbia Copper Co., held last week at Charleston, West Virginia, the figures for the year ended November 30 showed that the company had earned 10% on its capital stock, despite a forced period of idleness during the fiscal year reviewed. ——The Copeland Mining & Development Co. has arranged for a two-year extension of its bond on the Le Roi property. ——A 9-ft. galena vein has been struck on the Silver Cup property, near Hazleton, recently bonded by Rossland men to Prince Rupert, capitalists, for $40,000.

Rossland, February 19.

MEXICO.

CHIHUAHUA.

(Special Correspondence).—The Alfarena Mining Co. has been organized to take over the Alfarene mine in the Santa Barbara district, and is testing the ore to determine the best method of treatment. F. C. Morehouse is at the head of the new company.——On a gross production of $807,783 in 1909 the San Toy Mining Co., operating in the Santa Eulalia district, netted $326,483. A deficit of $164,582 was carried forward from 1908.——The Guggenheim interests are negotiating for the purchase of the properties of the Chihuahua Mining Co. and the Potosí Mining Co. in the Santa Eulalia district.——The Joquivo Development Co., controlled by Charles and J. S. Qualey, will build a 100-ton mill and cyanide plant at Joquivo in March or April. The company is opening a gold-silver property.

Santa Eulalia, February 18.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. S. Noyes has gone to Oregon.

J. V. N. Dora is in San Francisco.

A. D. Foote was in San Francisco this week.

W. Spencer Hutchinson has been at Los Angeles recently.

J. Morgan Clements has gone to Los Angeles.

Fred T. Williams has been examining mines at Park City, Utah.

E. C. Vigeon is manager for the United Rhodesia Gold Fields, Ltd.

H. J. Sheafe was down to San Francisco from El Dorado county this week.

C. E. Morris has left London for the Santa Francisca mine, Nicaragua.

E. H. De Vore, mining engineer, has opened an office at Douglas, Arizona.

W. O. North is now at Goebilt, Sarawak, Borneo, instead of New York as formerly.

E. A. H. Tays has returned to San Blas, Sinaloa, from the central plateau of Mexico.

Gerald M. Browne is in Venezuela on a visit to the property of the Rio del Oro, Ltd.

L. S. Austin has opened an office in the Dooly block, Salt Lake, Utah, for consulting work and mine examinations.

R. E. Miller married Miss Euretta Stevens at Denver recently and is at Hahn, Idaho, with the Lemhi Smelting Company.

George G. Vivian, formerly superintendent at the Tintic smelter, is now manager at the Golden, Colorado, plant of the North American Smelter & Mines Company.

Selwyn Goldstein, of Pearse, Kingston & Browne, has arrived at the Tominil mine (Mexico), which he is to manage. K. D. Armstrong will join him as mine accountant.

J. H. Wise has resigned from the Pacific Gas & Electric Co. to become a member of the firm of F. G. Baum & Co., hydro-electric and irrigation engineers, 1404-1408 Chronicle building, San Francisco.

Thomas Hoatson and Gordon R. Campbell, directors of the Calumet & Arizona Mining Co., with William Kemp, consulting engineer, have been visiting mines at Mammoth, Clifton, and Morenci, Arizona.

Lyman P. Hammond, recently sales manager for the Denver Engineering Works, and formerly with the Crocker-Wheeler Co., has taken the position of manager of the sales department of the Central Colorado Power Company.

P. G. Spilsbury, of New York, has associated himself with Spurr & Cox (Inc.), and will be identified with the metallurgical department of that firm of consulting engineers. His new address is Room 10, Chamber of Commerce building, El Paso, Texas, with Godfrey Doveton.

J. W. D. Moodie has opened an office in the Story building, Los Angeles, California, and will devote special attention to transportation projects. Until recently he has been chief engineer for the Guanajuato Development Co., and its allied interests, and was in charge of the building of the mining railroad for the Phelps, Dodge & Co., at Nacozari, Sonora.

The San Francisco Section of the Mining & Metallurgical Society of America met at the Palace Hotel, February 21. The following members and guests were present: A. B. Christie, Francis Drake, J. F. Newsom, F. W. Bradley, M. A. Folsom, Gelasio Caetani, Edgar A. Collins, George B. Starr, A. C. Lawson, Corey C. Brayton, J. Morgan Clements, E. B. Kirby, C. W. Merrill, H. F. Bain. Arrangements were made for an executive session March 21, and a general session April 21. At the latter 'Porphyry Coppers' will be discussed.

The Canadian Mining Institute will meet in annual session at Toronto, March 2 to 4 inclusive.

Goldfield Consolidated Operations in January.

The following tables and information are given out by J. R. Finlay as the official preliminary report of operations of the Goldfield Consolidated for January:

	Tonnage produced		
	Wet tons.	Dry tons.	Assay oz.
Combination	6,303	6,193	0.89
Mohawk	8,325	7,928	0.74
Red Top	6,555	6,243	1.76
Clermont	4,089	3,716	4.21
Totals	25,272	24,080	1.58

	Approximate value produced.	Per dry ton.
Combination	$114,093	$18.41
Mohawk	121,088	15.27
Red Top	227,122	36.36
Clermont	323,195	87.00
Totals	785,498	32.62
Loss in tailing	55,898	
Estimated recovery	729,600	

The values indicated as recovered were not all precipitated and turned into bullion at the end of the month. Owing to the increased tonnage treated in the mill there was a larger amount of concentrate in process at the end of the month than at the beginning. Mr. Hutchinson estimates that 60 tons of concentrate, containing 1000 oz. gold, belonging to the January ore, had not been treated.

EXPENSES.

		Amount.	Per dry ton.
General expense		$28,200	$1.18
Mining: Pay-roll and salary	$53,256		
Power	4,416		
Supplies	35,400		
Departments	7,972		
		101,044	4.21
Railroad		2,000	0.08
Milling: Pay-roll and salary	14,838		
Power	7,848		
Supplies	32,500		
Departments	2,603		
		57,789	2.41
Marketing concentrate		23,000	0.96
Total cost		$212,033	
Less miscellaneous earnings		1,713	
Net cost		$210,320	$8.73
Loss in tailing			2.32
Total costs and losses			11.05
Profit per ton			21.57
Total value of ore			32.62
Total profit per month			$519,300

It will naturally be of interest to note the effect of an increased tonnage on operating costs. In my telegram of January 31 I estimated the total expense at $197,000. This appears to be an underestimate to the extent of $13,000. This arises from the fact that the estimate was made simply on the total number of men employed, calculating $9.75 per shift. It appears now that the increased tonnage calls for a larger consumption of supplies in proportion to labor. The total sum of $13,000 can be accounted for in two items. First, an increase in supplies and labor at the mine of about $6000, and second, some additional expenses at the mill, caused by finishing construction which last month was charged to construction, but this month to operating, and also some supplies lost by fire and an additional consumption of chemicals and supplies due to the freeze-up and shortage of water in the early part of January. However, after making these corrections, it is still found that the total cost has come down a little, principally in the item of general expense. The cost of mining and development is a few cents lower than for December, and the cost of milling a few cents higher. On the whole, it is safe to say that the reduction in costs, due to a production of 25,000 tons per month, as against 20,000, will be almost entirely in the over-head charges. It is too early to figure on much reduction in other directions, but when the difficulties at the mill are fully overcome there should be some reduction there. As to mining, it is difficult to see much opportunity for lower costs; possibly somewhat higher costs should be anticipated on account of the necessity of providing equipment for operating at greater depth than heretofore.

Heretofore this company has published its complete costs only in the annual reports, but it has made a practice of publishing at intervals its operating costs, namely, mining, transportation and milling. In this statement, however, the effort is made to show the total deductions that must be made from the gross value of the ore, calculating gold at $20.67 per ounce, to arrive at net profits applicable to dividends. Very few companies issue such statements. The items that are stated as costs now that were not so stated formerly are the general expenses, of which at least half are bullion taxes and the cost of realization of bullion. Further, the cost of smelting residue from the concentrate plant is now included as an operating expense under the head of milling. The sum total of costs and losses will vary according to the grade of the ore. The bullion tax and tailing losses vary directly with the grade, and the cost of marketing concentrate residue varies also, but not in direct proportion to the value contained. This explanation is intended to dispel the surprise caused by a statement showing the total costs and losses instead of the direct operating costs. The former are about $11 per ton and the latter somewhat less than $7. It is, perhaps, worth while to state that the sum total of costs and losses is apparently less than that of any other gold mining company in the world that produces an ore of similar grade.

The total advance made in development headings is the largest on record, being as follows:

	Feet.
Combination	840
Mohawk	1020
Red Top	1328
Jumbo	1375
Total	4563

Of this development a total of 858 ft., or somewhat less than 20%, was in ore. Most of this work, however, was simply following orebodies that were already presumed to exist, and cannot be said to add anything to ore in sight. In the Combination and Mohawk no new ore was developed during the month. In the Clermont, on the 750-ft. level, developments were made in three new places exposing ore of a total area on that level of 1254 sq. ft. Of this amount 780 sq. ft. is due to the extension of the sill-floor in the large stope No. 401. Since no equivalent developments were made on the levels above and below, this ore should only be considered to extend half the distance to the 600-ft. level upward, and half the distance to the 900-ft. level downward. In other words, a reasonable estimate of ore put in sight by these developments should not be calculated on a vertical extent of more than 120 ft., but this will allow an estimate of approximately 12,000 tons put in sight at the Clermont as against 3700 tons extracted. The average grade of this ore is about $70 per ton. In the Red Top, out of a total of 217 ft. in ore only 96 ft. belongs to drifts on main levels putting new ore in sight. The total amount may be roughly calculated at 4000 tons of an average value of $15. In round numbers the developments of the month have put in sight 16,000 tons, with a total value of $900,000, as against 24,000 tons mined with a total value of $785,000, showing a surplus of value put in sight for the month, but a shortage of tonnage. On the 1000-ft. level of the Clermont, the main crosscut reached the vein, but thus far no ore has been encountered. The silicified mass in which the ore is expected is found with its usual attitude and appearance. Drifting is now in progress on a seam which will undoubtedly soon lead to an ore-shoot.

EDITORIAL.

THE CENSUS BUREAU and the Geological Survey will co-operate this year in the collection of mineral statistics. If this results in as notable reports as those based on the co-operative work of 1880, the volumes will be in large demand.

MINIMUM tariff rates will be applied to articles of commerce entering the United States from Mexico. The order for such privilege, as provided by the terms of the Payne-Aldrich tariff law, was recently signed by President Taft. No announcement of reciprocal concessions on the part of the Mexican Government has yet been made.

YERINGTON, the Nevada district discussed on another page by Mr. F. L. Ransome, is likely to see lively times this year. A railway has been built from Wabuska down to Mason Valley and is to be extended twenty miles to the south. Among other improvements planned for this season is a smelter to be built by the Nevada-Douglas and allied interests.

A DIVIDEND disbursement of $8 per share will be made by the Calumet & Hecla for the first quarter of 1910. This is at a considerably higher rate than for the same quarter of 1909. With this payment the total distribution to stockholders since the organization of the company will have been $112,150,000, placing the Calumet & Hecla above all rivals as the most successful mining company in the world, measured by the magnitude of its returns.

ILLINOIS is to have both mine rescue stations and miner's institutes. The recommendations to that effect made by the Mine Investigation Commission have been approved by the General Assembly and $75,000 appropriated for the first, with $25,000 for the second. This is an important move in the right direction. A recent court decision relative to methods of appropriating money in Illinois may delay these and other matters, but the ultimate outcome is no longer in doubt.

GRATIFYING news comes to hand of the declaration of a dividend by the Florence Goldfield Mining Company of ten cents per share, making an aggregate disbursement of $105,000. It is also pleasing to note the wisdom of the directors in declining to be swept by enthusiasm into the risky position of establishing a regular quarterly dividend of this amount. The policy of paying what profits warrant, and of creating an adequate reserve fund, leaves a mining company in a stronger position. The market price of the stock is no more likely to suffer extreme variations under such circumstances than when the payment of a fixed sum is pledged. To pass

a regular dividend is certain to produce alarm, though it may be done for the sake of preparing for an increase in earning power.

REVISION of the mining code of the Republic of Chile is in progress. This is being made in the first instance by a committee appointed by the Chilean National Society of Mines. After approval of the revised code by the directors of this Society it will be submitted to Congress. The latter body will probably enact the measure into law practically as it comes from the hands of this group of representative mining men, who are supposed to know best what legislation is needed to facilitate the mineral industry. The revision makes no changes in the fundamental law, but is directed toward the elimination of obscurities and defects recognized in the existing statute.

THE SENATE Committee on Mines and Mining, we are glad to know, is likely to amend the House bill for a Bureau of Mines, by raising the salary of the Commissioner to the sum originally proposed, $6000, and inserting a qualification clause to assure that a technical man be appointed. Another much needed amendment is one leaving the Commissioner free in the matter of payment of salaries. Let Congress determine each year the amount which can be spared for each branch of the work, but let the Commissioner pay out of such sums whatever is necessary to get the best man for each investigation. The West wants to get away from regulation and investigation by '$1200 a year' bureau clerks.

KANSAS has been supposed by many to be the peculiar home of cyclones and trouble. This is a prejudiced point of view. As a matter of fact the name of the prairie State is fast becoming a synonym for sane and substantial prosperity. Last week, just by way of emphasizing that the resources of the State are not wholly agricultural and literary, the University dedicated at Lawrence a group of buildings, one being devoted to engineering, the second being a mechanical laboratory and power plant, and the third serving for investigation and study of geology and mining. Mr. E. R. Buckley, in his new capacity as president of the American Mining Congress, delivered the dedication address at the mining building.

REPLYING to the criticisms of Mr. James Phillips, Jr., a letter has been issued by Mr. Charles M. MacNeill, president of the Utah Copper Company, in which the pot admonishes the kettle as to its color. The statement that the Utah company can count on more than 100,000,000 tons of proved ore reserves may be accepted, but past experience would suggest caution regarding the average copper content ascertained by drilling of so large a quantity. On a mass lying as steeply as does most of the Utah Copper Company's deposit, the difficulty of restricting steam-shovel mining to the 'commercial ore', keeping out portions of the overburden and of the underlying lower grade material, is also considerable. On the other hand, it is true, as Mr. MacNeill declares, that the Nevada Consolidated has been mining its best and most cheaply available ores, and that costs must necessarily increase as the extension of the workings on Copper Flat involves the removal of a greater thickness of overburden. Mr. MacNeill, however, while calling attention to the cotton-back on the cloth admits the lustrous silken side of the Nevada velvet.

METALLURGICAL methods at Pachuca, Mexico, forms an attractive article by Mr. John M. Nicol, in the February issue of *The Mining Magazine.* The best available metallurgical talent is concentrated upon the problem of silver extraction in Mexico, and every fresh contribution to the subject is eagerly read. Other notable articles in the same number are 'Mineral Resources of Manchuria', by Mr. Thomas T. Read, 'Copper Mining in South-Western Alaska', by Mr. W. M. Brewer, and a clear and helpful word of advice from Mr. W. Truran upon 'Sketching' for the engineer. The department of discussion contains unusually valuable criticism of a technical nature touching problems in gold dredging, the Mahn dry-chlorine process, and a note by Mr. John S. MacArthur on the precipitation of gold and silver from solutions. These matters afford Mr. T. A. Rickard opportunity for some illuminating editorial comment. He also reviews in an interesting manner the career of the Guggenheim family, which is remarkable in many ways. There is a particularly well informed editorial on mining in Sonora, and a wise endorsement of the growing practice of including the consulting engineer in the directorate of mining companies. A note on the publicity required of mining companies in England, and the restrictions as well as safeguards of secrecy provided for so-called private companies, will prove suggestive of reforms needed in this country.

Snowslides in the Coeur d'Alene.

Appalling disaster from snowslides has overtaken the mining communities at the headwaters of the Coeur d'Alene river in the Bitterroot mountains of Idaho. The centre of damage was in the narrow gorge of Canyon creek, where the towns of Mace and Burke were destroyed, entailing the loss of more than thirty lives. Among those killed was Mr. R. H. Pascoe, superintendent of the Standard-Mammoth mine, one of the properties of the Federal Lead Company. The damage seems to have been confined to the dwellings of the miners. The mills of the Standard-Mammoth and Hecla mines have apparently escaped, but late dispatches report the destruction of the compressor and other buildings at the Aeolian mine. Avalanches in this precipitous region are of yearly occurrence, and nearly every winter claims its toll of death, but no catastrophe in the past has reached such proportions as that which occurred this week. The most serious accident of the kind was twenty years ago, when the camp at the Custer mine in Nine Mile canyon was swept, extinguishing the lives of seven men. Fifteen years ago a snowslide in Canyon creek, at the Black Bear mine, a few miles below Mace, also killed a number of persons.

Considering the nature of the country such disasters are not surprising. The bottom of the canyon

is so narrow as to barely afford room for the two railroads, the Northern Pacific and the Oregon Railway & Navigation, and a wagon-road. This narrow gorge is flanked by lofty hills of quartzite, which disintegrates and forms a loose soil opposing but little resistance to the sliding of accumulated snow. From Mace to Burke exists a steep unbroken face towering 2500 feet above the canyon, and it was here that the avalanche hurled destruction upon the helpless community huddled in the narrow defile below. Recklessness cannot be imputed to those living exposed to such dangers. It is part of the price men have to pay for persistence in industry under difficult conditions. It has led to a sorrowful result, to a regrettable accident in the doing of part of the world's work. Universal sympathy, and such aid as can be rendered, go out to the sufferers.

Geological Survey Methods.

Geology at Globe, Arizona, has been under discussion recently, and we have had the pleasure of presenting, first in articles by Mr. C. F. Tolman, and later in a re-statement by Mr. F. L. Ransome, the latest conclusions regarding that district. There have been slight differences of opinion, and Mr. Ransome has found occasion to correct some earlier conclusions; which as a thorough scientist he was glad to do. For our part we must regret that an error in our editing misled Mr. Ransome in discussing Mr. Tolman's conclusions. However, the point of major interest is not the age of the Schultze granite, but some questions Mr. Tolman raises as to the methods and work of the Geological Survey. Toward the latter the miners and engineers of the West have a strong feeling of loyalty. The relation of the Survey to their work is so close that they have somewhat of a feeling of proprietary interest and have never hesitated to suggest and criticise, feeling that it was 'all in the family'. This is a healthy situation, and we believe the Director and the men of the Survey would not have matters otherwise.

In the West the energies of the Survey have been directed so exclusively to the detailed study of individual districts as to have left relatively untouched many broad fields of investigation which it, alone, can occupy. A magnificent series of monographs and professional papers discussing in great detail individual mining districts has been published. These have been of the greatest service and have been fully appreciated. But where are the corresponding general studies, the accurate comparisons of district with district, the patient following of the vagaries of ore-shoots for example through numerous areas so as to permit valuable comparisons and generalizations? The men of the Survey are excellently prepared to make such studies, but the methods adopted have precluded much being accomplished. There has been an emphasis, if not overemphasis, on detail and on areal work. Even in the latter the policy of microscopic study of small areas has been pursued to such an extent that nearly thirty years after its establishment the Geological Survey still represents on its maps, great areas of the West as wholly unsurveyed. They are left as blank as central Africa before Stanley's time. It is true some general reconnoissance work has been done, such as Mr. J. E. Spurr's study of southern Nevada, followed by Mr. S. H. Ball's report on southwestern Nevada and southern California. Many white places none the less remain on the map, and there are large regions within which one has no help from the Geological Survey. When a general study of ore-shoots, vein-walls, metasomatism in veins, classification of ore deposits, or similar subject is desired, it is necessary to go to the writings of non-survey men or to the unofficial publications of members of the Survey. Subjects which we must hold are of importance at least equal to any taken up by the Survey, are neglected or treated as incidental. The bad effects of this are shown in the case of the Globe work in that reconnoissance of neighboring areas being hurried, conclusions regarding the area itself proved in need of revision. This has happened before and will happen again. It is too much to expect or to ask that Survey men should always be right, but it is fair to ask that all proper precautions be taken to avoid mistakes, and one such precaution is the placing of greater emphasis on reconnoissance and on comparisons. It is easy to criticise and hard to administer. The Survey has always been cramped for funds. Like a prosperous university the best measure of its success is that demands upon it outrun its resources. The funds, however, will only be enlarged as a result of insistent demand, and the great expansion of resources and of activities of the Survey in recent years has not carried with it the corresponding increase in work on Western metalliferous deposits that we would like to see. It should be remembered this is the particular class of ores that it was designed to study. We would not have it do less in other directions, but we do urge the need of more broad general studies of Western regions and ore deposits.

Alaska Coal Land Values.

The Alaska coal land situation continues to be thoroughly muddled. Even so well informed a paper as the *Chicago Tribune* says editorially that if the Beveridge bill be passed the Cunningham and similar claims would be extinguished. We have already pointed out that the Cunningham claimants rest on rights believed to have been acquired under existing law. If their rights prove valid they cannot be extinguished except by condemnation and purchase. It may be proper to reserve the Alaskan coal; we believe it is, but this cannot interfere with rights already acquired under the law, and as yet there has been no determination as to whether or not the Cunningham claims are valid.

Mr. J. E. Ballaine has contributed to the gaiety of nations, if not to the solution of the matters in question, by his much advertised offer of '50 cents per ton royalty'. As often happens this single phase of his proposal has caught public attention while other, and more essential elements, are neglected. We would respectfully indicate that there is a string tied to Mr. Ballaine's offer; a string so big as to constitute a veritable steel-wire cable. Among the conditions are that the Government shall guarantee in-

terest on a thousand miles of railroad. It is provided, it is true, that interest shall be paid from the proceeds of the royalties—if the latter are sufficient. If the income from this source prove too small, the general revenue of the Government would be liable. It is further provided that no leases at a less royalty shall be granted, and that the Government shall either buy half its coal from the lessee or establish mines of its own which would necessarily ship over the lessee's railway. Nothing is said as to railway rates. Under these conditions amount of royalty to be paid is of minor importance. A wise man remarked many years ago that he cared not who wrote the nation's laws if he might write its songs. An equally wise coal operator might well profess indifference as to the royalty to be paid, so long as he held the privilege of fixing railway rates. The proposal is not to be taken seriously, and we can only suspect that it was not intended to be so taken. It will be remembered that Mr. Ballaine was concerned in the promotion of the railway north from Seward, and that when only fifty miles was finished he got into difficulties and finally lost his equity in the property. With a Government guarantee of the interest on bonds he might naturally expect to be more successful in a second venture.

Another curiously exaggerated estimate of the value of the Alaskan coalfields has been given prominence of late, and this time from a source most unlikely to make such a mistake. Our Washington correspondent this week tells the story of the voluntary appearance before a Senate Committee of Mr. Stephen Birch and Mr. J. N. Steele, representing the Morgan-Guggenheim syndicate. We are glad they took this step. It was a courageous and proper means of meeting criticism. A frank avowal of their position, plans, and purposes was made. It was shown that the syndicate includes J. P. Morgan & Company, Daniel Guggenheim, Murray Guggenheim, and S. R. Guggenheim. It controls The Northwestern Commercial Company, The Alaska Steamship Company, The Northwest Fisheries, The Kennecott Mine Company, The Copper River & Northwestern railway, and the Katalla company. Interest centres mainly in the last two because of the relation of the railway and the Katalla harbor works of the Bering coalfield.

The famous contract with the Cunningham claimants was submitted, and Mr. Birch estimated the net profit in sight to be $200,000,000. This is based upon a value for the coal in the ground of $1.80 per ton and a cost of mining of $1.40. Since the contract provides for the sale of coal to the proposed railway at $1.75 per ton, we think that $1.80 is really the value in the car and not in the ground. We also doubt greatly whether coal can be mined in the Bering river field at an average price of $1.40 per ton. Certainly it costs more than that in Washington and British Columbia where conditions are more favorable. A working profit of 40 cents per ton at the mine does not seem likely, even under the most favorable conditions as to output. As a matter of fact, conditions are not now favorable for a large output of Alaskan coal. Puget Sound coals can certainly be mined and delivered to tidewater as cheaply if not cheaper than can those farther north. There is as yet no adequate evidence that these fields are incapable of supplying the market, and the companies now in the business already have what coal-trade there is on the Coast. By the time local coal is all mined the effect of competition of Eastern coal brought in through the Panama Canal will have to be taken into account. That does not now seem likely to be important, but it is one element in an uncertain situation.

For the present, fuel costs in the Pacific States are fixed by oil production and not by coal. Existing contracts call for delivery in Alaska at 85 cents per barrel; equivalent to coal at $3 per ton. Petroleum is delivered to California coast points at 70 cents per barrel, the charge being made up of 50 cents for the oil and a 20-cent pipe-line charge. From coast-delivery points it can be sent to almost any point of consumption at a further charge of 25 cents per barrel, and at these prices every one concerned is making money rapidly. While the tendency is toward higher prices, there is no question that at even lower rates the industry would be profitable. Oil now is in fact so cheap that only about half the power used around San Francisco Bay comes from the hydroelectric companies, though they sell to the distributing companies at a rate of approximately a half cent per horse-power hour. So long as oil is available in quantity, there will be no big demand on the Pacific Coast for coal.

A most important question is how long the oilfields will continue to respond to the demand. Careful estimates covering this point have been made by a number of well informed oil producers. Neglecting possible discoveries of new oil regions, concerning which many are rightly pessimistic, and taking into account only the districts now producing, with others likely to be found in the same general region, the estimates give a minimum of 30 to 50 years before serious exhaustion need be feared. At present all such estimates are necessarily uncertain, and those given are merely the best available. Remembering that money at 5% compound interest doubles in fifteen years, it will be seen that the present value of Alaskan coal which can probably only be mined and sold advantageously thirty to fifty years in the future, is not large. The conservation of the Alaskan coal itself is one of the matters which need trouble us little. It is the conservation of future public rights in the coal which is important. There is plenty of time to study the situation and reach a satisfactory conclusion. Coal to the amount needed for present development may well be leased on nominal terms, or, if need be, given away—provided the reserves for the future be left free. On the other hand, the problem of the development of Alaska is a present one. Large capital is necessary to carry through railway and other enterprises. Adequate return on this must be assured or the money will not be forthcoming. Public opinion will sanction a liberal policy designed to meet the present wants of the Territory in the line of development. The real popular objection to 'syndicate control' is not to giving adequate returns on present investments, but to mortgaging the future by heavy discounting of profits.

Rock Drill Bits.

Written for the MINING AND SCIENTIFIC PRESS
By T. H. PROSKE.

The success of almost every drilling operation depends on the selection and treatment of the bits. Too much attention cannot be given this important part of the work. If the bits have been properly formed, sharpened, and tempered for the work, and if they are changed just as soon as their edges and gauges are worn, the result will be found to be most economical. The power-drill sharpener has removed many of the shortcomings attendant upon the hand-sharpening process, with the result that where these machines are used it is possible to accomplish from 25 to 100% more drilling than under the old methods. The reasons for this are that the power sharpener turns out a much better bit. The saving in the blacksmith's wages should be a secondary consideration. The superior quality of the bits made in a machine will increase the capacity of the drilling machines sufficient to pay handsome dividends on the cost of the power sharpener.

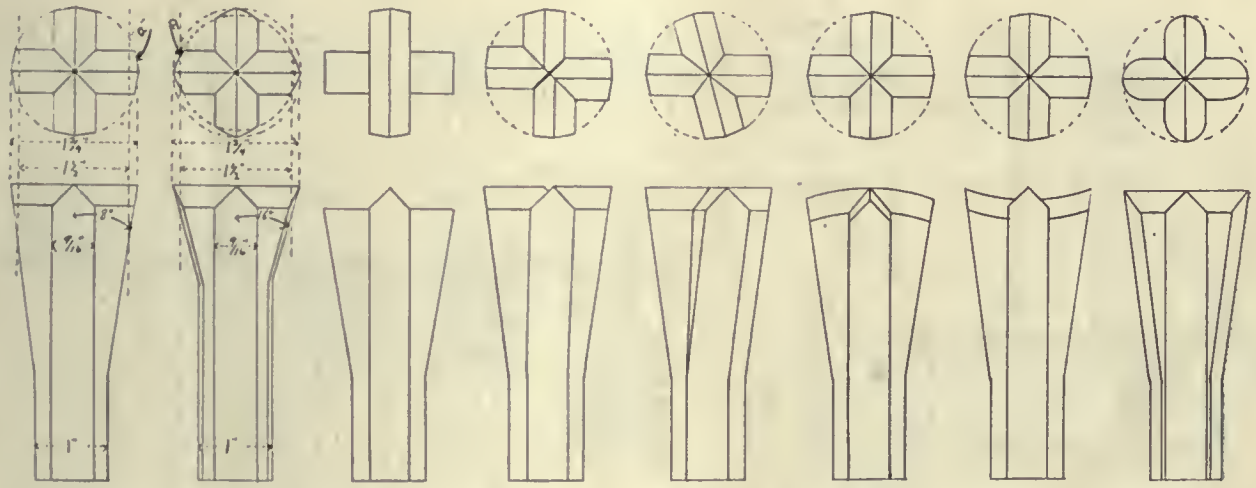

Fig. 1. Fig. 2. Fig. 3. Fig. 4. Fig. 5. Fig. 6. Fig. 7. Fig. 8.

For the guidance of those unfamiliar with the forms of drill-bits used in the different sections, I have prepared a few drawings of those in use. Fig. 1 represents the square cross-bit adopted as the standard for American mining practice. It is made from either round, octagon, or cruciform steel. In the copper mines of Michigan, it is usually made of a round steel. In the iron mines of Michigan and Minnesota and wherever this form of bit is used east of the Rocky Mountains, octagon steel is preferred, but in the Rocky Mountain and Pacific States cruciform steel is used. The reason for the adoption of this form of bit as a standard will be appreciated when the three requirements of a rock-drill bit are recalled. These are, 'to chisel out a hole in the rock', 'to keep this hole round and free from rifles', and 'to mud freely'. There is really a fourth requirement, which is 'to do as much drilling as possible before being re-sharpened'.

The different kinds of rock to be drilled affect the wear of the bit. Very hard rock will blunt the chisel and reaming edges. The softer rocks do not blunt these edges, but wear the outer sides so that it loses its gauge and size, still appearing to be quite sharp. For this reason a bit that is made with a square edge and a clearance angle of 8° will drill about four times as long in soft rock as a bit with round edges and a clearance angle of 16°, before being reduced to the size of the next bit that is to follow. Referring to Fig. 1 and Fig. 2, the latter being a round-edge bit with a clearance angle of 16°, it will be seen that in Fig. 1 the corners of the bit at the base of the bevel describe a circle that is equal to the circle that the chisel edges describe. This is as it should be, as it is impossible for the chisel edge to cut out all of the rock. The reaming edge, which is that part of the bit extending from the chisel edge to the base of the bevel, marked 'A' in both Fig. 1 and Fig. 2, must ream the outer edge of the hole and keep it round and free from rifles. In Fig. 2 it will be noted that the circle described by the corners of the bit at the base of the bevel is much smaller than the circle described by the chisel edges. This causes an excess of wear on the corners of the chisel edges, the bit rapidly loses its gauge, as well as its efficiency, and it is almost impossible to keep the hole round. Rifles form, and these cause the rotation parts of the drilling machine to break, often resulting in the loss of the hole.

The angle of the bevel of the face of the bit has to do with its life as well as with the property of 'mudding' freely. It is generally accepted that if this angle be 90° it gives strength and permits the bit to 'mud' or throw back the cuttings from the face of the bit when the drill is pointed downward. Bits made like Fig. 19 and Fig. 20 will not 'mud' freely. Another reason why bits such as is shown in Fig. 1 are preferable to those illustrated by Fig. 2, is that having a long wing they are stronger and will not break so readily as does a short bit.

The Simmons bit, used at the Champion mine at Beacon, Michigan, is shown in Fig. 3. In it two of the wings are devoted entirely to reaming and keeping the hole round and free from rifles. Some tests made several years ago in jasper, the hardest rock found in the Champion mine, using a 2¾-in. Rand drill with 60-lb. air pressure at the compressor, showed an average speed per minute of 0.28 in. for the ordinary cross-bit, and 0.659 in. for the Simmons bit. Both forms were hand-sharpened.

The Brunton bit, the invention of the well known mining engineer, D. W. Brunton, is extensively used in Idaho and Montana. It is shown in Fig. 4. The object of this bit is to obtain the advantages of the X-bit without the attendant difficulties of re-sharpening. With this bit, as in the case of the X-bit, the piston must revolve a half turn before the cutting edges will strike in the same place a second time. It is as easily re-sharpened as the regular square cross-bit. The X-bit itself is shown in Fig. 5. Since the invention of power-drill sharpening machines, this bit is fast disappearing. The reason will be understood when a comparison is made with the regular square cross-bit, as made with the power-sharpener, and the cross-bits as they are re-sharpened by hand, shown in Fig. 18, Fig. 19, and Fig. 20. The X-bit is designed to prevent rifles. This the hand-sharpened cross-bit would not do, but the machine-sharpened cross-bit effectually accomplishes. Fig. 6 shows what is commonly termed the high-centre bit. This was for many years accepted as the proper form. It is still used in the mines of Cornwall and where Cornish customs prevail. Since the introduction of hammer-drills this bit is again finding favor. It is of especial advantage in starting a hole, the high centre immediately making an impression on the rock, whereas the square-faced bit requires a flat face for ready starting. For a starting bit in hammer machines it has no equal. Here, however, its advantages over the square bit end. Used as a bit to follow the starter, it is liable to follow slips and seams in the rock, causing crooked holes, which are sometimes lost before being finished. This the square bit will not do. Fig. 7 shows a bit where the corners are in advance of the centre. This is a fast cutting bit. The corners break up the rock in advance of the centre and leave little for the centre to do; this causes the corners to wear fast, but still not to excess when it is considered that they do most of the work. This drill will not follow slips and seams, will drill a round hole, and is easy on the drilling machine. The weak point of this form is that the leverage is so great on the corners that they are liable to break off if tempered too hard. Fig. 8 shows the round-edge bit, which is a favorite with some. In soft rock this is good, but in hard rock it permits rifles to form in the hole because there are no reaming edges.

The Y-bit, shown in Fig. 9 gives the advantage of plenty of room for the cuttings to escape. It is, however, quite difficult to make and re-sharpen by hand. With the power-sharpener it can be made as easily as any other form. Fig. 10 shows the 'bull' bit in use in the lead and zinc mines of the Joplin, Missouri, district, before the introduction of the power-sharpener. The extreme hardness of the limestone and flint in the sheet-ground of that district, caused the ordinary cross-bit as made by hand to wear too fast. This dull bull-bit therefore had to be adopted. Drilling here was not a matter of cutting the rock, but of shattering it by impact. The power-sharpener has changed all this, and the American standard cross-bit as made in these machines is now used. As a result the capacity of the drills has been materially increased. In mines where hand-sharpening is still done the bull-bit is yet in use. Fig. 11 shows the Z-bit used in hand-sharpening in the southeast Missouri lead district. This bit is also used quite extensively in Germany. In both places, however, the advantage of the standard square cross-bit as made with the power-sharpener is fast causing it to be displaced. Fig. 12 shows the 'six-wing rosette' bit as made in the power-sharpener in use at the Penarroya mines of Spain. It is used in hammer drills only. Of all the rosette forms of bit this has been found to be the most satisfactory. Fig. 13 shows the square cross-bits when made up for hammer drills where a hole for the introduction of air or water to remove the cuttings apexes at a point back from the bevel of the bit in one of the recesses between the wings. Fig. 14 shows the same form where the hole ends in the centre of the cross of the cutting edges. This form of bit is extensively used. Its faults are that a core is formed by this hole; this core fills the hole, and causes a stoppage of air or water. These cores have been known to become as much as 8 in. long, and are quite difficult to remove. To clear them away the core must be burned out by heating the steel the full length of the core in a slow fire: a sometimes slow and tedious process. This difficulty is entirely overcome by the use of the bit shown in Fig. 13. The Z-bit, Fig. 15, is extensively used in Germany. In hammer drilling machines, the steel is formed in bars having a Z shape. While I show this bar straight, it is usually twisted to form a spiral.

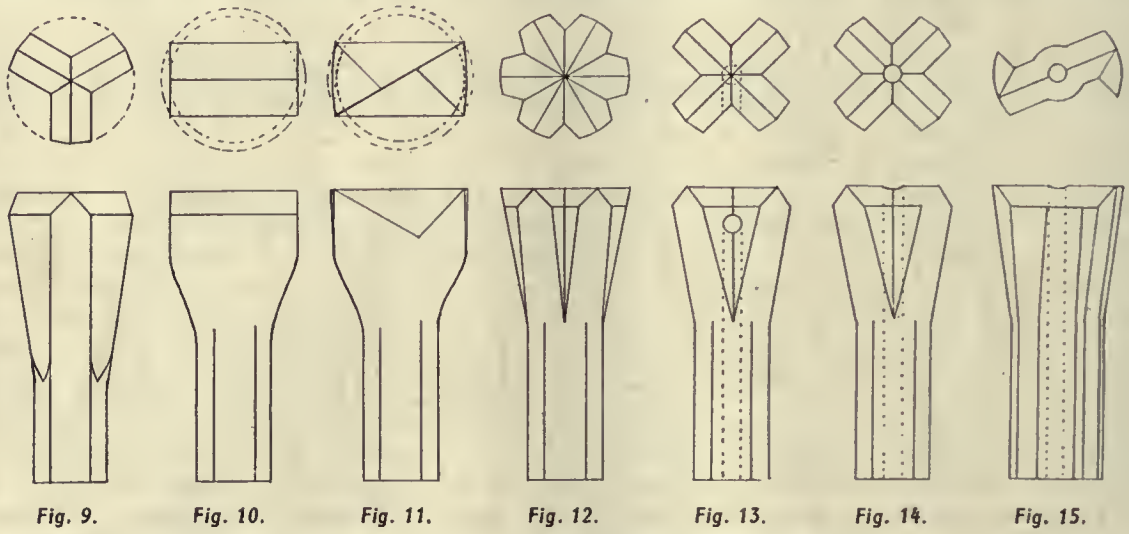

Fig. 9. Fig. 10. Fig. 11. Fig. 12. Fig. 13. Fig. 14. Fig. 15.

It is an easy matter to form a Z-bit on the end of such a bar. The results obtained are excellent. Holes to a depth of 16 ft. horizontal have been drilled with this form of steel. The spiral draws out the cuttings much the same as an auger. Fig. 16 to Fig. 20 are given to show the evolution of the cross-bit where hand-sharpening is employed. There are two systems of hand-sharpening. One is known as the set-hammer system. In it the steel is hammered by placing a set-hammer on the bevels and driving the steel back. The results of this method are illustrated in Fig. 16 to Fig. 19. Fig. 16 shows a bit made by cutting the bevels with a chisel and is as it should be in form. Fig. 17 shows this bit after about the third sharpening. Fig. 18 is the same bit after about the sixth sharpening, and Fig. 19 is the same bit at about the time that the original cross that was formed on the bar of octagon steel has become exhausted. The other system of hand-sharpening is known as the fuller and dollie system. By this system the stock is first drawn sharp at the corners as shown in Fig. 20 with the fuller, after which it should be set back in the centre with the dollie. Unfortunately the man swinging the sledge hammer gets tired before the bit is set back enough, the result is that the bit, partly finished, is left as shown in Fig. 20. It is because the power-sharpener has the staying power, and because it readily finishes a bit perfectly, that inferior bits like these are not to be found where machine sharpening is employed.

Fig. 16. Fig. 17. Fig. 18. Fig. 19. Fig. 20.

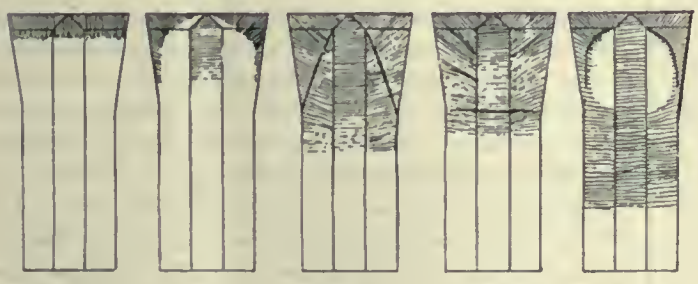

Fig. 21. Fig. 22. Fig. 23. Fig. 24. Fig. 25.

After a bit has been forged, it should be properly tempered as in Fig. 21. Fig. 22 shows the result of the common method of tempering. The centre of the bit is soft, while the corners are hard. When the bit is immersed in the water about an inch the large mass of metal in the centre cools more slowly than the corners since the corners have three sides exposed to the water. Perhaps the centre had not chilled at all when the bit is withdrawn for annealing, and the final result is a soft-centre bit, which will flatten and retard the work of drilling. Fig. 23 and Fig. 24 show the result of trying to temper the bit with the forging heat, by plunging the whole bit into the water as soon as it is sharpened. The line of tension induced by cooling is indicated. At this place the drill will break. Fig. 25 shows the checking caused by first chilling the steel back of the bit and then plunging with the forging heat.

For the purpose of tempering a bit as shown in Fig. 21 a tank should be provided, such as shown in section in Fig. 26. This should be about 12 in. deep by 12 wide, and of sufficient length to accommodate whatever number of drills are to be sharpened in a day with the machine. The water inlet should be at the bottom, and the outlet should be placed about ¾ in. above a grate which itself should be about 8 in. above the bottom. This permits the bit to be immersed to a depth of about ¾ in. With a temperating tank of this construction the bit can be hardened to any desired degree. This depends on the temperature of the bit when placed on the grate. It is essential that the drill stand in a vertical position. To lean either way would cause it to harden to a greater depth on one side than on the other, causing a tension that might lead to breaking of the wings. It is best to provide a rail around the tank about the distance above required to hold the shortest drill, and to drive pins about 3 in. apart in this rail. By placing the drills between these pegs they can be kept in a vertical position. When using this tank a small flow sufficient to displace the water heated by the cooling of the bits should be turned on to keep the supply always cool.

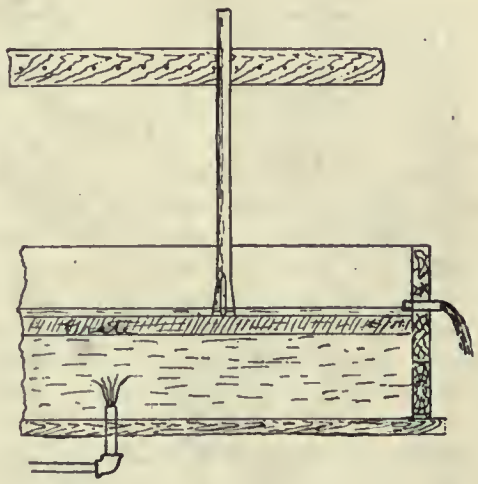

Fig. 26.

Tests are being made at the Pittsburg station of the U. S. Geological Survey of all types of lamps used for lighting purposes within mines with respect to their safety in the presence of explosive mixtures of coal gas and air. The candle-power of all safety lamps is determined for different kinds of oil used in mines, and electric portable lamps are also being tested in like manner as to their candle-power and their safety in explosive mixtures of gar and air. The tests are made in currents of air running at different velocities and charged with explosive gas.

The Cebu coalfields have been known for some time, but have remained undeveloped. The prospect for development of the deposits of Danao are brighter now than at any previous time. The necessary capital has been pledged to make the enterprise a success. The coal is of good quality and has been used successfully by inter-island steamers.

Piz-Piz District, Nicaragua.

Written for the MINING AND SCIENTIFIC PRESS
By W. A. CONNELLY.

The Piz-Piz gold mining district is in northern Nicaragua, about seventy-five miles in a direct line from the Atlantic coast, lat. 14°N., long. 84°30′W. The district is reached from the United States by steamers of the Bluefields S. S. Co., which runs a boat twice each month to Cape Gracias á Dios, a port at the mouth of the Coco or Wanks river, and four or more boats to Bluefields, a port farther south. From Bluefields it is necessary to take a coasting schooner to Principulca at the mouth of a river of the same name, thence by batteau up the Principulca and Banbana rivers to Tunkey, a small town near the head of navigation on the Banbana. This town is 20 miles distant from the mines, and the trip must be made on mule-back.

The Cape Gracias route is the one most generally used, as there is a commodious river steamer

Map of Nicaragua.

plying weekly from the port to the mouth of the Waspue river, a distance by windings of the river of about 200 miles. From the mouth of the Waspue to the mines, by the Waspue and Piz-Piz rivers, freight is carried in batteaux, poled or paddled by Mosquito or Sumu Indians. These boats carry from 5000 to 8000 lb. of freight and the crew. Power-boats are not feasible above Ya-hook falls, in the Waspue river, as there are numerous rapids and three or four portages.

The trip from New Orleans to the mines usually requires from 12 to 15 days, divided as follows: New Orleans to Cape Gracias five days; at the Cape one day; two days on river steamer to Waspue; and four to five days from Waspue to the mines. The expense of the trip is about $100, and to one fond of water travel it is extremely pleasant. This section of the country needs a railroad badly. There are two possible short routes, both in conjunction with river transportation. From the Waspue, the head of steam navigation on the Wanks, about 60 miles of road would suffice to reach the mines. The country through which this road would pass is fertile and could be made to produce great quantities of bananas and tropical fruits, besides being a fine natural grazing country. The road would enter the gold belt within 15 miles above the mouth of the Waspue.

The other route from Walpatara rapids on the Banbana river would have a length of about 30 miles, would enter the gold belt at once, and would serve the mines below Tunkey, as well as the Piz-Piz district. A narrow-gauge road could be built and equipped, in a modest way, for about $5000 per mile. A future for a road could be had by extending it through Jinotega and Matagalpa to Corinto on the Pacific coast. The climate of this part of Nicaragua is tropical, the temperature in the daytime being about 80°F. and at night about 75. There are two seasons, wet and dry. The wet season begins usually about June 15, with heavy rains till about September 15, lighter rains till December, then continuing heavy again till January or February. There is never a shortage of water for milling. The whole country is densely covered with tropical vegetation, including a good supply of hard-wood for mining and building purposes. Tropical fruits and vegetables grow in great abundance the year round, some of the most useful being banana, plantain, casava or yuca, sweet potatoes, yams, limes, citronella, oranges, papaya, and pineapples. Mexican beans and corn are raised by native farmers; many of the common northern vegetables are being successfully cultivated at the mines.

The mines are situated on the southeasterly slope of a prominent range of hills which forms one of the main water-sheds of the Republic. This range of hills, beginning not far from Cape Gracias, extends in a general southwesterly direction several hundred miles into the interior of the Republic, traversing its widest part, then westward to the Pacific coast. The water of the northeastern slope flows to the Wanks, and thence to the Carribean sea; the opposite slope is drained by a number of large short rivers to the Lake of Nicaragua and the Carribean sea. The general elevation of the district is about 1000 ft., with hills as high as 1800 to 2000 ft. above sea-level.

No work has been done by the Government in geological investigation, and little is actually known of the geology. Vegetation covers the whole country, and the excessive rainfall has caused great weathering and erosion, so the hills are invariably rounded, and the surface is a red clay. The country rock of the Piz-Piz district is a flow or succession of flows of andesite, much fractured and highly altered near the surface. The alteration, as shown at the mines, extends to a depth of 150 to 200 ft., making early development easy.

The vein systems have a strike about N.52°E., and a dip of about 70°N.W. Most of the smaller veins follow closely the strike and dip of the so-called 'mother lode'. This mother lode has been traced, and considerably developed, along a distance of 20 miles, and is thought to extend much farther. It is a true fissured zone, 25 to 75 ft. thick, having a quartz-iron filling, much weathered to a depth of 100 ft. or so. The surface has been eroded, and the finer particles washed away, leaving a *manta* of concentrated ore wider than the vein and somewhat richer.

The gangue has weathered more slowly than the enclosing country rock, thus leaving the vein exposed in a plainly visible outcrop along its length. This vein has large bodies of ore with an average assay value above $6 per ton, which are being quarried or worked by 'glory holes'. Near by, on either side of the great vein, are smaller ones, from 3 to 20 ft. thick, being either branched or parallel veins, with the same filling, but with more iron. The ore in these smaller veins is much higher in grade and the gold is of greater fineness. There are many large well defined veins in the surrounding country of which little more than their existence is known.

Gold was discovered about 20 years ago in the creeks of this district, and soon after the veins furnishing the gold were discovered and denounced. The working mines today, with their equipment, are as follows: Bonanza, Joe Lapierre owner, eight 3½-ft. Huntington mills, sand leaching plant, and decantation slime-plant, hydro-electric power plant; Lone Star, Norman McInness and William Bluett, owners, thirty 750-lb. stamps, sand leaching plant, water-power; Mars, S. B. Sherrick and Charles Lobner, owners, two 3½-ft. Huntington mills, hydro-electric power plant; Siempre Viva, Bluefields and New Orleans company, owners, twenty 650-lb. stamps, sand leaching plant, hydro-electric power plant, generating 300 kw.; Constancia, New York company, owners, ten 850-lb. stamps, water and electric power, buying power from Siempre Viva; Concordia, Paul Rener, owner, ten 750-lb. stamps and log-washer, electric power from Siempre Viva; Trinidad, Richard Lehmann, owner, five 750-lb. stamps working the extension of the Siempre Viva vein east, using electric power from the Siempre Viva.

The Bonanza is working a deposit or *manta* averaging about $6.40 per ton, and owing to the ease with which it can be mined, the working cost is low. The Lone Star and Mars are milling ore from the 'mother lode', mining it by open pit or mill-hole. Concordia and Siempre Viva are using ore from a large vein paralleling the main lode, and mining through adits, no pumping nor hoisting being done. Constancia is taking ore from two smaller side veins and from the main lode, the latter by open pit and the former through a shaft by a small electric hoist.

Besides the above named mines several new properties are doing well, with only 3 stamps and other prospecting mills. The output of the district is about $550,000 per year.

Up to the present time only ore from a comparatively shallow depth has been used, and with the existing milling plants there is enough ore of the same character to last for many years. Just what the ore will be like in depth is not known, but in the deepest levels run on some of the mines, sulphides in small quantities have been found. These sulphides are iron pyrite, chalcopyrite, zinc blende, and galena with some pyromorphite and anglesite. When the completely oxidized ores have been exhausted it will likely require a different treatment than is now applied.

This district is supposed to be inside the boundaries of the mining concession, held by a few Pittsburg men, under the name of the U. S. & Nicaragua Co. This company has played the dog-in-manger for eight years. Their boundary lines have never been drawn, nor have they done any exploration worth mentioning, nor built one milling plant. This means that a magnificent mining territory 25 miles wide, reaching nearly across the Republic, has been withdrawn from entry, and that there is absolutely no use being made of it. It is hoped that this concession will be cancelled and that the Piz-Piz district will be allowed to resume the rapid growth checked so suddenly eight years ago by this useless monopoly.

The power possibilities are splendid. The upper Piz-Piz falls, owned by the Siempre Viva mine, are thought to be able to generate 2500 hp. The lower falls, owned jointly by the Mars mine and the Concession, will generate twice that amount. The Bonanza mine has a 100-kw. plant now, with a possibility of increasing it greatly. The Lone Star has water-power sufficient for 500 hp., provided a hydro-electric plant were installed at its falls. The United States & Nicaragua Co. hold all the lower falls on the Piz-Piz except 200 hp. owned by the Mars mine, and it lays claim to all others not now in use.

Labor, consisting of Spanish, Mosquito and Sumu Indians, and Grand Cayman Creoles, is plentiful and cheap. Miners receive 2.5 *soles*, muckers 1.5, car-men 2, timber-men 3 to 4. Creole amalgamators get 4 to 5 *soles* and mine foremen the same. The shift in the mine and all other work except in the mill is 9 hr., and the men are paid in silver, the *sol* being the unit. The value of the *sol* fluctuates with the price of silver. It has been worth 40c. gold for almost a year past. All men are fed by the mine owners. The rations are about as follows: wheat-flour bread once or twice per day; plantain, boiled, when bread is not given; beef is bought twice each week; beans, rice, and coffee with sugar.

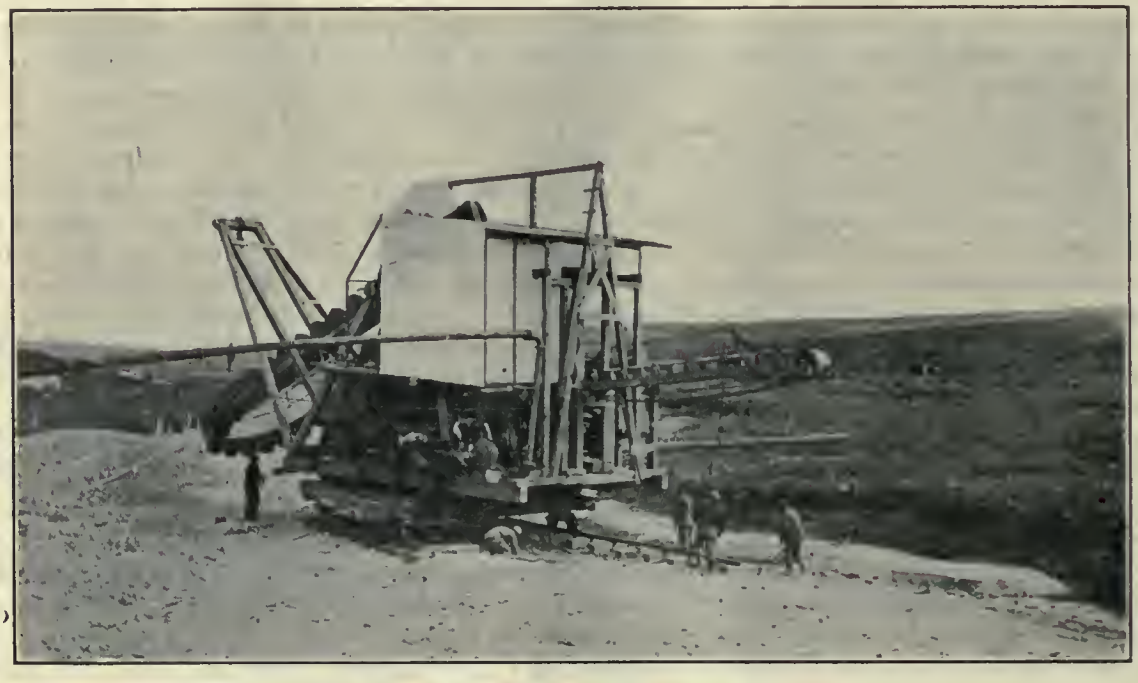
Owing to a high tariff all foreign foodstuff is expensive. Beef is killed under a concession; sugar is made by a monopoly; salt pays tribute to a concession; also dynamite, caps, and fuse. The mines now drag or carry their freight from a landing on the Piz-Piz river, a solid mortar weighing 5000 lb. being the limit of weight, which can be handled by this method. Mining machinery is admitted free of duty. There is an export duty on gold of 50c. per fine ounce, with a penalty of 50% if said duty be not paid in certain bonds issued by the Government. As these bonds were promptly subscribed for by parties in Managua, tipped off by the Government, the mines pay the penalty. The total expense per ounce is about $1, in fact one large business company charges $1.08 per bar-ounce, all charges included except those made by the Mint in New Orleans. The gold as shipped from the mines is worth from $12.50 to $16 per ounce, the higher value being for gold from the smaller veins. The pertenencia is the unit for denouncement, and is 5 hectares or 12.36 acres, and the locator has the right to the minerals within the vertical side-lines. *Planteles* or wood and water-right are granted owners of mineral rights. Taxes are 5 *soles* per hectare on mining claims and 2.5 *soles* per hectare on *planteles*, payable between January 1 and 31 of each year, and if not paid within such time, double the amount will be collected.

Pony Dredges in Alaska.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM H. WASHBURN.

Although the field of profitable placer mining has been much enlarged by the modern dredge and the hydraulic elevator, there is still a large area of placer ground not adapted to their use, or to the primitive method of shoveling into sluice-boxes. The bedrock may be too hard, the boulders too large, or the ground too shallow, to warrant the construction of a dredge, of standard size at least. A lack of cheap water with sufficient head, or the difficulty of ground so shallow as to cause a too frequent moving of the plant, limits the field of the hydraulic elevator. The mechanical elevator obviates the first difficulty, although not the last. In Nome and Council districts, Alaska, this is the case as to much of the placer ground there yet unworked, outside of that adapted to dredging. The high cost of labor in that region seems to make it a promising field for the introduction of labor-saving machinery to work ground such as that above mentioned. Much of it contains enough gold to barely pay expenses when worked by shoveling into sluice-boxes. The small floating dredge, of the ladder type, with a capacity of 500 to 1000 cu. yd. per 24 hr., generally called a pony-dredge, is probably best adapted to this class of work, where the conditions will permit of its use; and it is indeed coming into favor in that country in ground adapted to its successful operation. Several pony-dredges, originally built on wheels, have been there changed to the floating type with improved results. Still much of this ground is not suitable for even the floating pony-dredge on account of the hard bedrock, large boulders, and shallow ground. Sometimes the bedrock is blocky and full of crevices, into which the gold finds its way, and from which it can only be removed by much work.

This calls for an exposed bedrock, so that it can be cleaned up. Sometimes the gravel contains boulders so large as to seriously interfere with the work of a pony-dredge, and to cause danger of breakage. If the operator can see these boulders he can dig around them until they can be moved out of the way of the buckets. When driven to work with a so-called 'dry bedrock' (though it is never really dry, unless perhaps on a bench), the problem becomes much more complicated, and necessarily more expensive than when a floating dredge can be used. The pit is usually unwatered by a drain ditch, or pump. The first may have to be 1000 or 1500 ft. long, in order to gain the creek-level, which makes it expensive, and besides there is always danger of floods choking, or perhaps totally destroying it. The pump may have the advantage of lower first cost, but the expense of power and attendance is generally a large item.



Pony Dredge on Wheels, Ophir Creek.

Even then it becomes troublesome to keep the tailing water out of the pit as the work advances. This is really one of the greatest obstacles to the use of mechanical excavation for this class of work.

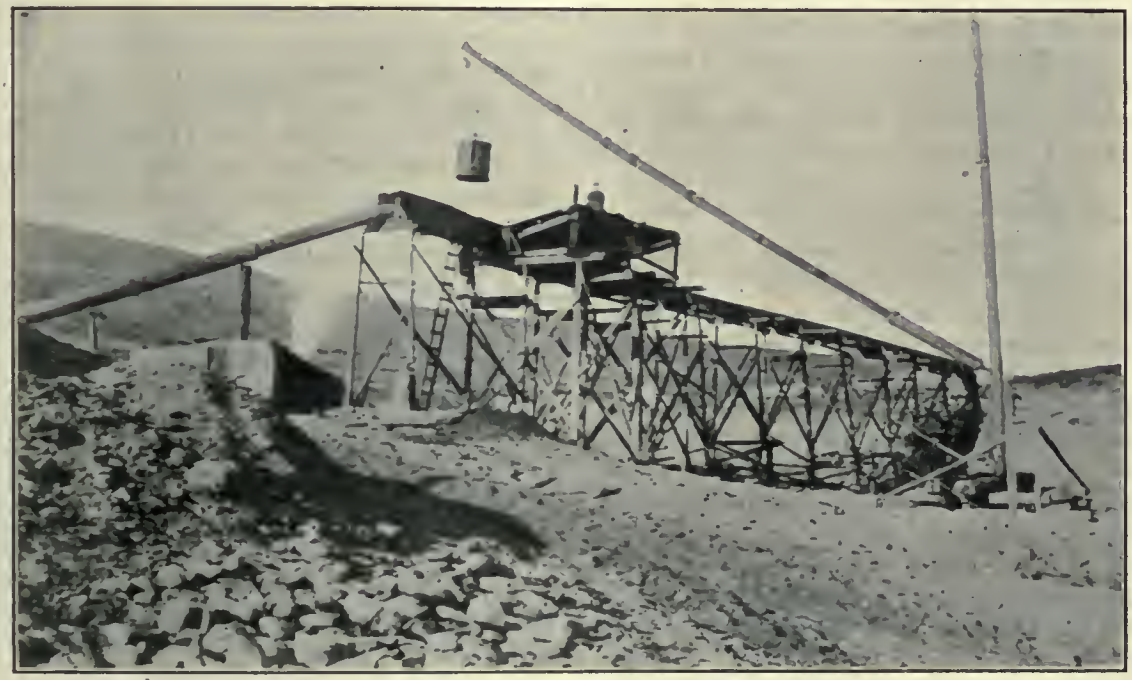
Another troublesome problem is to arrange a washing plant, having the capacity, and at the same time adaptability, for washing the gravel, and for keeping within reach of the excavator as it advances with the work. If the sluice-boxes are set up permanently, they are soon too far from the fall of the cut, and the tailing piles up at the tailing sluice, compelling their removal.

A brief review of the different plans tried for adapting machinery to this work will here be attempted. The steam-shovel has been tried from one end of Alaska to the other, and yet it has generally not run over two seasons in any one place. Its efficiency as an excavator is well known and acknowledged. The difficulty seems to be that in some cases it will not elevate the gravel high enough to allow sufficient dump for the tailing, and in nearly every case it will dig more gravel than the washing

plant can take care of, and keep within reach of it without frequent stops. If some genius can devise a way to wash the gravel as fast as the steam-shovel can dig it, and do it cheap enough, and keep the pit dry at the same time, the problem would evidently be solved.

The nearest approach to this that I know of is on Shovel creek in the Solomon River district. This steam-shovel is of the new turn-table type, mounted on wheels, on a track of heavy rails, the washing plant following behind it on the same track. This plant consists of a shaking screen over the head-box of a string of ordinary sluice-boxes, on trestles, mounted on trucks, on the steam-shovel track. The oversize from the screen is carried out at right angles to the sluice by a short elevator, and dumped into the pit, which is kept free from water by a drain-ditch. The tailing is kept out of it by a retaining wall of boulders, which is advanced from time to time as the work progresses. The bedrock is generally a hard blocky limestone, full of crevices, and yet I am informed that by careful manipulation the shovel will dig it up enough so that it does not pay to clean the bedrock by hand. It has been operating during the past two seasons with profit. Steam-scrapers have been tried, and found wanting. The power consumed, the wear and tear of plant, and the limitations of height to which it will deliver the gravel, seem to be the principal objections to its use. Some small plants are still in use in placer-work, but they do not seem completely to meet the conditions as to cost of operating and capacity required. In neither of these lines do they equal the steam-shovel. A derrick-hoist on Ophir creek has handled a large amount of gravel during the past two seasons, and seems to have a place in the field where the gravel must be lifted high, and a more expensive plant is not warranted by the gravel in sight.

The derrick mast is slightly inclined toward the sluice-box, so that, as the loaded bucket is hoisted, it and the boom swing toward the sluice, where it is dumped into the head-box by a man stationed there for that purpose. The boom is then pulled back by another man, stationed on the bank of the pit, with a pull-rope, and the bucket lowered upon one of a number of small trucks running on tracks radiating toward the face of the pit, where the buckets are filled by hand. When a new pit is to be started a duplicate line of sluice-boxes is set up, before finishing the work in the pit, leaving only the derrick and hoisting engine, cars, buckets, and tracks to be moved to begin the new pit. The cars are not, however, necessary at the start. The tailing from this pit is dumped into the one just finished, and a wall of gravel left in place between them to keep the tailing-water out. When the pit is nearly done, this wall is removed; the tailing-pile which has in the meantime accumulated, answering for a dam in its place. This device allows the ground to be worked neatly, and hoists the gravel to almost any height desired, with economy and despatch; but the buckets being filled by hand-work makes that part of the system expensive, and is only to be recommended where the special conditions seem adapted to it, such as a limited amount of gravel, and where the sluices must be at a considerable height above the bedrock. It really does not cheapen the work much, as regards the digging, which is the part which most of all requires to be lessened in cost.



Derrick and Sluices on Ophir Creek.

On the same creek, a pony-dredge of the turn-table type, on wheels on a track has been operated with apparent success during the past season. This machine is a ladder-dredge, having buckets of 2 cu. ft. capacity, which drop 24 times per minute; which, by the way, is faster than would be practical under the same conditions if it were afloat. The face of the cut being in sight, the boulders are avoided. This permits a faster speed for the buckets. The dredge is driven by a 35-hp. Western gasoline engine. The gravel is dropped on a screen, from which the over-

size is carried by a belt-stacker, extending behind the dredge, and from it is dropped into the pit. The undersize is passed through four lines of sluice-boxes, each 18 in. wide by 24 ft. long, lined with angle-iron riffles, and set on a grade of 1¼ in. to the foot. This is equivalent to one sluice 72 in. wide by 24 ft. long. These sluices are on the dredge, the plant being self contained. The tailing and water from the sluices are taken up by a 5-in. centrifugal pump, and forced through a 6-in. pipe, 60 ft. long at right angles to the dredge, where it is dropped outside the pit, and about 15 ft. above the pump, the tailing water being conducted away from the pit to the creek bottom.

The pit is drained of seepage water by a ditch extending along one side, the ditch having been excavated by the dredge. The bucket-ladder has a swing of 48 ft., and the dredge is advanced about 4½ ft. at a time. The track is laid with 60-lb. rails. Water is supplied from a ditch through a pipe-line ending in a flexible hose to allow for the swing of the dredge. The average depth of the ground is about 12 ft. There are a few boulders in it, too large for the buckets to handle, but these being visible, the gravel is dug from around them, and they are then moved out of the way of the buckets. This allows a faster bucket-speed without increasing the danger of breakage, and there is also a saving of power in avoiding useless bucking up against the boulders, as would be sometimes unavoidable if under water. The bedrock is taken up by the dredge deep enough to make cleaning by hand unnecessary. The capacity of the dredge is about 500 cu. yd. per 24 hr. It is run by two men on the dredge (one of whom is a capable machinist), and two men in the pit attending to track and other details. The machinist is the only skilled man required in the crew.

This machine being self contained, and delivering the tailing outside the pit, seems to have considerable merit. In this case, however, the bedrock being soft enough to be taken up by the dredge, the only reason for mounting it on wheels appears to be the few boulders in the gravel that are too large for the buckets to handle. I venture the opinion, however, that the advantages of the floating type of dredge would, in this particular case, more than make up for the drawbacks which the boulders entail. If the bedrock had to be cleaned by hand the case would be different, and the dredge on wheels would be more suitable for the work.

In conclusion, taking into account the concensus of opinion of those who have used the different types of machines above described, I believe that while the steam-shovel is a good digger, the separate washing plant it requires, causing additional expense and delays in moving it, makes it difficult to adapt it to this class of work. The steam-scraper consumes too much power per cubic yard, and unless the ground is shallow it does not allow sufficient head to take care of the tailing.

The floating dredge, of a capacity governed by the amount of ground available, seems to be the machine which will excavate and wash the gravel cheaper than any of the other appliances described, but the bedrock and boulders must be taken into account before its installation.

Yerington Copper District.

By F. L. Ransome.

*The town of Yerington is in Lyon county, in that part of western Nevada which lies between Tahoe and Walker lakes. (See Fig. 1.) The nearest railway station is Wabuska, 12 miles to the north, on the Hazen-Mina branch of the Southern Pacific. The town lies in the middle of Mason valley, through which Walker river flows. The principal mines are in the mountain ridge west of town, of which the Indian name is said to be Singatse,[1] but which J. E. Spurr[2] has called the Smith Valley range.

The geology of the region adjacent to Yerington received little attention from the earlier explorers. The only publication according it more than incidental reference is the paper by D. T. Smith, already mentioned, which is accompanied by a geologic map based on the topography of parts of the Wabuska and Wellington atlas sheets of the United States Geological Survey. The rocks in the Yerington district are readily divisible into two groups markedly different in age and structure. The older group consists of schist and limestone with intrusive masses of granodiorite, or quartz monzonite, and related porphyries. This assemblage of rocks was called by Smith the 'bedrock complex', a name which it is not desirable to perpetuate, and which will doubtless be replaced when detailed geologic work is undertaken. The granodioritic or monzonitic rocks were by him designated 'granite', 'granite porphyry', and 'porphyrite', although his own petrographic descriptions appear hardly to suggest these names. The younger group, called by Smith the 'superjacent series', is of volcanic origin and rests with obvious unconformity upon the older complex. It may in turn be divided into two parts, namely, (1) a series of rhyolitic flows and tuffs, bedded volcanic grits, andesitic tuff, and andesitic breccia, and (2) an unconformably overlying flow of basalt.

The schist, which is the prevailing rock in the canyon heading near the McConnell mine, is cut by many irregular dikes of granodiorite or granodiorite porphyry and is in places stained by salts of copper. On both slopes of Singatse ridge masses of limestone are intricately enfolded with the schist. Some of the limestone is a pure gray crystalline variety which is not noticeably metamorphosed and in which the bedding is distinct. Other parts of the formation, however, are intensely metamorphosed. The relation between the limestone and the andesitic schist is so intimate as to leave little doubt that a series consisting originally of andesitic rocks, limestones, and perhaps some tuffs and shaly sediments has been folded, squeezed, and mineralogically changed at the same period and by the same set of metamorphic processes. The cause of the metamorphism was the

*Abstract from 'Contributions to Economic Geology, 1908'. U. S. Geol. Surv., Bull. 380.

[1]Smith, D. T. 'Geology of the Upper Region of the Main Walker River, Nevada'. Bull. Dept. Geol. Univ. Cal., 4, 1904, pp. 1-32. The name is printed Sing-ats-e in this paper.

[2]'Geology of Nevada South of the Fortieth Parallel'. Bull. U. S. Geol. Surv. 208, 1903, p. 117.

intrusion of the granodiorite and closely related porphyries.

From Mickey Pass (see Fig. 1) southward to the latitude of the Western Nevada mine the granodiorite occupies in general that part of the ridge which lies between the summit and the eastern belt of limestone. South of the Western Nevada mine the granodiorite appears to make up a larger part of the ridge, and at the south edge of the area included on the map this rock extends practically to the river. The granodiorite of Singatse ridge is a rock of general granitic appearance and for the most part of evenly granular texture. The low hills north of Mason Pass and along the road from the pass to Yerington are composed mainly of granodiorite porphyry, which is generally more or less altered. This rock is stained with copper salts in many places, particularly about capped by olivine basalt. These remnants occur at various elevations, ranging from 4500 to 6500 ft. They rest generally on the granodiorite, schist, or limestone, and this fact suggests that the older Tertiary rocks were deformed and much eroded before the basaltic eruptions began. Although the basalt has probably been faulted, and in places may have been gently tilted, it nowhere shows dips as high as those of the rhyolitic and andesitic rocks.

The general distribution of the important mines and prospects near Yerington may be seen from Fig. 1. One group, the members of which are similiar in the character and geologic relations of their orebodies, lies on the east slope of Singatse ridge southwest of Yerington, about halfway from valley to crest. Together they constitute a chain two miles in length, the mines from north to south being the Blue-

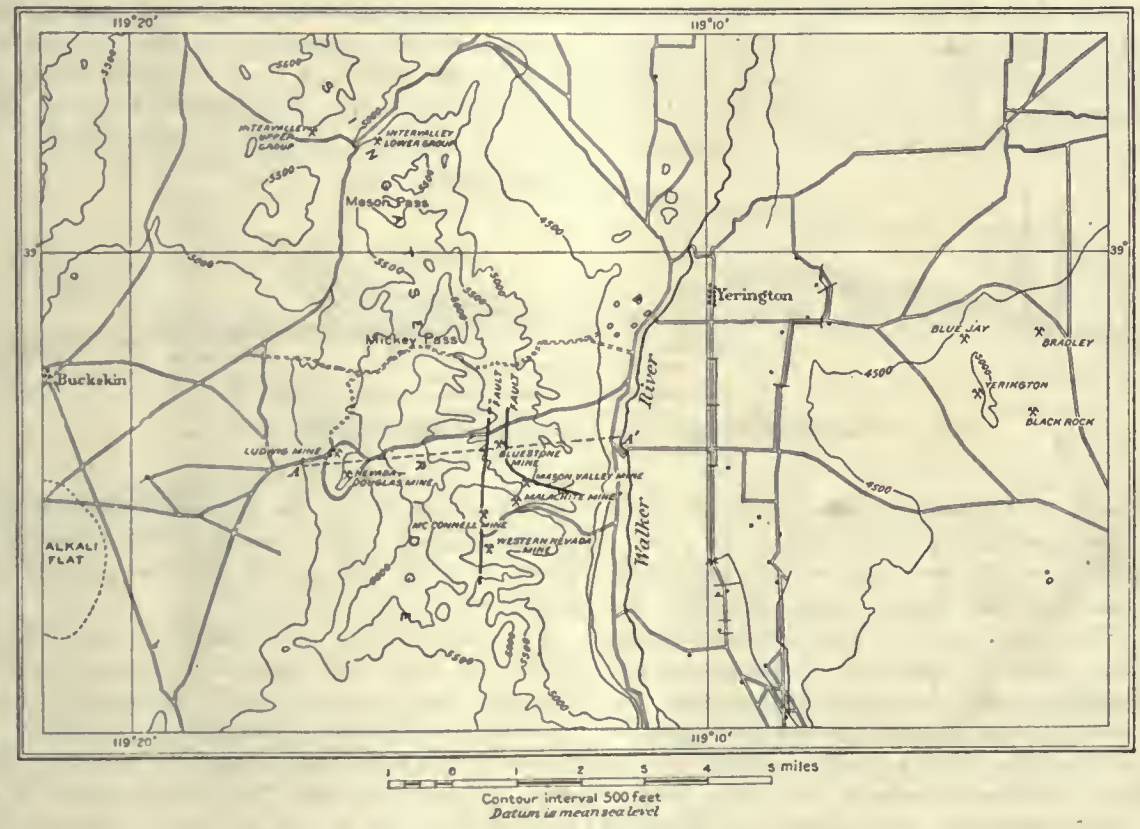


Fig. 1. Map of Yerington District. A-A′ Line of Cross-Section.

1½ miles west of the town, where an attempt was made some years ago to mine and smelt the copper-stained porphyry. The prevailing rock of the hills which contain the Blue Jay, Yerington, and other mines southeast of Yerington, is granodiorite, or quartz monzonite, similar in texture to that of Singatse ridge, but generally fresher and darker. That not all of the granodiorite and granodiorite porphyry was intruded simultaneously is clearly shown in the hills southeast of Yerington, where the main mass of granodiorite is cut by porphyry dikes of similar chemical and mineralogical character.

The Tertiary lavas and associated sediments are younger than the ores. Their general relations to the older rocks and to the structure of the ridge is illustrated in Fig. 2, which is partly diagrammatic and makes no pretense to refined accuracy. Rhyolite makes up a large part of Singatse ridge north of Mickey Pass. South of the McConnell mine several of the spurs and summits of Singatse ridge are stone, Mason Valley, Malachite, McConnell, and Western Nevada. Most of these mines have shipped some oxidized copper ore, but operations at present are confined to development in the sulphide zone or, at the Mason Valley mine, in a zone of mixed oxidized and sulphide ore. These mines are from four to eight miles from Yerington by wagon-road. The history of all goes back thirty years or more, but none has produced abundantly or continuously. At the western foot of Singatse ridge are the Nevada-Douglas and Ludwig mines, now under one ownership, the Nevada-Douglas Co. having bought the Ludwig in 1907 for about $500,000. By the direct but steep road over the ridge past the Bluestone mine the distance from Yerington to these mines is about seven miles. The Mason Pass road from town to the Ludwig mine is about twice as long, but is much used because of its better gradient. Both the Nevada-Douglas and Ludwig are old mines and have intermittently produced considerable ore; how much is

not known. The Ludwig ore has of late been hauled by a traction engine to Wabuska. About a mile north of Mason Pass (see Fig. 1) and nine miles northwest of Yerington by road, are the upper and lower workings of the Intervalley mine. These are shallow prospects which were never productive and are now idle. Buckskin, about 4½ miles west-northwest of the Ludwig mine, is a prospecting camp, in the vicinity of which some shallow exploration is in progress. Another group of prospects lies in the low hills from four to five miles southeast of Yerington. Among these the Blue Jay, with a 450-ft. shaft, and the Yerington, 412 ft. deep, are the most important. The latter only was in operation in 1908. A mile east of the Blue Jay is the Bradley, about 100 ft. deep, and a mile south of this mine is the Black Rock, with still less development. No work was in progress at either place at the time of visit.

The copper deposits near Yerington are of three kinds—(1) irregular bodies formed by metasomatic replacement of limestone and genetically associated with metamorphism of a kind usually attributed to the contact action of intrusive rock, (2) metasomatic vein deposits in altered limestone, and (3) metasomatic vein deposits in granodiorite.

The deposits of the first class are exemplified by those of the Bluestone, Mason Valley, Malachite, McConnell, Western Nevada, and Nevada-Douglas mines. The original sulphides of these ores are pyrite and chalcopyrite in various proportions. The gangue minerals are pyroxene, amphibole, epidote, garnet, and calcite. The proportions of these also vary widely in different deposits. The tenor of these primary ores is generally low; probably no masses of large size average over 3% in copper. The largest and richest body of such ore that has been at all satisfactorily blocked out is that of the Bluestone mine, which is about 300 ft. long and of approximately the same width and depth. The oxidation of these orebodies has not been extensive and appears to have penetrated deepest in the Mason Valley mine. There has been no important enrichment through the deposition of chalcocite or other secondary sulphides, though some of the oxidized ore is of high grade. Although these deposits are of a character usually associated with contact metamorphism they are not closely related to igneous contacts. Those nearest the granodiorite owe their present proximity to that rock to faulting. Consequently they cannot be regarded as typical contact-metamorphic deposits, although they are believed to belong in that general class and to be genetically connected with the granodioritic intrusion.

The only important deposit of the second class is the Ludwig orebody, in which the vein is composed mainly of coarsely crystalline calcite carrying some garnet with pyrite and chalcopyrite. Oxidation in this deposit has extended to a depth of about 500 ft. and has produced ore of shipping grade. At the base of the oxidized zone there has been some chalcocitic enrichment. The occurrence of garnet in the vein material links this deposit with those of the first group, but the fissuring and veining probably took place after the limestone had been considerably metamorphosed.

The deposits of the third class include those of the Intervalley, Blue Jay, Yerington, Bradley, and Black Rock mines or prospects. They are characterized by the development of pyrite with subordinate chalcopyrite in granodiorite or monzonite along zones of fissuring. In two of them, the Intervalley and Black Rock, there has been some filling of open spaces, but in the others the sulphides have developed within the rock alongside the narrow fissures that served as channels for the depositing solutions. No thorough study of the action of these solutions on the wall-rock has been made. The deposits, however, are believed to represent a stage of mineralization later

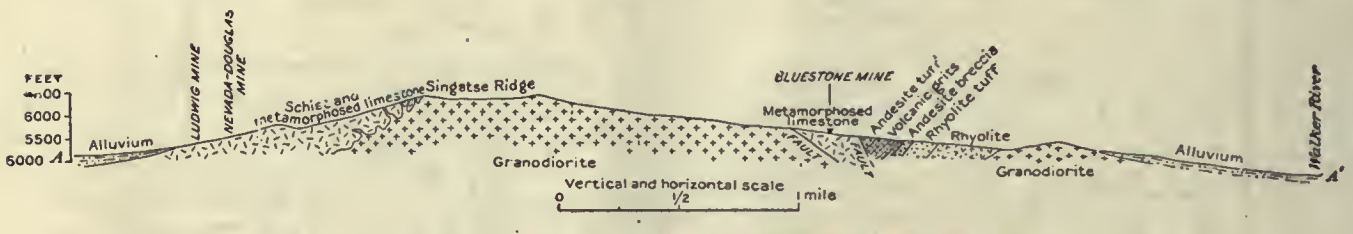

Fig. 2. Generalized Geologic Section Across Singatse Ridge Along Line A-A'.

than those in which the deposits of the first and second classes were formed. The economic importance of the deposits of the third class is as yet unproved.

The total quantity of oxidized ore exposed in the district is small and there is no indication of any extensive sulphide enrichment. The quantity of gold or silver in the ores is practically negligible. The future of the mines depends on the working of low-grade primary deposits. The conditions are in some respects favorable for cheap mining and concentrating; a railroad could be constructed from Wabuska along Walker river with little difficulty, water is more plentiful than in most other parts of Nevada, and many agricultural products can be grown in Mason valley. On the other hand, water, tailing, and smelting fumes are subjects concerning which miners and farmers usually find agreement difficult.

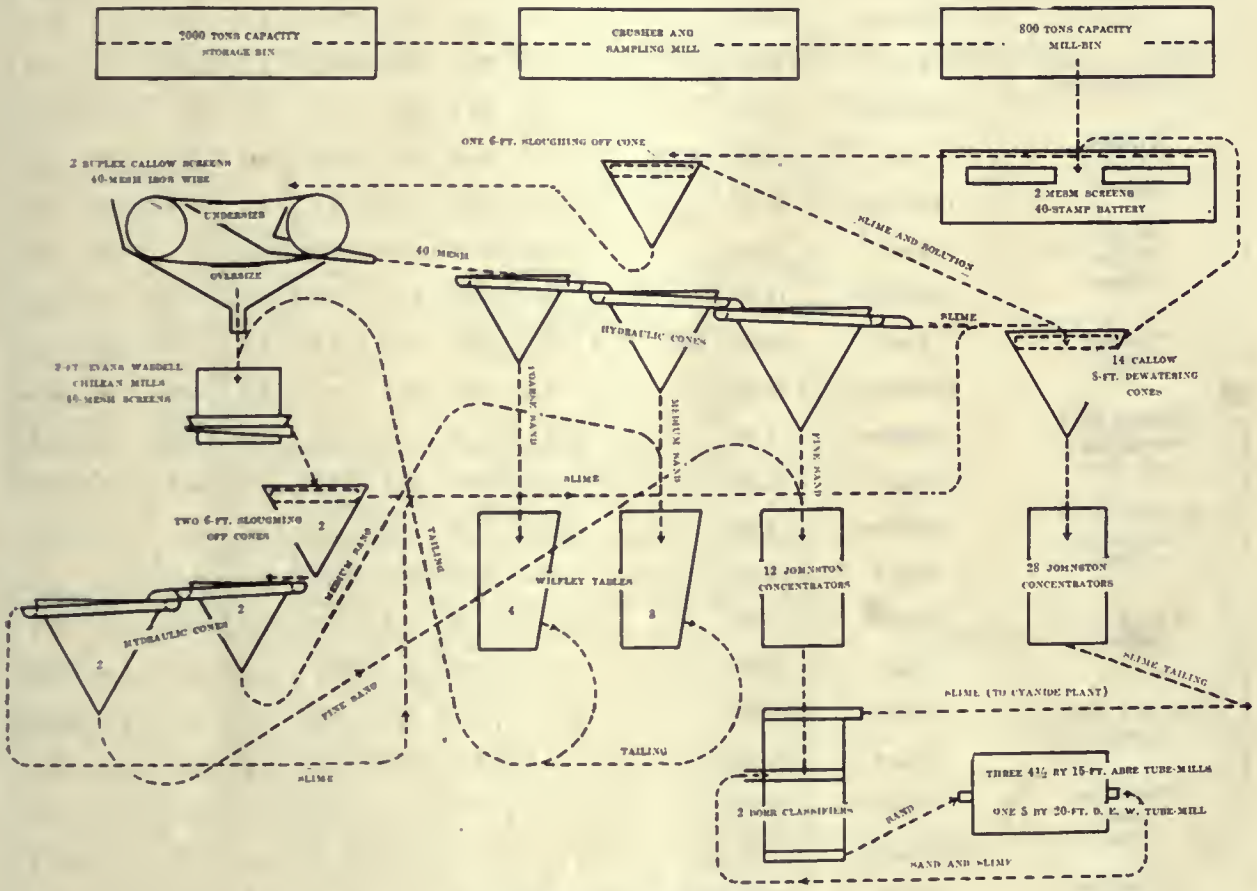
Gas-producer plants, according to R. H. Fernald, as a whole are giving remarkable satisfaction in view of the brief period of development. The most serious difficulty seems to arise from the lack of competent operators to run the plants, though there are many more competent operators today than three years ago. The situation regarding misrepresentations and misunderstandings resulting from incompetent salesmen has with the stronger companies greatly improved, and there is less trouble due to manufacturers neglecting plants that have been installed and paid for. The situation has changed decidedly for the better within the last few years.

Grinding Tests at Pachuca.

By V. B. Sherrod.

*In the past year a great deal of investigation has been done at the Guerrero mill, Pachuca, particularly in the direction of pulp classification and in ascertaining the efficiency of tube-mill work under varying conditions, and I have prepared the following notes in the hope that they will serve to illustrate some of the features of importance disclosed in these investigations.

The flow-sheet illustrates clearly the sequence of the various operations and is self-explanatory.



Flow Sheet at Guerrero Mill.

The screen analysis of samples (table No. 2), shows the average screen, or grading-analyses of several sets of samples taken during the month of July, 1909, at the Guerrero mill, the various products at each step being carefully sampled. A study of the figures will show some interesting features. Special attention might be called to the work of the Callow screens which at 100-ft. belt travel per minute (a high speed), when equipped with 30-mesh No. 33 steel wire (the purpose being to separate as undersize all material that can be made to pass a 40-mesh laboratory screen), gives an oversize 92% of which remains on a 40-mesh screen and 96.5% remains on a 60-mesh screen. At the same time an undersize is sent to the hydraulic cones, 9½% of which passes a 40-mesh, said product containing practically all of the liberated mineral. The effect of this system is seen in the enormously wide streak of mineral on the first three Wilfley tables, which really receive as feed a product that has once been concentrated by the Callow screens and once by the hydraulic cones following these.

Another feature of interest to concentrator men, is the analysis of the product of the Chilean mills, 4% of which remains on a 40-mesh screen and 32.4% of which passes a 200-mesh screen, notwithstanding that a 30-mesh 'ton cap' screen is used in the mills. The discharge through these screens is kept up to the maximum, a heavy splash being used, but all material coarser than 60-mesh is, so far as possible, cut out in the first hydraulic classifiers following these mills and sent back to the Wilfley tables, where it joins the oversize from the Callow screens and returns again to the Chilean mills.

Another feature of the grinding at the Guerrero mill is the fineness of the tube-mill feed, only 7% of which remains on a 60-mesh screen. This is, of course, absolutely against high tube-mill tonnage, but is justified by the necessity for the most careful possible concentration, which means, on these ores, pretty fine grinding, in stages, and careful elimination of mineral after each step and before the tube-mills get a chance to slime the mineral. The apparently low efficiency of the tube-mills receiving such feed, in comparison with the Loreto mill of the same company, for instance, in which a much simpler flow-sheet is in use, is principally due to the fact that all of the easily slimed portion of the ore has been made to pass a 200-mesh screen during its repeated passage through the Waddell mills, leaving for the tube-mills nothing but the most refractory portion to grind.

The tables herewith are made from sampling done at Loreto mill on various dates and do not furnish absolute comparison with the performance of the Waddell mills above mentioned, on account of the difference in the grinding system employed and also because the ores fed to these mills are much more friable than those ground in the Guerrero mill. The object of the test was to determine the most efficient feed for the tube-mills and to furnish comparisons between the tube-mills differing from each other in make and leading dimensions, especially in diameter.

The samples from which the analyses were obtained were taken in sets. For obvious reasons, such as daily variations in the character of the ore, too close comparisons should not be made between analyses of samples of different sets. Some sets of samples must also be eliminated from any comparisons whatever, because conditions changed so frequently during the two or three hours consumed by the tests that determination of kilos per minute of solids fed to mill, percentage of solids, and the like, are not accurate. Such tests are indicated by marginal notes. Despite these disabilities, however, it was possible to collect many valuable data.

The determination of the most favorable feed for horse-power efficiency was naturally the first consideration, with special reference to the percentage of solids in the feed and the kilos of dry feed per minute for each different mill. A little study of the tables leaves no doubt as to these points, except in the case of No. 4 mill (D. E. W. Co., 5 by 20 ft.), wherein the value of the tests was practically destroyed by the variations of feed above referred to. Therefore, the tests on this mill are given for what they are worth, demonstrating as they do that the horse-power efficiency of the mill does not increase with the quantity of dry feed up to an undetermined point. Briefly the conclusions which may be safely drawn from the series of tests are as follows: (1) That the grinding efficiency increases with the percentage of solids in the feed up to about 55 or 60%. (2) That the grinding efficiency increases with the quantity of ore fed per minute to a point which varies with the dimensions of the mill, and that beyond this point capacity is not gained and within reasonable limits there is no loss except that due to the return to the mill of an excess of oversize. The limit of profitable feed varies with the character of the pulp, and it is only possible to determine this limit for any mill by special experiment with the ores for which the mill is intended.

At the Loreto mill the profitable feed for the 4 by 18-ft. mill was apparently 80 kilos of solids per minute, or at the rate of 115 metrical tons per 24 hours, although heavier feed did not reduce the efficiency of the mill. The limit for the two 4 ft. 6 in. by 15-ft. mills was not proved, but is apparently somewhat lower than the correct feed for No. 1, and is probably due to the fact that they are 3 ft. shorter, which reduces the capacity somewhat, and they have a greater diamater, which tends toward a reduction of their horse-power efficiency.

This statement as to horse-power efficiency is not absolutely proved by the above tests, but in every case the efficiency has been lower in mills of greater diameter except one in which the small mill did not

have more than about 60% of its most economical feed.

The 5 by 20-ft. mill (which is mechanically the best built one), has shown in every comparative test a lower grinding efficiency than the smaller mills, but it would not be fair to look upon this deduction as final, owing to reasonable doubt as to the accuracy of determination of quantities.

MINERAL RELATIONS FROM THE LABORATORY VIEWPOINT.

By Arthur L. Day.

*The remarkable contributions which have been made to our knowledge of aqueous solutions since the formulation of the science of physical chemistry leave little doubt that its generalizations can be applied with equal success to the study of rock formation; but the effort to make the application has brought us face to face with the fact that the problem of rock formation is of much broader scope, and its phenomena far more intricate, than ever was imagined in the years when the first plans for laboratory work in the service of geology were made. This has had one conspicuous consequence. Most of the work done in the earlier years of laboratory experiment cannot now be used to aid in the application of the new theories to mineral solutions. The first effect of this conclusion is to emphasize the necessity for widening our viewpoint to meet the increased scope which physical chemistry has imposed upon the study of mineral and rock formation from the magma, and the second, to compel us to revise our experimental methods so that the number of unknown factors will not outweigh the known and so prevent their intelligent interpretation and eventual application to geology. It is also necessary to recognize more explicitly the physical conditions affecting the problem upon its quantitative side. For example, we cannot profitably continue to determine melting and solidifying points of natural minerals, and still less of complicated rocks, knowing that the addition of a small quantity of impurity almost always lowers a mineral melting point considerably, and knowing also that no mineral type occurring in nature is free from such impurities. We cannot continue to observe melting temperatures by watching for the moment when the mineral begins to sag and run, knowing that in many most important minerals deformation does not occur until long after melting is over. We cannot continue to ascribe individuality and characteristic properties to mineral glasses knowing that they represent an unstable and undefined condition which may persist for months or years, or even for geologic time, without reaching equilibrium. At best, physical chemistry encounters this difficulty in considering both the natural minerals and the natural rocks; individual minerals do not occur in nature in uniform types, but are somewhat variable solid solutions with many minor ingredients; so too with the rocks we often find that equilibrium is not reached during the entire process of natural formation.

*Abstract of paper presented at the Boston meeting of the Geological Society of America.

Santa Clara River Placers.

Written for the Mining and Scientific Press
.By Claude E. Jamison.

The Santa Clara river placers are situated about 40 miles northwest of Los Angeles, on the north side of the little Santa Clara river, in Los Angeles and Ventura counties, California, in the Santa Barbara National Forest. The district is of particular interest on account of having been the scene of the first gold discovery in California. Although it is the general belief that the first discovery of gold was made near Sutter's Fort, that honor belongs to southern California, as is shown in the following extract taken from Hittel's 'History of California': "It was in Alvarado's time, and about March, 1842, that gold was first discovered in Alta California. * * * * In 1841, Andrés Castillero, the same person who afterwards discovered the New Almaden quicksilver mine in Santa Clara county, while traveling from Los Angeles to Monterey, found near the Santa Clara river a number of water-worn pebbles, which he gathered up and carried with him to Santa Barbara. He there exhibited them, said they were a peculiar species of iron pyrite, and declared that, according to Mexican miners wherever they were found, there was a likelihood of gold being also found. A ranchero, named Francisco Lopez, who was living on Piru creek, a branch of the Santa Clara river, but happened at the time to be at Santa Barbara, heard Castillero's statement and examined his specimens. Some months afterwards, having returned home, he went out on a search for strayed cattle. At noon, when he dismounted from his horse for the purpose of resting, he observed a few wild onions growing near where he lay. He pulled them up, and in doing so noticed the same kind of pebbles as those to which Castillero had called his attention. Remembering what Castillero had said about them, he took up a handful of earth and, upon carefully examining it, discovered gold. The news of the discovery, the exact location of which was a place called San Francisquito, about 35 miles northwest of Los Angeles, soon spread, and in a few weeks a good many persons were engaged in washing and winnowing the sands and earth in search of gold. The auriferous fields were found to extend from a point on the Santa Clara river, about 15 or 20 miles above its mouth, over all the country drained by its upper waters and thence easterly to Mount San Bernardino. On May 14, 1842, Alvarado wrote to the prefect of the district, reproving him for not having given official notice of the discovery, and directing him to gather and forward an account of all circumstances of interest relating to the gold for transmission to the supreme government. From that time to this day, there has been more or less working of these mines; but no placers of very great richness have been found, and none to compare with those afterwards discovered on the tributaries of the Sacramento and San Joaquin. Taking the whole country together, however, from the Santa Clara river to Mount San Bernardino, a very considerable quantity of gold has

been extracted. During the first year, though the methods of working were exceedingly rude, it is said that Lopez and a partner, named Charles Baree, with a company of Sonorians, took out over $8000. In November, 1842, a package of about 18 oz. of the gold was sent by Abel Stearns to the United States mint at Philadelphia, and upon assay it was found to be worth a little over $344."

The State Mineralogist in his report for 1888 states that, "the gravel averages 90 ft. in depth. According to the tests made with a dry washer, the gravel, it is stated, gave an average yield of 36c. of gold per cubic yard. Of course the dry washer does not separate the gold from the clay and lumpy portions of gravel."

In the fall of 1908 I visited this district and made a preliminary examination, spending some two months on the ground. The gravels, belonging to the Miocene period, are found at an elevation of about 1500 ft. above sea-level, covering the low hills north of the Santa Clara valley, and occupying an area about 20 miles in length by 10 in width. Placer gold, ranging in size from microscopic colors to nuggets of 5 dwt. or more, is found almost universally distributed over the entire area. The gold content is probably due to the innumerable quartz stringers found in the granites and schists of the northern part of Los Angeles county.

The results of a large number of samples showed the average gold content to be 28c. per cubic yard, and the depth to be at places as great as 100 ft., but, although the quantity of gravel in the entire district is considerable, the average depth is not sufficient for successful hydraulicking.

As fully one-third of the original gravels have been eroded and carried down, presumably to be redeposited in the valleys below, it was natural to conclude that in these valleys good dredging ground would be found. Other conditions, such as climate, bedrock, proximity to railway and power, and the like, were ideal. However, before proceeding further, I learned that the valleys had been drilled some time previously, and that the average gold-content of the gravels had been found to be less than 1c. per cubic yard. The reason for this upsetting of theory is plainly shown in Piru valley, in the western portion of the district. This valley, which a few years ago was a gravel-filled channel, is now a mass of large boulders with little or no sand or gravel. The country is subject to occasional very heavy rains, or cloud-bursts, which completely scour out the valleys, carrying everything but the heaviest boulders down to the Santa Clara river, where, becoming mixed with the barren sands of that valley, the average value is reduced too low for profitable working.

For a number of years these placers have been a source of revenue to some of the residents of that section, not, however, by sluicing or washing, but by bringing them to the attention of capitalists seeking dredging ground, obtaining a small cash payment as 'earnest money', and employment for teams until the true value of the ground is determined and the examination discontinued. A search for a new 'sucker' is then begun, and, backed by the report of the State Mineralogist, quoted above, and by numerous affidavits of Mexican 'gambocinos', it is soon successful. The results of former examinations, and even the fact that examinations had been made, are carefully concealed.

All over the district the rusting remnants of gold-saving machinery bear mute testimony to the number of attempts which have been made to work the gravels. In Texas canyon is a reservoir built by a company with an ex-governor of California at its head. In Dry canyon are the sluices, bucket elevator, and 'black sand savers' installed by the late Frederick H. Rindge, while on a hill nearby are a number of patent gold-savers. In Tapia canyon a steam scraper was installed and about 500 cu. yd. of dirt handled, with a recovery of $21 and an expenditure of $25,000, before the machine was removed. In Santa Feliciana canyon about 5000 yards of gravel has been hydraulicked and a number of drifts driven on bedrock. This canyon is in the richest portion of the district. Much of the gravel on bedrock shows a gold-content of from 75c. to $3 per yard. However, it is to be presumed that operations were carried on at a loss, as no work has been done there for years, although the 'oldest inhabitants' solemnly told me that these workings had produced more than $100,000.

In the spring the smaller gulches are worked by the Mexicans who manage to clean up about $1 per day per man. Three miners working in Deadman's canyon, at the time of my visit, were cleaning up about $20 per day, or about $8 per yard, from 18 in. of gravel on bedrock, while I obtained results as high as $30 per cubic yard in some of the smaller gulches. However, these favored spots occupy only an insignificant area and are not often found. A preliminary examination shows the district to be very inviting, but it will not stand a rigid investigation.

The Mancayan copper deposit is the largest in the Far East. It is in Lepanto, Philippine Islands. The deposits were worked by the Spaniards and over a thousand tons of copper was taken out yearly at one time. After American occupation the smelter was burned by the Insurgents and active work was not resumed. American prospectors have occupied the property and the Lepanto Mining Co. has been interested in an option on the property. A contract was recently signed with a German company under which the Lepanto Mining Co. bonded the property under its control, including 11 claims and fractions, for a period of six to nine months. Experts are now investigating the property, and it is not improbable that a deal will be closed for the purchase and development of the group. Negotiations are also being carried on with other owners of property at Mancayan with a view to including adjacent groups. The deposits are valuable and have been most favorably reported upon several times. Transportation to the coast seems to be the greatest item of expense to be considered, but there is reason to believe that the large body of ore of high grade available would more than warrant the investment.—*Far Eastern Review.*

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Metallurgical Progress in Colorado.

The Editor:

Sir—I am sorry the management of the Modern Smelting & Refining Co., of Denver, consider the remarks in my article on 'Metallurgical Progress in Colorado', published in the MINING AND SCIENTIFIC PRESS, of January 1, as "obviously unfair." I do not hold a brief for anyone; my information came from a person familiar with the 'Modern Smelter,' and the practice prevailing there toward the close of the last year. I believe that he, equally with myself, desires to be fair and impartial. The point that I tried to make was that pyritic smelting in Colorado had a fair trial and failed everywhere except as noted by me, and, in that solitary instance of possible success, the smelter had large mines behind it that may have been an important factor in the case. Be that as it may, the statement that "we use 4% less coke, and make slags 8% higher in silica, than any plant now operating in Colorado," has a very familiar appearance, quite pyritic in fact, yet it tells but a small part of the story. Fuel is needed to heat the blast, silicious ores are not very plentiful in Colorado just now, and the final matte, after its various passages through the furnace for enrichment (and incidentally loss of precious metals), is not quite desirable from a monetary point of view, as is base bullion, the product of one smelting. Thus we come to the crux of the whole matter, the concentration of the precious metals in a product ready for the refinery. I hold that the lead base will give the higher extraction at the least cost, and, under the conditions that now obtain in Colorado, must prevail. An argument in favor of pyritic smelting might be predicated on a preliminary treatment or concentration of low-grade ore, at or near the mines, but to establish a pyritic smelter in Denver, drawing half of its supply of undesirable ore from Redcliff, Leadville, and other distant points in the State, does not appeal to me as sound business.

The Modern Smelting & Refining Co. is to be congratulated on the *slag* made "for days" (I hope continuously) "carrying only a trace of gold, 0.25 oz. silver and 0.05% copper", but at what cost is not stated, yet the cost is equally as important as the saving. A sailor cannot determine his position by longitude alone, nor can a metallurgist proclaim unqualified success on a few slag assays. Smelter campaigns need to be for much longer periods than a few days. Dust loss, and the recovery and working up of fine dust, is a large item of cost in pyritic smelting. Cases are known where it ate up all the profits accruing from the major operation of the plant. One thing, however, is certain, the company that can smelt cheapest and settle promptly for its ores need not fear the alleged "strangle hold" of the most powerful smelting interest in this or any other State, much less fair criticism in the technical press. Permit me to say in conclusion that I have no interest in or connection with any smelter in Colorado, but in the general interest of mining I would be pleased to see the successful establishment of a process that would reduce the treatment-charges and enable the handling of lower grade ores at a profit to the miner; but the first paragraph of the communication of the Modern Smelter company in your issue of February 5, is not the kind of talk that successful or even resourceful competition has need to resort to.

PHILIP H. ARGALL.

Pueblo, Colorado, February 14.

Disposal of Government Oil Lands.

The Editor:

Sir—It is gratifying to have the absurdity of the application of the placer mining laws to oil lands brought out by Mr. Ballinger's report as Secretary of the Interior and the statement of Mr. C. W. Hayes. It is to be hoped that the unfortunate legal misfit will be replaced soon by Congress. The matter is, however, an exceedingly difficult one and the elaboration of a proper law is a task which will demand a great deal of study. I have had experience in taking oil placer mining claims and with the regulations promulgated by the Department of the Interior for the leasing of oil lands in Oklahoma, and venture to suggest a remedy. The greatest difficulty which Congress will meet is the fact that the law must cover conditions which are very dissimilar. It is important to adopt a system which will work for the conservation of oil in certain regions where overproduction now prevails, and at the same time give encouragement to oil prospecting in districts far from producing fields where petroleum products are abnormally high in price. The only way to meet this difficulty is to recognize different classes of petroleum lands and to adopt different regulations for each.

It is not to the public interest to encourage the production of oil at present in California within a hundred miles of developed pools, since so much oil is being produced that it is necessary to store the surplus with a consequent loss of the more volatile parts. For such lands the Government may properly adopt stringent regulations which will bring it as much revenue from the sale of the oil as possible. On the other hand in all of the other Western States, except Kansas, Oklahoma, and Texas, petroleum products are in great demand. This necessitates transportation of oil over great distances and results in high prices, although there can be no doubt that in the State of Wyoming, at least, proper encouragement of prospecting would soon make this an exporting State. Since this would be to the general advantage of the people, it would seem desirable to adopt regulations for such lands which would be very encouraging to the prospector.

In order to avoid too sharp a distinction it would be desirable to have an intermediate class. The proposed classification is as follows:

Class A. Including all public lands within 100

miles of a field having a daily average production of 1000 barrels. Applications should be received for tracts of 320 acres or less. Royalty, 10%, payable upon the production of a well, after it has produced 2000 bbl. of oil.

Class B. Including lands more than 100 miles from a field having a daily average of 1000 bbl. per day, but within five miles of a producing well. Applications should be received for 640 acres or less. No royalty unless there is competitive bidding.

Class C. Including lands more than 100 miles from fields producing 1000 bbl. per day, and farther than five miles from a producing well. Applications should be received for tracts of 2560 acres (four sections) or less. No royalty unless there is competition.

Applications to be made to Commissioners of the Land Office and held in the confidential files one month. If, at the end of this time no other application has been made, the lease to be awarded to the applicant, provided a bond for $500 be filed within 15 days and a well drilled upon the tract within six months to a depth of 2000 ft., or to such depth as may be prescribed by the United States Geological Survey, unless a producing well is obtained at a less depth. If one or more others apply within the month, the several applicants, and these only, shall be asked to submit bids on the amount of royalty which they will offer on the production of oil or gas after 2000 bbl. of oil, or one month's flow of gas has been produced from each well. The lease to be recorded with the appropriate county clerk or recorder of deeds, as also notice of forfeiture if cancelled. If at the end of six months the well has not been completed, the bond to be forfeited to the Government and the land to be open for application.

The oil or gas rights on all Government land should be henceforth retained to be leased in this manner. These leases involve the oil and gas rights and give no rights to the surface except such privileges as to entry and use as are necessary for operation. Where a well results in discovery of minerals of value other than oil or gas, and which were not previously known, the operator shall be given 30 days in which to locate a mining claim. The whole procedure must be described with great care and detail with special reference to the ambiguities which have arisen in the interpretation of the mining laws.

It is believed that these regulations would have the effect of: (1) Restricting the profits of mere speculators at the expense of bona fide prospectors. (2) It would encourage oil production in regions where it is needed and not encourage it in districts where overproduction prevails, although permitting a gradual development there by genuine operators. (3) The Government would receive a considerable revenue from the oil without improperly restricting the oil development. (4) Petroleum would be conserved according to the best standards; namely, of bringing oil into use as needed with the avoidance of wasteful overproduction.

It is to be hoped that the Department of the Interior in its zeal to accomplish conservation will not make the conditions of prospecting so onerous that wild catting in the Rocky Mountain States will be prevented. There is an enormous area which should be tested, and suitable inducements must be held out. The conservation of petroleum for the future needs of the navy and country alike had best be accomplished by a leasing system which will restrict local overproduction rather than by the withdrawal of any definite tract of land. Such a withdrawal would work injustice to the communities concerned.

The other method of conserving oil for the use of the navy suggested by Mr. Lockwood, namely, that of storing mid-continent oil in tanks because it is now so cheap, is far too wasteful. The mid-continent oil contains a considerable percentage of the lighter products which must be separated from it before it could be safely used on battleships, and the storage of such oil for long periods would result in too serious a waste, from the evaporation of these valuable products.

R. H. JOHNSON.

Bartlesville, Oklahoma, January 19.

English in Our Technical Journals.

The Editor:

Sir—In one column the editor of the technical journal asks the operator for practical contributions and in another he ridicules the literary ability of those who comply. Mr. Strange, in his letter published in your issue of November 13, caps the climax by criticising the articles as they appear. In other words, he scorns the efforts of the editor as well as those who contribute. Mr. Strange said, "Surely a set of men cannot claim to be fitted for any profession until they are thoroughly prepared to express themselves." Only a supreme egotism can class mining, smelting, cyaniding, etc., other than as mechanical trades. Furthermore, "a set of men can be well fitted" to do many things with hands and brains without being able to express their thoughts or describe results in faultless English. As I understand it, there is a man—a mere grammar sharp—on the staff of the properly equipped technical journal, a drudge who is paid about what a mine mucker earns. This expert word-juggler is supposed to prevent the appearance in print of what Mr. Strange objects to. As regards the responsibility of the editor for the correct appearance of contributions, be assured, sir, that you will lose many correspondents as soon as you begin to publish articles without revising them. Although a contribution is supposed to reach you in proper form, it is your duty to clarify it where necessary. If the subject is one with which the editor is not familiar, he should ask the contributor for an explanation of obscure passages. Usually the man who does things has little time to devote to the continued study of English composition. Conversely, the one who continues dexterous with words may be of limited capacity in other directions. Those who ask for contribution as a matter of policy should ignore the shortcomings of those who comply, instead of frightening them with demands for perfection in orthography, syntax, and grammar. As well demand type-setting skill.

MARK R. LAMB.

Milwaukee, Wisconsin, February 7.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Colorado mining laws are not published separately. They will be found in the Revised Statutes of 1909. 'Morrison's Mining Rights' contains the principal mining laws of various States, including not only statutes, but judge-made law.

Chrome ore is used extensively in the open-hearth steel process as lining for the floor of the ports, especially in basic-steel work, and in the more exposed places where slag is liable to lodge and corrode. It was also applied to copper furnaces, but has not come into very general use. The attempt to make crushed chromite into bricks, which has met with partial success, would more effectually solve the problem for copper reverberatory work.

Use of steel in mine timbering can be no longer considered as an experiment. It is a material of construction tested under all kinds of conditions and service, is adapted to all forms of construction, is easy to obtain, convenient to fabricate and erect, and economical in all directions, and its long life, under all conditions of temperature, moisture, and stress, compensates for the increased first cost of its installation as compared with wood.

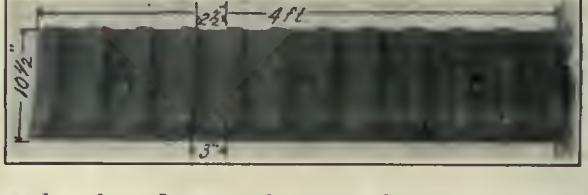
Wells drilled into water-bearing beds should carry the inner pipe entirely through them to some hard stratum lying next below, and sufficiently far into that stratum to hold the pipe rigidly. As it is needful to have the part of the pipe in the water bearing strata perforated, to admit the water, this portion of the pipe should be extra heavy. This pipe should pass through the upper casing so that it may be withdrawn for renewal or repair when necessary. If galvanized, the life of this pipe should be very long.

Titanium gives promise of extended use in steel and cast-iron. In steel it is ordinarily introduced as ferro-titanium, with from 10 to 20% tatanium, sufficient to make up approximately 0.1% of the steel. Rails treated thus show great resistance to wear. Gray cast-iron is also made harder by such treatment. Cupro-titanium is manufactured for use in bronze and other castings containing copper, making them much tougher. Titaniferous ore is mined chiefly in New York, Minnesota, and Wyoming; and a large deposit of rutile (titanium dioxide) is worked in Nelson county, Virginia.

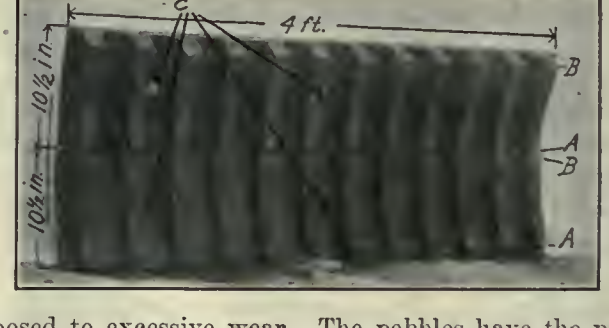
Blast-furnace capacity, other factors remaining unchanged, varies with the quantity of air delivered into it, or, with the same tuyere area, the smelting speed of the furnace varies directly with the blast-pressure. Not only is this so, but the successful operation of the furnace depends upon a correct adjustment between the quantity of air and the fuel on the charge. Therefore it is important to maintain a uniform delivery of air, which means a narrow range of fluctuation of the blast-pressure. Granting that the character and height of the charge in the furnace are maintained constant, this desired uniformity in air-pressure is maintained by properly governed blower-engine speed and by control of the air temperature. The latter is now accomplished successfully by the Gayley apparatus for iron blast-furnaces, but has not been adapted as yet to copper smelters.

Claim A is a valid claim which becomes subject to adverse location by reason of failure to perform assessment work during the year 1909. On December 22, 1909, claim B is located across claim A by parties other than the owners of A. On January 1, 1910, still other parties re-locate claim A. The area in conflict belongs to those who re-located claim A, for this area was on December 22, 1909, and up to the end of the year 1909, embraced in the valid and existing original location A. No valid rights could be acquired by adverse locators to any portion of claim A until the beginning of the new year, 1910.

The tube-mill liner illustrated herewith, used by Cooper Shapley at the mill of the Santa Natalia Mining & Milling Co., Guanajuato, Mexico, will be of interest. As shown, the ribs of the liner encircle the tube-mill, being at right angles to the axis of rotation. The ribs on each plate are cast with a slight taper from one side of the plate to the other, thus leaving



a wedge-shaped space between for the pebbles to catch and wedge themselves firmly into place. The plates are cast in such a manner that the butt end *B* of one rib comes against the pointed end *A* of the rib on the adjoining plate, thus leaving no points ex-



posed to excessive wear. The pebbles have the peculiarity of catching in this liner with their shorter diameter between the ribs, thus leaving a third or more of their bulk projecting above, exposing an exceptionally rough surface to the loose pebbles in the mill, as well as serving a further protection for the liners themselves. With this arrangement of rib, 26% more rock-lining can be obtained, and the lining itself weighs 30% less than the liners formerly used. These liners have been in use for six months, employing mine rock for tube-mill filling, and the wear cannot be detected. The liners are placed in the mill in such a manner as to use the wedge-space between the ribs to the best advantage for picking up and holding the pebbles. Bolt holes are shown by arrows from the letter *C*.

Special Correspondence.

SYDNEY, N. S. W.

Mineral Industry for 1909.—Broken Hill Mines and Processes. — Electrolytic Copper Refinery.—Mount Lyell.

Although the first discovery of gold in Australia was made in New South Wales as far back as 1851, and although that State had produced, to the end of 1908, not less than 13,258,793 fine ounces of the royal metal, valued at £56,319,736, gold-mining does not occupy the first place in its mineral industries; this is filled by coal, the value of which has been £56,632,254. For many years past, however, New South Wales has been more widely known in the commercial world as a producer of silver-lead ore, and it is a remarkable fact that, although this industry was hardly commenced until well on into the eighties, the value of the output is already considerably beyond £50,000,000, and the yearly production is now, in spite of the low market values of the metals, of far greater importance than the gold output of the State. The silver-lead statistics for the last year do not furnish a fair comparison with other recent years, because industrial troubles at Broken Hill, the centre of the industry, laid some of the principal mines idle for several months, and the largest producer of all, the Proprietary company, has not been working throughout the whole year. But in 1908 the silver (ingots and matte) amounted to 2,490,163 oz., valued at £253,920, and the silver-lead ore and concentrate to 358,729¾ tons, valued at £3,658,632. The exports for the first nine months of 1909 were as follows: silver (ingots and matte), 1,279,830 oz., valued at £125,642; silver-lead concentrate, etc., 170,947 tons, £984,187; lead in matte, 11,867 tons, £142,580; making a total value of £1,252,409. With respect to gold, since 1894, with the exception of 1901, '02, '08, and '09, the annual output has exceeded £1,000,000; in 1908 the amount dropped to £954,854, and for the first eleven months of 1909 it was only £777,451, as compared with £862,426 for the corresponding portion of last year. Next in importance ranks the copper output; the value of the product to the end of last year had reached £9,703,215, and although the year 1908 saw a decline, not only in value but also in quantity, the figures for 1909 when completed will probably show a larger production than usual. In 1907 copper ingots, matte, ore, etc., amounted to 10,098 tons, valued at £1,444,533, but in 1908 only 9071 tons was produced, and this, on account of low prices, brought only £999,376, whereas during the first nine months of last year the production was 9684 tons, valued at £558,485. The total production of tin and tin ore between 1872 and 1908 was valued at £8,243,261, the quantity being, ingots 74,820 tons, and ore 22,509 tons. The output for 1909 will doubtless show a marked improvement on the annual yields of the past twenty years, for during the first nine months it reached 2039 tons, which, at the same rate, will give over 2700 tons in ingots and ore for the year, an amount not reached since 1887 when the figures were 2917 tons. Of recent years the production of pig iron has received a fresh impetus, and whereas in 1900 only 7737 tons was produced, that being the highest figure to that date, the quantity reached close upon 30,000 tons in 1907, and 40,207 tons in 1908. Considering that the aggregate output of pig iron for the State during upward of thirty years has only reached 198,165 tons, the fact that upward of one-fifth of that amount was produced in one year, and upward of one-third in two years, indicates that the industry is in a fair way to increase. Zinc also should be mentioned as a metal which has of late years been produced on an increasing scale, mainly in the form of concentrate; in 1904 the production amounted to only 57,602 tons, but in 1908 it had reached 275,932 tons, or, including spelter, 276,720 tons, valued at £600,883. Among the minor mineral industries are the production of noble opal, amounting in 1908 to £41,800, and in 1907 to £79,000; portland cement, 1908, £184,400, 1907, £144,548; wolfram, scheelite, antimony, bismuth, molybdenum, and numerous other metals and ores which have a commercial value but which have not yet been produced in sufficient quantities to be commercially important.

In regard to the position and prospects of the various silver-lead mines at Broken Hill it need only be said that in most cases they are developing satisfactorily and give promise of yielding up their treasure for many years to come. The fly in the ointment, however, is that the Broken Hill Proprietary mine is practically an institution of the past, and the same may also be said in regard to the Broken Hill Block 10 Co. Not that the Broken Hill Proprietary has been wholly depleted of its ore—far from it—but under the high wage-system which prevails it is impossible to carry on operations at the mine at a profit. The result is that the company has been looking around and has practically acquired a new mine which it is prospecting. It must not be reckoned that the Broken Hill Proprietary will be a back number if this new mine does not turn out well, for they have gradually built up an industrial concern—the treatment of concentrate and the manufacture of spelter and the production of sulphuric acid—which must return handsome profits to the shareholders. In regard to

Eastern Australia.

the Broken Hill Block 10 they have had to go farther afield for a basis for a fresh enterprise, and recently they purchased a silver-lead mine at Zeehan, Tasmania, to which place it is proposed to transfer operations. A development of a highly satisfactory nature has occurred at the Broken Hill South mine. The diamond-drill which started boring west at a point 430 ft. south on the No. 4 level has cut a lode which is supposed to be identical with that being followed in the north drift from the Block 5 shaft. The drill after boring west passed through 15 ft. of ore assaying 9% lead, 2 oz. silver, and 20% zinc. If this body of ore is the same that is cut in Block 5 shaft it will give the company a fine lot of ore. The Central mine of the Sulphide Corporation is at present producing on a large scale, and it is only with difficulty that the dispatch of material is being maintained at such a rate as to enable the big stocks of products on hand to be reduced to any appreciable extent.

Metallurgically there have not been many important additions to the treatment processes employed on the Hill. The new mill of the Broken Hill North will be the best in the district; three units have been completed, and are giving satisfaction. The principal feature of the machinery is the Weis-Meredith slime table, the design of employees at the mine. Mr. Weis is the general manager and Mr. Meredith

mill superintendent. The table, a description of which will be given on another occasion, is installed as a standard in the mill, and they have also been placed in other mills on the Hill.

The treatment of zinc-bearing tailing is now a big industry on Broken Hill. Altogether there are no fewer than five plants using flotation and vacuum processes. The Broken Hill Proprietary, treating 8000 tons of tailing per week, is employing the Potter-Delprat flotation process under license; the Sulphide Corporation (Mineral Separation Co.) is using a combination of Ballot-Cattermole and Sulman flotation, and treating 7000 tons of tailing per week; the Zinc Corporation, working the Elmore vacuum process, is putting through 4500 tons per week; De Bavay Co., using a modification of the De Bavay flotation patent, is operating on 1000 tons per week; the British Broken Hill Co. is erecting an Elmore plant; Block 10 proposes installing a similar plant, and the Broken Hill Block 14 has made arrangements for the installation of a Murex magnetic plant. Whether the latter will be carried out is greatly doubted in Australian mining circles.

Electrolytic copper-refining plants are in operation at the Great Cobar, Ltd., and at the Electrolytic Refining & Smelting Co. of Australia, Port Kembla, which is controlled by the Mount Morgan G. M. Co. of Queensland. The multiple system is in use at the various plants. At the Port Kembla plant, where double tanks are used, an adaptation of the three-wire system is employed, a small triangular copper piece being used as the centre conductor.

The two outstanding prizes in connection with Tasmanian mining are the Mount Lyell Mining & Railway Co. (copper) and the Mount Bischoff Tin Mining Co. (tin). The former has just closed another successful year and the outlook for the future is one of great promise. The parent mine of the company—it must be remembered they have two—is still providing a large quantity of low-grade ore, and though the copper content is low the ore is rich in sulphur and is being profitably converted into sulphuric acid for use in connection with the manufacture of super-phosphates. Works are now in operation in Victoria and South Australia, and a plant is being erected at Fremantle, Western Australia. The North Lyell mine is turning out riches as depth increases, and the ore at the 1100-ft. level is now of a high grade. As an indication of the success of the company it may be mentioned that the old and present company have distributed between them £2,436,574, assuming that copper maintains a value of £60 per ton for a period long enough to permit of the treatment of the necessary quantity of the Mount Lyell ore, it is evident that further considerable sum will be distributed in the way of dividends. At the Mount Bischoff mine the only important features are that the treatment plant is being duplicated, presumably to double the output, which is now 80 tons per month, and that the mine is being developed most satisfactorily. The numerous other tin, copper, and silver-lead ventures are being worked consistently but their output is not extensive.

TORONTO, CANADA.

Cobalt Shipments. — Gowganda. — Porcupine Development. — Alberta Wild-Cat Oil Companies.

Shipments of ore from Cobalt during January showed a falling off as compared with the output for January, 1909, the total being 2028 tons, as against 2375. Over one-half of last January's shipments was contributed by three mines, Nipissing supplying 384 tons, La Rose, 366, and Drummond, 332 tons. The delay in furnishing cheap electric power is mainly responsible for the slackness of operations, as many of the mines are curtailing their output or postponing development until the long-promised power is obtainable. The La Rose has a force of 200 men at work at the main mine, where a large stope is being taken off the roof of No. 10 vein from the level 75 ft. below the adit-level. A good ore-shoot has been developed at this depth. On No. 3 the drift at the 135-ft. level has been carried for several hundred feet, the vein showing an average of 3 in. of high-grade ore. A lengthy cross-cut is being driven under the high bluff on the east side of the property. Stoping is being done on the 75-ft. level of the McDonald vein, along a 250-ft. ore-shoot. Development is being actively carried on at the Lawson property where 130 men are at work with fair results. A larger force will be taken on as soon as power can be obtained. The Temiskaming has the deepest workings of any mine in the camp, the main shaft being down 420 ft. At this depth the vein has dipped to the east but at the bottom of the shaft there is a large body of milling ore, distinct from the vein. The company has a year's supply of concentrating ore on the dump and two years' supply above the 300-ft. level, to which winzes are being sunk. The Little Nipissing is taking out high-grade ore from a vein at the 100-ft. level, on which a winze has been started and a raise driven, blocking out ore 36 ft. in depth by 65 ft. in length. The vein is 14 in. wide, and the walls are shot with native silver. The annual statement of the McKinley-Darragh shows gross receipts, including balance from previous year, $639,442, from which were paid for operating expenses and improvements $294,262, and as dividends $224,493, leaving a balance on hand of $120,686. In 1909 the production was 1,297,530 oz. of silver. The ore reserves at the McKinley are estimated at 4,975,000 oz., and at the Savage 755,000.

The total shipments from the Gowganda district since January 1 amount to 124 tons. The Blackburn has furnished 60 tons, and the Reeve-Dobie 62, the Burke-Remey having made a test shipment of two tons. The Morrison property in this area has been turned over to an English syndicate on an option. The syndicate undertakes to spend $100,000 in equipment and development before August, the option price being $1,000,000.

The rush to Porcupine has slackened somewhat, but great activity is being shown in building and in taking in supplies. Development work is furthest advanced on the properties of the Timmons Brothers, who are endeavoring to solve the question as to whether the good ore persists in depth. At the Hollinger, McMahon, and other claims on which they hold options, they have 40 men at work, and two shafts are down about 40 ft. Mining experts attach but little importance to the continued occurrence of free-gold, which often tends to disappear not far below the surface, holding that the real problem to be settled before the worth of the area can be determined is whether it is followed by sulphide ore in depth. This will indicate whether Porcupine has a future as a mining camp. In any event mining will be a costly business, requiring much expensive machinery and the returns will necessarily be slow. It will be no poor man's camp like Cobalt in the early days, when the quick profits from surface ore laid the foundation for large fortunes, and furnished the capital for regular development. The Scottish Ontario Mining Co., the Canadian branch of J. S. MacArthur & Co., of Glasgow, Scotland, who hold six of the Bannerman claims, are preparing to install an up-to-date plant and undertake active development. Buildings are now in course of erection, and the equipment will include a 10-stamp mill, and should results justify it, operations will be undertaken on a very extensive scale. Numerous assays of ore from various portions of the company's properties are said to show an average of $200 per ton.

The Ontario Government is showing a little more activity in protecting the public from imposition by wild-cat promoters than it has done in the past. The small investor lately has turned a deaf ear to gold and silver flotations, and the industry of the promoter has been turned in a new direction. Following the discoveries of Alfred von Hammerstein in Alberta, the wild-catters have been booming Alberta oil companies, with holdings many miles away from any known deposits, the public having but a hazy idea of Western distances. The game, however, was brought to an abrupt conclusion by prosecutions for violating the Companies Act in failing to give the information required in every prospectus or stock advertisement. One of the oleaginous promoters, Henshaw Maddock, of the California-Alberta Oil Co., was fined $200, and A. J. Davis, of the Chicago-Alberta Oil Co., $100, which proved a sufficient deterrent to further proceedings. So far there has been a conspicuous scarcity of Porcupine flotations, good or bad,

GOLDFIELD, NEVADA.

Clermont. — Character of Ore in Depth. — Florence Goldfield. — Diamondfield Black Butte.—Gold Bar and C. O. D. Consolidated.

During the past week a constant improvement has been noted in the assays taken on the 1000-ft. level of the Clermont workings of the Consolidated mines. For several days past average assays from large seams in the face of the drift have yielded 5 oz. gold. The manager, J. R. Finlay, said in an interview that he was unwilling to announce that the real ore-shoot had been penetrated at this depth, but apparently an ore-shoot was being approached, and the indications at the time were most encouraging, with the formation identical in character with that exposed on the 900-ft. level. To reach the vein from the station at a depth of 1000 ft. it was necessary to cross-cut a considerable distance, and the drift had progressed some 60 ft. in vein-matter before the assays indicated the near proximity of paying ore. This ore still shows in seams only, according to the manager, and no large orebody has yet been penetrated on the deepest level. The raise above the 1000-ft. level is still in ore of good quality. The size of the ore-shoot is as yet undetermined, but it is wider than the raise. Assays from this ore have varied from $20 to $90 per ton. The percentage of copper in the ore on and near the 1000-ft. level is no greater than on the 100-ft. There is absolutely no truth in a widely circulated report to the effect that the Consolidated is making a separate dump of copper-bearing ore at the Clermont mine. The manager's report, covering operations in January, shows a larger amount of concentrate than usual in process of treatment at the end of January, and it is estimated that 60 tons of concentrate, containing 1000 oz. gold, were carried over that should be included in the January production. This was owing to the larger tonnage treated, following the installation of additional equipment in the mill.

In the absence of Thomas G. Lockhart, president of the Florence Goldfield Co., who is now operating in the California oilfields, the policy of the Florence company as to future dividend-disbursements cannot be learned. From information obtainable the Florence is making excellent profits, treating 150 tons per day of $25 ore and better, by approved processes, and effecting a high recovery of gold. The manager states that preparations are being made to enlarge the main shaft to the 500-ft. level, and that he has sufficient ore of good quality broken in the Little-Florence stopes to supply the mill while the work in the shaft is in progress. One of the richest ore-shoots in the mine is now being opened on the 500-ft. level near the Engineers' lease-workings, and stopes of large size will be opened from the sill-floors on three levels near the main workings. It is said that ore reserves continue to increase well in advance of the tonnage required to supply the mill.

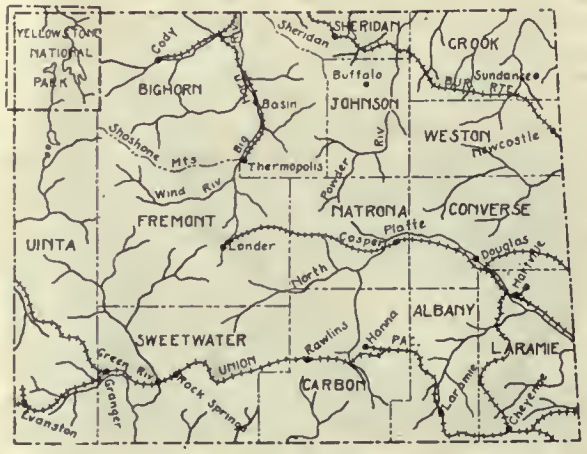
Stimulated by the discovery by lessees of a rich vein on the Diamondfield Black Butte, work has been started on company account. A cross-cut from the original adit is being driven toward the vein, and a change in the formation is already apparent, with seams of talc coming in. This is near the ground from which a large production of shipping ore was made four years ago, and where the high-grade ore in the flat vein apparently pinched out. The lessees on the Black Butte have recently made several shipments of ore, sampling $200 per ton, from the winze sunk at the end of the upper adit. A raise is being driven to the vein from the lower and longer adit, with the indication from surveys that this will require not over 40 ft. of work. Ore is now being shipped from the Gold Bar workings of the C. O. D. Consolidated by lessees who have a five-year lease on this shaft, and who will build a 50-ton mill. Late development in these workings has resulted in opening veins of shipping ore, and two carloads of $60 ore have just gone out. Late reports say that on the 300-ft. level there is a 9-ft. face of $120 ore, but the ore-shoots vary in width, and while there is a large tonnage of excellent milling ore exposed, the high-grade is by no means uniform in any of the veins. Driving is in progress from the 800-ft. station of the Annex shaft on the Polverde, where ore-bins have been installed, and shipping will begin at once. The shaft will be continued to the 1000-ft. level. The Grizzly Bear shaft is nearing the 1000-ft. point, and will sink to the Mohawk vein.

DENVER, COLORADO.

Coal Land Cases. — San Juan Conditions. —Petroleum.

The extent of the coal land fraud cases is realized by few people. In Colorado, alone, 20,000 acres of coal and forest lands are in litigation. The greater part is in Routt and adjoining counties. The famous Kietel case, involving 2400 acres, and the case against the Union Land Co., controlling 5600 acres, are now being argued. In Wyoming, the Government has secured a temporary injunction against the Owl Creek Coal Co., preventing it from operating its Gebo mine during the arguing of the case. This mine employs nearly 1000 men. The case is to decide the title to 9500 acres of the best coal land in the State, lying just north of Lander. The investigation has been going on for three years.

The San Juan district has been shut off from the outside world for several days at a time during the past month by the heavy snowstorms and slides so common at this time of the year in that district. The Yukon group of claims on Boulder mountain, near Silverton, has been steadily developed since its purchase by the W. B. Lowe Mining & Milling Co. last November. The management has recently increased the working force and expects to be able to make a heavy



Map of Wyoming.

shipment as soon as the season opens. The pyritic smelter north of Ouray has been sold to Easterners who intend to operate it during the coming summer. The first payment has been made and ore contracts are being negotiated with nearby producers. With the smelter in operation many properties now idle will resume operation. A contract has been let to rebuild the Midway terminal of the Silver Lake tram in Arastra gulch. The material is being assembled and the work will proceed despite the weather. It is understood that the company will shortly take over the leases and operate the Silver Lake mine on company account. The U. S. R. & R. Co. has re-classified their wage schedule which results in an increase to 70% of their employees at Colorado City.

The report of the State oil inspector indicates that production from the Florence and Boulder fields was slightly less for the past year than for 1908. Of the new localities showing oil the most promising are those in Routt and Rio Blanco counties. A producing well has been brought in near Cody, Wyoming, by C. L. Sheedy, operating under lease from the Western Oil & Gas Co. The Fidelity Oil & Gas Co., operating in the Boulder field, has struck oil at a depth of 2750 ft. on the Moffat place, about a mile north of any producing wells in the district. After two years of litigation the United Oil Co., of Florence, has won its suit against the Inland Oil Co., of Boulder. It was shown that the former secretary-treasurer of the United had used funds and equipment of that company to develop the properties of the Inland of which he was the principal stockholder. The decree gives the United three-fourths of the stock of the Inland, and a cash judgment of $14,671, to pay for the use of its property.

MEXICO.

Greene-Cananea.—Llanos de Oro. — Dolores, Chihuahua. — Conchos Dam and Railroad.— Tula Iron Works. — Pachuca Enterprises.—Oil Situation.

The Greene-Cananea Copper Co. has started the present year with a smaller production than at the beginning of 1908. The January output was 3,500,000 lb. copper, 464 oz. gold, and 85,132 oz. silver, as against 3,848,000 lb. copper, 558 oz. gold, and 89,495 oz. silver in January of the preceding year. The work of reconstructing, and installing new equipment, which has claimed the attention of the company since the Cole-Ryan interests secured control, has been practically completed, and the Greene-Cananea is now in a position to greatly increase its output.

The affairs of the Llanos de Oro Consolidated Mining Co., operating in the Altar district of Sonora, have been taken into court at Hermosillo, and Louis H. Mooser, of San Francisco, has been appointed receiver. The original company was organized to work extensive deposits of auriferous gravel, and when they failed to develop according to expectations, adjacent gold veins were acquired and a reorganization effected. The company placed a 50-stamp mill in commission last year. Epes Randolph, of Tucson, Arizona, has been prominently identified with the enterprise. The Lucky Tiger Gold Mining Co., owning the rich El Tigre mine, has commenced work on a cyanide annex that will materially increase its production. The mine is developing in a most satisfactory manner, and ore to the value of millions of dollars is now blocked. Much excitement is reported from the vicinity of Nacori, 100 miles south of Nacozari, as the result of the discovery of a rich and wide gold-silver vein, which can be traced, it is said, for several miles. Many denouncements are being made. Mrs. Myra T. Seymour, owner of the Torres & Prietas railway, who has been in England for some time, is said to have arranged with British interests for the extension of the line east through the Barranca region to a connection with the Yaqui river extension of the Southern Pacific.

The annual report of the Dolores Mines Co., operating in western Chihuahua, shows a total income for 1909 of $1,160,531, and net profits of $462,896. Dividends to the amount of $238,800 were paid, and a surplus exists of $740,646. The 1909 earnings were nearly $400,000 greater than those of 1908, and the net earnings increased $120,000. The ore reserves at the end of the year were estimated to have a value of $1,702,620. Bernard MacDonald, the Guanajuato cyanide expert, has taken the management of the Veta Colorado Mining & Smelting Co., at Minas Nuevas, in the Parral district of Chihuahua, and will push the completion of the 500-ton cyanide plant, which was started several years ago. Contracts for the additional equipment necessary have been made. It is planned to immediately resume development in the Quebradillas and other mines of the company. The Veta Colorado has been at a standstill since 1907, as a result of the financial depression in the United States. The English firm of S. Pearson & Son, Ltd., has finished grading for the railroad that will handle materials from Santa Rosalía, on the National Railways, to the site of the great dam and power-plant on the Conchos river, to be built at a cost of ₱15,000,000 by the Mexican Northern Power Co., a Canadian concern. As soon as track can be built work on the dam will start, and 3000 men will be given employment. Power from the Conchos river plant will be transmitted to the Naica, Parral, Santa Eulalia, and other mining districts of Chihuahua.

Alfred Rodriguez, a Mexican congressman, who for several months has been working on a project for the erection of a zinc smelter in Torreón, states that the plant is practically assured. French capitalists are now negotiating for productive zinc properties owned by José Lago at Plomosas, on the Orient railway in Chihuahua.

The Tula iron mines, in the Tapalpa district of Jalisco, which have been worked for more than a century, and which are known throughout Mexico for the superior quality of their product, have passed into the control of the Mexico Iron & Steel Co., of Boston, through a fourth payment of ₱100,000 on the purchase price of ₱1,000,000. A deal for the properties was made by Boston people last July, and the company formed with a capital of $5,000,000. It is announced that French capitalists will join with the Boston men in the exploitation of the iron deposits, and the timber and lands that go with them. An investment of $500,000 in smelting furnaces, a steel plant, tool and implement factory, and tramways is planned. The Lupita Mines Co., of Colorado Springs, owning the Lupita mines in the Mascota district of Jalisco, is resuming milling after three years of idleness. A cyanide plant has been added to the reduction works. In an extension of the Lupita mines, recently opened by the company, ore running as high as 14 kilograms silver per ton has been opened.

After securing data on the probable tonnage from mines in the Magdalena district of Oaxaca, the management of the National Railways has decided to build 17 miles of railroad to reach that district. The railroad is expected to result in the blowing in of the 50-ton Magdalena smelter, which has been idle for a long period. A number of Oaxaca mining enterprises were crippled by the failure of the United States Banking Co., of Mexico City, which maintained a branch in Oaxaca. The failure caused the suspension of work on the 100-ton reduction plant at the San Francisco mine, in the Taviche district, and it may be some time before the plant can be completed. The property is held by the Tehuantepec Silver Mines Co. Good progress is being made in the erection of the Victoria-Tapada reduction plant in the Totolapam district of Oaxaca. The plant will handle custom ores, and is expected to be of much benefit to mining interests in that region.

Santa Gertrudis Patio.

The Pachuca district of the State of Hidalgo, now in the limelight by reason of the Santa Gertrúdis purchase, promises to secure additional British capital through the transfer of the Dos Carlos properties, adjoining the Santa Gertrúdis mines. M. W. Greit, representing the British-Mexican Exploration Syndicate, of London, has taken an option to purchase Dos Carlos No. 2 and No. 3 for ₱1,000,000, and H. S. Walker, a mining engineer who examined the properties, has left Mexico for England to render his report. The option calls for a substantial payment within 60 days, and the remainder within a period of three years. The Dos Carlos properties, comprising 114 pertenencias, are owned by Pachuca men, and the western portion, known as Dos Carlos No. 1, and having an area of 42 pertenencias, was leased some time ago to the Phoebe Mining & Milling Co., which concern is sinking a shaft. It is the opinion of engineers who have made investigations that the Santa Gertrúdis veins will be found also in the Dos Carlos properties in depth, and if the deal is closed the sinking of a deep shaft will be commenced at once. The British interests represented by Captain Greit have holdings in Sonora, and recently options on several properties in that State were arranged. Hugh Rose, manager of Santa Gertrúdis, announces that the 300-ton cyanide plant, practically completed by the old Santa Gertrúdis company, will be given the finishing touches and soon placed in commission. The Camp Bird representatives are not impressed with the io-

cation of the new plant, and it was thought that it might not be operated. Plans for another and larger plant, to be built near the San Francisco shaft, are being prepared. It is now announced that the Mexican Light & Power Co., the big Canadian concern, has purchased all the stock of the Hidalgo Electric & Irrigation Co., and is consequently in complete control of the power situation in the Pachuca district. A working agreement was at first announced. The mining concerns of the Pachuca district are now using several thousand horse-power, and much additional power is demanded. Power from Necaxa will reach Pachuca in June.

A pipe-line and narrow-gauge railway, giving the Furbero oilfields of the Oil Fields of Mexico Co., in the State of Vera Cruz, connection with the Gulf port of Tuxpám, are nearing completion, and it is expected to start pumping oil early in March. The pipe-line and railway have been built at a cost of ₱2,500,000 by S. Pearson & Son, Ltd., which firm has a contract with the Oil Fields of Mexico Co. for a maximum of 6000 bbl. of oil daily for a period of 12 years. The Pearson interests and their Mexican ally, the Compañia Mexicana de Petroleo El Aguila, are anxious to place the Furbero pipe-line in commission, as for months they have been compelled to import Texas crude oil for their refinery at Minatitlán. Their war with the Waters Pierce Oil Co., the Standard concern, for the control of the Mexican field has created a demand at the refinery that their wells are at present unable to supply. Officers of the Oil Fields of Mexico Co. estimate the production of the Furbero wells at 20,000 bbl. daily, and the pipe-line has a daily capacity of 12,000. The Pearsons may arrange to take up to the full capacity of the pipe-line. The East Coast Oil Co., a Southern Pacific concern, has contracted to purchase 60,000 acres of oil land in the Topila district of Vera Cruz for ₱1,250,000. The company is now sinking a well on the land, and will put down others. In that district, a short time ago, a well was brought in by the Mexican Fuel Co., a Waters Pierce concern. The Southern Pacific interests are anxious to develop fuel-oil supplies for their Mexico lines, and contemplate extensive oil exploration work along the west coast of Mexico. They recently abandoned a well in the Tuxpám district of Vera Cruz, after reaching a depth of 4000 ft. without a satisfactory showing.

BUTTE, MONTANA.

February Copper Output.—Decision in Magone Case.—East Butte and Davis-Daly.—The Merger with the Anaconda.—Hypocka Mine.—John Gillie to Retire.—Piltsmont Smelter.

The copper production by the Butte companies in February was the lowest monthly output in years, caused by the strike of engineers and the shorter month, together with the policy of curtailment that had been observed before the strike began. According to estimates the total production amounted to 14,000,000 lb., the different companies contributing as follows:

Companies.	Copper, lb.
Boston & Montana	4,200,000
Anaconda	3,100,000
Butte Coalition	2,100,000
North Butte	1,225,000
Original	720,000
East Butte	534,000
Butte & Boston	435,000
Trenton	333,000
Washoe	230,000
Parrot	150,000
Miscellaneous	973,000
Total	14,000,000

Mining men from the Atlantic to the Pacific will be interested in the decision just handed down by Federal Judge William H. Hunt in favor of the defendant smelting companies in the celebrated Hugh Magone case. This was first brought to public attention a few years ago when Mr. Magone applied for an injunction to restrain milling and smelting companies operating in this city and Anaconda from polluting the Deer Lodge river, and demanding damages for injury claimed to have been done to his land in the Deer Lodge valley. Judge Hunt referred the matter to the master-in-chancery to hear evidence, and taking of testimony consumed a large amount of time. The litigation has became nearly as famous as the smoke-case. From the findings of the master-in-chancery, Judge Hunt refused to issue the injunction, but Mr. Magone is given judgment for $572.50. He demanded damages on account of tailing and other waste distributed over his farm through irrigation ditches. Judge Hunt held that Magone was not entitled to any such damages but may collect for injury done by the overflow of the river upon his land. The court held that the chief damage resulted from the use of polluted water in the irrigation ditches, and that there was no foundation for the complaint. Judge Hunt then further pointed out in his decision that the prior appropriator has the right as against a subsequent appropriator to use the water for mining and smelting as well as for irrigation purposes. He says that in the enjoyment of this right there is also necessarily included the right of pollution of the water to some extent, provided the use makes pollution necessary. It may be very light perhaps, if the use is for irrigation, but oftentimes comparatively serious if the use be for mining or smelting. The judge points out that

Anaconda Mill.

defendants' appropriations were several years earlier than the appropriation made by complainant. He says that complainant knew of the earlier right and their uses, and the pollution of the stream has been no greater than necessarily and unavoidably connected with the successful operation of the defendants' smelters. The Anaconda Copper Co. was included in the suit, but the judge held that it had done no substantial damage and dismissed it from the action. The percentages of payment fixed by the court against the companies involved were: Colorado Smelting & Mining Co., 24%; the Colusa-Parrot Mining & Smelting Co., 16; Parrot Silver & Copper Co., 18⅔; Montana Ore Purchasing Co., 24; and the Butte & Boston Consolidated Mining Co., 17½. The court gave the defendants 60 days in which to make the payment, and if at the end of that time payment is not made, an injunction will issue.

A story is circulating in the East to the effect that a movement is on foot for a consolidation of the East Butte and Davis-Daly interests, it being stated that a brokerage firm of Boston is willing to pay the proposed assessment of Davis-Daly on condition that it be given control of the Heinze company and the expenditure of the money received from the assessment. However, the whole story is denied. The Davis-Daly company is capitalized for 670,000 shares, of which 70,000 shares are in the treasury, so that the Davis-Daly people take the view that the Boston brokerage firm which controls East Butte would willingly pay, say, a $3 assessment, in order to get control of the property. There seems to be a well founded report that an effort to

raise $150,000 has failed, and now Mr. Heinze proposes to sell the 70,000 shares of treasury stock to replenish the treasury, and thus escape levying an assessment. As soon as the proposed tramway is built from the Colorado mine to connect with the railway, the shipment of Davis-Daly ore to the Basin concentrator will be commenced, and the company will begin to earn money.

Another story is out concerning Tuolumne. It has been stated that North Butte is not to be taken into the merger, but that Tuolumne will. Both the North Butte and Tuolumne people deny the story, and among people supposed to be well posted in what is transpiring in mining circles there is a belief that there is nothing to it.

B. B. Thayer, president of the Anaconda Copper Mining Co., and C. F. Kelley, chief counsel of the Amalgamated Copper Co., have arrived in this city from New York to make preparations for the meeting of the Anaconda company on March 23 for the purpose of increasing the stock of the company and completing the plans for the merger of the Butte mines. There is not the least shadow of doubt that the plans as agreed on will go through without serious opposition. In this connection it may be mentioned that a special meeting of the Boston & Montana company is called for March 26, three days after the Anaconda meeting, for the purpose, as set out in the notice, to consider a proposition to sell and dispose of the whole of the property and assets of every kind to the Anaconda company for a part of the capital stock of the Anaconda company. The meeting will take place in this city at 10 o'clock in the morning.

The East Gem mine case has been decided in favor of Maurice Eisenburg and against the H. L. Frank estate, the court finding that Eisenburg is entitled to an eighth interest in the property. Eisenburg and the late H. L. Frank had a lease on the property. Later Frank bought the property and sold it to the North Butte. It was Frank's contention that Eisenburg's interest ceased with the lease, and that he bought the property on his own account and with his own money.

The Tuolumne Copper Mining Co. has filed its annual statement as required by law. The capital stock of the company is $8,000,000, fully paid up, while the assets consist of mining claims to the value of $400,000, cash $142,444, machinery, etc., $43,918, miscellaneous items $4500, making a total of $590,862. There are no liabilities.

An order of court has been made appointing a receiver for Heinze's Hypocka Mining Co. The appointment was made in order to collect an unsatisfied judgment of $12,500 secured against the company by an employee who was injured while at work in the Minnie Healy mine under the Heinze ownership. The Hypocka was organized by Heinze several years ago to meet some of his purposes during his mining litigation, and the company was supposed to own the shaft and cages of the Minnie Healy. The company was capitalized with 4000 shares of stock of a par value of $25 per share. Only a few shares were issued, as Heinze retained 3925 shares. Under the laws of Montana the stockholders are liable for the full par value of the stock, and it is proposed to ask Heinze to pay for the shares he owned in the company.

There is also an unsatisfied judgment against the Pittsburg & Montana Copper Mining Co., and a receiver is asked to collect the amount, but action has been deferred pending word from the stockholders. The Pittsburg & Montana company is practically out of existence, as its properties were sold to satisfy mortgage-bonds held by the Pittsmont company, and the latter in turn transferred the property to the East Butte Mining Co. The recent labor troubles have renewed the rumors concerning the retirement of John Gillie as general superintendent of the Amalgamated properties, it being stated that Mr. Gillie rather inclined to the side of the engineers who walked out, which was not in accordance with the desire of John D. Ryan, president of the Amalgamated Copper Co. Rumor declares the retirement of Mr. Gillie will take place on April 1, the date when the merger of the Butte mines goes into effect. Mr. Gillie has been connected with the mines here for many years, and should the rumor prove true there will be a feeling of regret among all classes of citizens.

Official reports show that the East Butte Copper Mining Co. and the Pittsmont smelter are turning out copper at the rate of about 7,000,000 lb. per annum. It is stated that whenever the market justifies it the company will double the production. In October, November, December, and January the total output was 2,315,776 lb., which is at the rate of 6,947,228 lb. per year. The East Butte mine and the Pittsmont smelter were not interfered with during the engineer trouble.

RAY, ARIZONA.

Ray Consolidated Ore and Mill.— Arizona-Hercules.

At Ray are the properties of the Ray Consolidated Copper Co., situated mainly on the west side of Mineral creek, six miles north from Kelvin, a station on the Arizona Eastern, situated on the Gila river. To facilitate mining and milling operations the Ray company has built a standard-gauge railroad from Kelvin to the mines at Ray. Its mill-site is two miles east of Winkelman, a station 12 miles up the Gila from Kelvin, where an ample water supply and sufficient tailing area have been obtained. The orebody is in altered Pinal schist, is flat in position, has a strike northwest approximately 6000 ft., and is of undetermined width. This mineralized area has a schistose capping impregnated with oxidized iron, 200 to 250 ft. in depth, below which is the main body of chalcocite, said to average 2¼% copper. While the copper glance is generally disseminated through the gangue, there are many streaks and bands of this ore in concentrated form. The development work shows some narrow dikes of granite-porphyry and diabase which are also mineralized. A main haulage level starts some 20 ft. higher than the bed of Mineral creek, going 2000 ft. horizontally into the orebody to a place near the southern boundary of the mineralized zone. This level is 8 by 14 ft. and double-tracked. On both sides the ore is blocked out to a considerable extent. This level connects with a 300-ft. 2-compartment shaft which sinks close to the northern limit of the orebody, from the three stations in which levels have been driven in ore. An ore-loading pocket of 600 tons capacity is being put in at each station to receive the ore from these levels. Ore is to be drawn from the pockets through air-actuated gates into 12½-ton skips in the shaft. The haulage system will consist of 5-ton cars in train, drawn by 10-ton electric locomotives. Three cars at a time are to be dumped by a revolving tipple at each ore pocket. The hoisting will be done by electrical equipment of the company's design. A 30° incline, 7 by 16 ft., 3-compartment, has been driven down on the edge of the orebody, connecting with the various levels, which is to be used exclusively as a passageway for men and the haulage of supplies. Besides the development work in progress on the principal levels, as above outlined, there are 12 churn-drills kept busy doing exploratory work on other parts of the group. The coarse-crushing plant will be at the mine, the crushed ore from which is to pass into the bins, thence loaded into railroad cars and transported to the mill. The storage bins at the mill are to hold 28,000 tons of crushed ore. The milling plant, in course of construction, is to have the capacity to concentrate 5000 tons of ore every 24 hours. The crushing department will consist of 16 sets of 42-in. rolls, having 10-in. faces; 24 Garfield Chilean mills, 6-ft. size; both rolls and Chilean mills are of this company's design. The sizing will be done on 48 impact screens, the concentrating by Garfield roughing tables, 72 Wilfley tables, and a type of horizontal-motion suspended vanner. The power plant will contain water-tube boilers, triple-expansion engines, direct-connected to electric generators, equal in the aggregate to 10,000 hp., from which power is to be distributed to the mill and mine. The mill, power plant, and other similar work has been designed by George O. Bradley, the company's mechanical engineer. E. M. Stewart is in charge of the mine work, Ernest Stenger being general superintendent.

The 240-acre group of the Arizona Hercules adjoins the Ray Consolidated and Ray Central on the east, lying mostly on the opposite side of Mineral creek, covering the Ray fault, and extending some distance east of it. The Arizona Hercules holdings extend 3900 ft. along this fault, which is virtually a lode on the contact of diabase and schist with

porphyry. Work on this group is under direction of W. P. Dunham, one of the principal stockholders, who has kept two Star drills in operation for several months, having completed 17 holes in exploration work. Of these holes, 14 are 200 ft. apart, the others being 'scout' holes, 1200 ft. from the regular lines of development. The No. 13 hole, on the east side of the fault, is at a depth of 850 ft., and is said to have passed through three strata of ore, the last one being a body of chalcocite, at 850-ft. depth, in diabase. This is taken as good evidence that the copper ores of the Ray district are not confined to the schist, but that they extend to the formation lying east of the Ray fault, which strikes nearly north.

WASHINGTON, D. C.

Alaska Coal Lands.—Mr. Birch and Mr. Steele Testify.—Copper Properties of the Alaska Syndicate.

The biggest surprise of the year in Washington came when representatives of the so-called Morgan-Guggenheim syndicate appeared before the Senate Committee on Territories and asked for an opportunity to tell about its mineral holdings in Alaska, how they were acquired, how business was being done, and what was wanted for the future. In these days when the heads of great corporations are objecting strenuously to publicity, to Federal incorporation, and to the interference proposed in the administration's legislative progress, this made people sit up. The agents of the syndicate who took this stand were John N. Steele, counsel of the Morgan-Guggenheim people, a brother of Charles Steele of J. P. Morgan & Co., and Stephen Birch, managing director of the syndicate. They announced that they came voluntarily, following a request by J. P. Morgan & Co. for permission to appear to "answer exaggerated reports printed in the magazines and newspapers of the work of the syndicate, formed by that company and the Messrs. Guggenheim". A statement was presented in which it was admitted that an option on the Cunningham coal lands in Alaska was held. It was denied that the syndicate owned any coal lands in Alaska, the following language being used: "The syndicate has not and has never had any interest in any coal lands in Alaska except the interest it obtained under an option given by what are known as the Cunningham claimants in the latter part of 1907. At the time this option was given, Mr. Cunningham and his associates had paid the Government for their claims, and had received from the Government final receiver's certificates". This statement called out a fusillade of questions from Albert J. Beveridge, Senator from Indiana, and chairman of the committee. The representatives of the syndicate admitted that Messrs. Guggenheim had agreed to form a $5,000,000 corporation to develop the coal lands, one-half interest to be held by the Guggenheims and the other half by Mr. Cunningham and his associates. The Guggenheims were to pay $250,000 for their share, and, in addition to that sum, agreed to loan $100,000 if it were needed. Admission was also made that the syndicate paid Cunningham $1359.60 for traveling and other expenses in connection with the examination of the coal properties. Then followed an argument bearing on the right of the Cunninghams to sell their claims. Continuing, the syndicate's statement says: "An examination of their coal properties and of the Bering river field generally was made for the syndicate by a coal expert, who reported very large and extensive tracts of coal lands containing coal of a high grade. In the latter part of December, 1907, the option given by the agreement of July of the same year was exercised." At this point James B. Frazier, Senator from Tennessee and a member of the committee, took up the questioning of Mr. Birch. He drew from him that the coal fields of which the Cunningham 5000 acres are a part contained minable coal to the extent of 500,000,000 tons. As a practical engineer, Birch estimated that this tonnage in the ground was worth $900,000,000. He said that it would take $700,000,000 to mine this coal, leaving a net profit of $200,000,000. He also admitted, under questioning, that the value of the Cunningham coal claims, upon which the syndicate had an option, was $25,000,000. He meant by that, he said, the net profits. At the suggestion of members of the committee, the syndicate representatives produced a copy of the agreement between a committee of the entrymen on the Cunningham coal lands and a representative of the Alaska syndicate. In answer to questions Mr. Birch stated that the syndicate would not get the coal property unless, or until, the claims were patented by the Interior Department.

"What have you done toward securing patents?" Mr. Beveridge asked.

"Nothing," Mr. Birch replied. "It was not in our province to do anything."

"What have you done in the way of developing the coal lands?"

"We have never done anything. The property was never in our hands for us to do anything," said Mr. Birch.

"If the claims were patented tomorrow, would your option still be good?" asked Mr. Beveridge.

"That is what we hope and believe," said Mr. Steele.

"The coal in the Cunningham claims, on which you have an option, you estimate to be worth about $25,000,000?" Mr. Frazier asked Mr. Birch.

"Yes, sir," replied Mr. Birch.

"And your syndicate was to pay $250,000 for an equal interest in them?"

"That was one of the stipulations; yes, sir," was the reply. He explained that the syndicate was to furnish transportation for the coal to seaboard.

"You were greatly interested in seeing these Cunningham people get their patents?" persisted Mr. Frazier.

"Naturally."

"And you say you have taken no interest or steps in getting the claims patented?"

"We have taken an interest but have taken no steps," answered the witness.

The details of the copper mining properties belonging to the syndicate were also the subject of many questions. The syndicate, it was testified, bought out the Alaska Copper & Coal Co. After buying these holdings, some more copper lands were found nearby. These were secured by the syndicate's copper mining company from the Government.

"The company used members to make claims and furnished the money," said one of the witnesses. "After patents had been issued the company got the properties."

"The entrymen were dummies, then?" asked Mr. Frazier.

"No, sir," answered Mr. Birch. Mr. Birch further said that he was one of the locators on the tracts and that others interested in the company were also locators.

"How much land did you locate?" Mr. Birch was asked.

"I couldn't tell you that now," he replied.

"More than one tract?"

"I think so."

"And when you perfected title you turned the property over to the company?"

"Yes, sir, I acted as their agent."

"Did others interested in the company do the same?"

"Yes, sir."

"After we secured control of the property of the Alaska Copper & Coal Co." said Mr. Birch, continuing, "I found some lands nearby that were not located. I took them up for protection, using my own name and the names of others interested in the company."

The lands secured in this way, Mr. Birch said, are only a small portion of the 3200 acres of copper mining land which the syndicate has.

During the course of the hearing Mr. Birch pointed out that the copper and coal properties are worth little without transportation facilities. Railroads are necessary to get the machinery to work the mines to them and to haul the ore to the seaboard. It was brought out that the Alaska syndicate controls the railroad affording transportation to and from the district in which its copper mines are located.

"Controlling the transportation by which to get the machinery in and the ore out, wouldn't it seem that the Alaska syndicate has a tremendous advantage in the purchase of mines it does not own?" asked Mr. Beveridge.

"The Government will prevent that," Mr. Birch replied.

"How?"

"By governing the rates."

General Mining News.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—The Copper Queen company has decided to withdraw from the Courtland district after having kept a force there on development work for a year, during which time a considerable amount of work has been done at the Casey, Brown, and Silverton shafts, under direction of P. G. Beckett. It is considered now that results obtained do not justify further development. The steam-electric power-plant built jointly by the Copper Queen company and the Great Western Copper Co., will be operated by the latter for air-compressors and hoists. The Great Western Copper Co., operating two shafts at Courtland, is shipping 100 tons of ore per day to the El Paso smelting plant. This ore consists of azurite, malachite, and chrysocolla, with a small amount of cuprite. A pitch-like ore which occurs in considerable quantity, is locally called black chrysocolla. Thus far, the shipments are made from the company's Mary shaft, in the north end of the district, mostly from stopes between the 100 and 200-ft. levels. Work is in progress on the Mamie group, in the south part of the district, where there is a 300-ft. shaft, sunk within the last year. A cross-cut will be driven from this to the old workings that were made 12 to 15 years ago, known as the Humboldt. An adit drainage level has also been driven to the old workings. W. G. McBride is now superintendent of the property and has 85 men employed.——The Calumet & Arizona company has done a great deal of work in Courtland camp in the last year, and has shipped some ore as the result of development. Its Germania shaft, 500 ft. deep, is on the same lode as that on which the Great Western sank its Mary shaft. Its April Fool shaft, 900 ft. north of the Germania, has reached a depth of 500 ft., and the two shafts are connected on the 500-ft. level. It is understood that the results of the year's work are not especially satisfactory.——The Gold Queen Mining & Milling Co., in which local people are concerned, has done considerable work on a quartz vein, in a granite-porphyry hill two miles north of Courtland, where free-milling gold ore has been found, assaying $6 to $8 per ton. A 200-ft. shaft has been sunk with the aid of a whim, and now a gasoline hoist is to be put in.——The Copper Belle mine at Gleeson, controlled by N. L. Amster, is being operated by the Shannon Copper Co. as lessee. As Mr. Amster is president of the Shanuon Copper Co. and Arizona Commercial Co., the three concerns are closely allied. The Copper Belle has an irregular orebody in limestone, along a contact with porphyry. It is opened by a 300-ft. vertical shaft, having working levels from the 100, 200, and 300-ft. stations. The ore contains about 1% copper, 45% iron, 40% sulphur, 10% silica, the balance lime, with $1.25 per ton in gold and silver. It is valuable chiefly as a fluxing ore to mix with the silicious copper ores of Globe and Clifton. Shipments consist of 50 tons per day to the smelting plant of the Arizona Commercial Co., at Globe, and 125 tons per day to the Shannon plant at Clifton. There is a working force at the mine of 125 men, with H. H. Dyer as superintendent.——The Tejon Mining Co., with W. H. McKittrick as principal stockholder, is developing a north and south lode that parallels the Copper Belle ore-zone. Its hanging wall is the limestone cap-rock of the mountain, the foot-wall being porphyry. The vein, which has a dip east of 35°, is opened by a cross-cut of 174 ft. from the side of the mountain, then by an incline on the foot-wall. The ore assays 85% silica, and $6 per ton in gold and silver. About six cars per week is to be shipped to the smelting plants at Douglas to be used as converter lining. This vein is identical with the old Tom Scott and Silver Bill veins, worked profitably 30 years ago. The Tejon, of which L. I. Thiers is superintendent, has another vein wholly in the porphyry, containing sulphide ore.

Courtland, February 26.

GILA COUNTY.

(Special Correspondence).—The north and south cross-cuts on the 650-ft. level of the Superior & Globe property, near Globe, has been driven 230 and 245 ft., respectively.——The Live Oak Development Co. is installing a 10-drill compressor, which is expected to be in operation within a week.——The Superior & Boston Copper Co. is installing a 1000-gal. Prescott pump at the sixth level of the McGaw shaft. Sinking is being continued in the shaft below this level to the eighth, where the Great Eastern vein will be explored.——An 8-ft. stratum of slate and shale has been passed through in sinking the Williams shaft of the National Mining Exploration Co., which is now 580 ft. deep.——The second churn-drill hole on the Cordova Copper Co.'s property has cut considerable sulphide from the depth of 60 ft. to the present depth of 250 ft. This hole is 500 ft. east of hole No. 1, where 300 ft. of sulphide was drilled through.——On the property of the Miami Copper Co., the No. 4 drill-hole is in sulphide ore at a depth of 350 ft., and the fifth drill-hole is being started.

Globe, February 26.

CALIFORNIA.

AMADOR COUNTY.

The drift at the Fremont-Gover mine, near Drytown, opened a pocket and approximately $50,000 worth of high-grade ore was taken out.——The Bunker Hill company paid its regular dividend of 5c. per share February 15.——The South Eureka, at Sutter Creek, has finished the installation of 20 stamps in the mill and now has 60 stamps dropping on ore from the South Eureka mine, 40 in the South Eureka, and 20 in the Central Eureka mill. It is the intention of the company to add another 20 stamps to its mill.——The Mason mine has been sold to local operators. There is about 160 acres in the group and a mill has been erected on the property.

INYO COUNTY.

The Four Metals company, operating in the Keeler district, is stoping on the 1100-ft. level of the old Union mine which is 200 ft. below the old workings. The vein is from 2½ to 3 ft. wide, and the ore is shipped without sorting to the plant of the United States Smelting Co., at Salt Lake.——The turbine for the power-plant at the Buckeye mine, south of Fish Springs, has been installed and it is thought that the mill will be ready for operation within the next two months.——About 12 carloads of ore per month is being shipped from the New Coso property. The ore is being stoped on the 400-ft. level where the richest portion of the vein is about 4 ft. wide and nets the company approximately $50 per ton.

LOS ANGELES COUNTY.

The Sierra Madre club, of Los Angeles, has guaranteed $10,000 to defray the expenses of holding the meeting of the American Mining Congress in that city September 26 to October 1 and will endeavor to increase the fund to $25,000.

NEVADA COUNTY.

(Special Correspondence).—Operations have been temporarily suspended at the Diana mine, in the Grass Valley district.——The Jenny Lind mill will commence a trial run on 200 tons of gravel this week. It is reported that the main channel has been intersected.——The Fairview is arranging for the completion of its mill and tramway.——The Giant King, in the Washington district, is sinking an air shaft.——In the North Star mill 80 stamps are dropping steadily and about $100,000 per month is being produced. Considerable development is under way below the 4000-ft. level.——The Curnow group of seven quartz claims at Columbia have been bonded by the Roseville Mining & Milling Co. The adit is in 170 ft. and is expected to cut the main vein in about 100 ft.——The shaft at the Prudential is going down steadily. It is planned to drive a cross-cut from the shaft to open the vein at a point 200 ft. below the present workings. The mill is operating 10 hours per day.——The 10-stamp mill at the Pittsburg has resumed on ore from the drift on the 1000-ft. level. The vein at this point is but a few inches wide, but assays well. A station is being cut at the 1100-ft. level from which a cross-cut will be driven to the vein. Mark B. Kerr is manager.——The erection of the head-frame at the Mountaineer shaft will be

under way before the end of the week; 60,000 ft. of Oregon pine has just been received for the work.

Grass Valley, February 28.

SIERRA COUNTY.

The lawsuit which has stopped the work at the Sixteen-to-One mine, at Alleghany, has been settled and operations have been resumed at the property. H. L. Johnson, owner of the Tightner mine in the same district, is now manager for the new company which has been organized to work the property.——The new hoist at the Sierra Buttes has been finished and work is to be started putting in several thousand feet of new pipe to the mill.——A rich shoot of ore has been opened in the Rainbow mine near Alleghany. The discovery was made east of the portion of the mine in which the former rich ore has been opened.——On the Phippen-Davis property, at Mountain House, a drift is being driven on a 3-ft. vein rich in arsenical sulphide.——The drift at the Swastika mine, at Sierra City, opened a new shoot and some rich ore is being taken out. Lawrence H. Holley is superintendent.

TUOLUMNE COUNTY.

(Special Correspondence).—The Republican mine, near Jacksonville, will be operated by a company composed entirely of local people, among whom are T. F. McGovern, of Sonora, who for many years has been in charge of the property, and G. W. Price. The work of unwatering the mine has been started.——G. K. Allen has secured a bond on a promising claim above the Riverside mine and owned by Fred Hibbing. A 3-ft. vein with considerable rich sulphide has been opened.——As a result of the recent rich discovery, the company working the Gold Spring mine will probably equip the property with a larger surface plant than at first decided upon.——William Heath and associates, who are working a claim in the Buchanan district, report they have an 8-in. vein from which they are obtaining $35 per ton with an arrastre.——The Tailahoosa Mining Co., whose property is situated east of Groveland, will soon commence development work on a large scale. The company is soon to make the final payment on the property.——Machine-drills are now used in the Mangante mine, near Jamestown, the work of installing the compressor having been completed several days ago.——The hoist at the Shawmut mine is again in operation, but the milling of ore will not be resumed for a few weeks more.——The mill at the Dutch mine has been thoroughly repaired and will be started soon on ore which is being extracted from three levels.——The re-trial of the case of Daniel Manning *v.* App Consolidated Gold Mining Co., in the Tuolumne County Superior Court, ended February 19, the verdict of the jury awarding plaintiff damages in the sum of $17,500. Manning was injured in the App mine, at Quartz, in 1901, by a timber, which fell from the skip to the bottom of the shaft, where he was working. The first trial, which was in 1902, resulted in awarding the plaintiff $5000.

Tuolumne, February 28.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A bonanza discovery was made last week at the Saxon mine, in the Georgetown district. In driving the adit the vein was intersected 55 ft. from the portal, containing a streak of ore that is from 6 to 10 in. wide and assays from $125 to $150 per ton gold and silver. A. Robert is operating under bond and lease.——Another vein has just been cut by the LaMoe adit, on Breckenridge mountain, a body of ore having been cut that is from 8 to 12 in. wide.——Work has been resumed on the Pinion & Annex property on Alpine mountain.——The Two American Sisters Mining, Milling, Power & Electric Co. is preparing to resume work in the Princess of India adit, the portal of which is situated on Columbian mountain. It is to be driven 1200 ft. farther to intersect the American Sisters vein. J. J. White is manager.——The Central adit of the Big Five company, operating in the Idaho Springs district, was driven 95 ft. during the month of January, making the total distance 8067 ft. The next property of promise to be reached is the Lake, which has been a heavy producer from the shaft workings.——A body of ore 8 ft. wide has been opened in the New Era property at Freeland and the entire width is being stoped, the product being sent to the Modern smelter. J. Couzins is the lessee.——A 6-in. streak of smelting ore has been opened in the Indiana vein, on Chicago mountain, that assays $2.60 gold and 8 oz. silver per ton, with 4% copper.——E. M. Moscript, owner of the Blue Bird, has granted a bond and lease to A. Morelli.——Charles Taylor has just completed a 5-stamp mill on Ute creek and as soon as sufficient water is available the machinery will be started. It is estimated that there are 100 tons of free-milling ore on the dump.

Idaho Springs, February 26.

GILPIN COUNTY.

(Special Correspondence).—The shaft building on the Alps mine, in the Central City district, was consumed by fire last week. James Williams, the lessee, states that a new building will be constructed at once.——A 3-year lease and bond on the Stewart mine, in Leavenworth gulch, has been secured by McMasters Brothers. The shaft is down 80 ft., exposing a 3-in. streak of smelting ore.——H. Altvater & Co. have taken a lease on the O. K. mine. A small engine-house has just been completed, and the shaft, down 180 ft., is to be sunk another 100.——A force of men is being employed at the Senator property and heavy shipments of ore have been started. Returns of 1.1 oz. gold and 17.5 oz. silver per ton are being realized. On an average 25 tons per week are being sold.——Work is to be resumed at an early date on the Gunnell mine, one of the former heavy producers of the district.

Central City, February 25.

LAKE COUNTY.

The north drift from the Dinero adit at Leadville has opened a 5-ft. shoot of ore that assays 100 oz. silver and 2½ oz. gold per ton. John Harrison is superintendent.——Operations have been resumed in the Boulder shaft which was injured by fire some months ago.——The lessees of the Coronado and Hibschle properties are shipping from 25 to 30 tons of ore per day. The ore is being mined on the 450-ft. level and contains a fair percentage of lead.——Shipments have been started from the Little Bob property in South Evans gulch which was recently taken under bond by George Champion and associates.——A body of zinc ore has been opened on the 700-ft. level of the Louisville mine which is being worked through the Yak tunnel and shipping will be resumed in the near future.——The New Monarch mine, on Little Ellen hill, is to be unwatered and a new electric pump installed.

TELLER COUNTY.

A new cross vein assaying about $25 per ton has been cut on the 900-ft. level of the Rexall mine at Victor. The vein is about 3 ft. wide, but no development work will be done on it till the main vein on that level is opened.——Charles Anderson and associates, leasing on the eighth level of the American Eagles property, shipped 25 tons of ore, the return on which amounted to $23 per ton.——S. A. Worcester, operating the Conundrum mine on Gold hill under lease, shipped two carloads of ore, the value of the screenings being estimated at $35 and the coarse ore $20 per ton.——The Petrol Gold Mining & Milling Co. has been organized to take over the holdings of the Papoose Gold Mining Co. on Squaw mountain.——A shoot from 6 to 20 ft. wide has been opened on the 1000-ft. level of the Cresson Consolidated and samples taken across the width of the vein run from $22 to $27 per ton.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The Sara Mining Co. has filed articles of incorporation with a capital stock of $18,000, and will open an old mine in the Webb City camp which has been idle some time. A mill is on the property and operations will be started as soon as the mine is drained.——The Fullerton Mining Co. has recently sold to Frederick Cook and associates an 80-acre tract in the Prosperity camp for a consideration of $70,000. The land adjoins the Ground & Irwin tract.——The mill at the Weaver

Tri-City mine, northwest of Carthage, is idle for the present to undergo extensive repairs made necessary by the slow sinking of the plant, due to the cutting out of a large ore deposit directly beneath it.——The Bohemian Girl is a new 200-ton plant under erection on the Kelley land north of Webb City. Ore here is found at shallow levels as well as in the sheet ground formation at 210 ft. The shallow levels will be left for the present and the sheet ground worked.——The large 500-ton plant of the Hercules company, west of Joplin, in the disseminated ore-field, is now completed and will be started as soon as the ventilation plant is completed.

Joplin, February 25.

MONTANA.

JEFFERSON COUNTY.

(Special Correspondence).—Samples of ore taken from the Montana-Corbin Copper Co.'s properties near Corbin give an assay return of 7.1% copper, about 40c. gold, and over 8 oz. silver per ton. The ore was taken from the cross-cut on the 400-ft. level of the main lead in the hanging wall. It is believed that a much better quality of ore will be found on the foot-wall side of the vein, as on the 235-ft. level where the orebody was fairly well opened the best assays were obtained there. On that level there is 2 ft. of high-grade ore.——W. C. Hosking, superintendent for the Calumet-Corbin company, reports that the company which was formerly held by Michigan capitalists is now controlled by St. Paul and Duluth people who propose to start active development work at once.——W. Q. Ranft, president of the Robert Emmet Copper Co., and Robert McArthur, consulting engineer, recently made an examination of the property in the Corbin-Wickes district. Preparations have been made to resume work on the vein eastward on the 350-ft. level where a good body of high-grade ore was opened lately. Sinking is soon to be resumed with the intention of going to a depth of 500 ft. before opening another level. The Robert Emmet is now supplying power from its electric plant to the Blue Bird mine and to the Amazon-Montana mine which is operating the Silver Star property, a mile and a half south of the Emmet.

Corbin, February 25.

SILVER BOW COUNTY.

(Special Correspondence).—The west cross-cut on the 1800-ft. level of the Colorado mine of the Davis-Daly company at Butte, is about 150 ft. from the main vein. At the present time a drift is being run on the small vein a short distance from the shaft which has been opened for a distance of about 150 ft. This is from 6 to 20 in. wide, and assays 2 to 4½% copper.——A vein about 3 ft. wide which assays 40% zinc, 40c. gold, and 8 oz. silver per ton, is being opened on the 1800-ft. level.——The ore on the lower levels of the Butte Coalition is reported to be improving. On the 1700-ft. level of the new vein opened on the 1500 and 1700-ft. levels, a 26-ft. orebody is said to average 7% copper. At the present time the company is producing about 4,100,000 lb. copper per month.

Butte, February 25.

NEVADA.

CLARK COUNTY.

(Special Correspondence).—The Quartette company is operating to a depth of 1200 ft. with good ore opened on the lower levels. The 40-stamp mill and cyanide annex are operating at full capacity and the monthly production of bullion is increasing.——The Spokane-Searchlight has opened ore to the 300-ft. level and is arranging to sink the shaft to water level. It is expected that the 10-stamp mill will be in operation soon. Richard Lloyd is manager.——Driving from the 300-ft. point on the New York Searchlight is progressing rapidly, and some good ore has been opened. This property is one of the best equipped in the district.——The Homestead properties are idle as far as the parent company is concerned though several parties of lessees are working with good results.——The 600-ft. shaft of the Philadelphia-Searchlight is being repaired for the resumption of activities, and it is reported that a diamond-drill will be installed.——The shaft of the Lenape Gold & Copper Mining Co. is down over 400 ft. The quartz vein was cut on the 200-ft. level, but it is expected to enter a body of copper ore near the 500-ft. point.——The Searchlight Mining & Milling Co. has resumed operations.

Searchlight, February 26.

The Knight mill, erected by the Joshua Hendy company on the Homestead Mining & Milling Co.'s property, has been completed and is now running on custom ore. The mill is fitted with a crusher and three 1000-lb. stamps and will treat from 10 to 15 tons per day. The company is to erect a cyanide annex at once.——The Perkins lease, on the Homestead property in the Searchlight district, is sinking on an 18-in. stringer below the 50-ft. level and has sent 20 tons of ore to the Knight mill.——A carload of ore has been forwarded from the I. X. L. lease to the Needles plant and the lessees have another 100 tons ready for shipment.

ESMERALDA COUNTY.

(Special Correspondence).—Reports by the manager of the Florence Goldfield mine indicate that both mine and mill are making an excellent record of production and treatment. A return to direct amalgamation has resulted in saving fully 40% of the gold in amalgam, and the cyanide feed is held at an average of $8 per ton. The tonnage of concentrate has been materially reduced, effecting a corresponding economy in costs of transportation on the latter product. T. G. Lockhart, president of the Florence company, returned to Goldfield to attend the annual meeting at which a dividend of 10%, amounting to $105,000, was declared.——On the Combination Fraction sinking is in progress in the main shaft, and stations will be cut soon from which the work of exploring proved veins will be carried on at the 750 and probably at the 800-ft. levels.——The return from a shipment of 17 tons of ore from the Campbell lease on the Black Butte showed an average gold content of $170 per ton. This ore was taken from a winze sunk from the upper adit at a distance of 75 ft. from the portal. The vein has been cut in the lower adit by the lessees, and the company is now developing and driving for the same orebody on the north side of the hill.——A continued improvement is shown in the workings of the Gold Bar, where ore of shipping grade has been exposed by the lessees on the 150, 200, and 300-ft. levels. A shipment of the ore has been sent to the smelter, consisting of two carloads which is expected to return fully $60 per ton.

Goldfield, February 26.

The Sandstorm-Kendall consolidation is being carried out. The Cook bank will bring suit in foreclosure after which the two properties will be sold to George Wingfield for the amount of the indebtedness, $53,000, and a new company will be incorporated to take over and operate both, the stock of the new concern to be assessable.——Driving continues on the Nancy Donaldson in the eastern part of the district.——The shaft of the Yellow Tiger is being unwatered to the 700-ft. level from which point development will proceed.——On the Atlanta the vein cut from the Maloney shaft at the 630-ft. level is yielding low assays.——The Lincoln Goldfield lease on the Combination No. 2 is being opened by a cross-cut at a depth of 600 ft. from the Moore shaft.——Lessees are still taking small quantities of ore from the Daisy and occasional shipments are made from the Goldfield Belmont.——A raise from the lower adit on the Black Butte Consolidated is being driven for the rich ore-shoot opened above.

STOREY COUNTY.

The retimbering in the Ward shaft near Virginia City which has caused so much trouble recently has been completed and work is centered on the 2100-ft. level. A new station is being cut at the 2475-ft. level, and two pumps each, having a capacity of 2000 gal. per minute, have been ordered.——The face of the cross-cut on the 2300-ft. level of the Mexican mine is in quartz from which low assays are being obtained. The work on this level that is being done jointly by the Ophir and Mexican companies has opened the shoot for a distance of 250 ft. along the vein and 50 ft. across it.——The old south drift on the 1750-ft.

level of the Consolidated Virginia has been reopened and cleaned out for a distance of 530 ft. On the 1800-ft. level 202 carloads was stoped averaging $10.24 per ton.

NEW MEIXICO.

SIERRA COUNTY.

(Special Correspondence).—The Black Range district is situated in the northwest portion of the county which the mountains cross in an almost north and south course. The mining district proper is from 15 to 18 miles in length and from 4 to 6 miles in width. Locally, the term Apache district is also used to designate the extreme south end, but there are not actually two portions, for the Apache district, so called, merges imperceptibly into the Black Range district north and the two form and properly take the name of the Black Range. The most used route into the district is by good wagon-road from Engle, a point on the El Paso branch of the Santa Fe railway, about 50 miles from Chloride, the main town of the district and the end of the stage route. A daily Government mail-stage, carrying passengers, runs to and from Engle and connects with

U. S. Treasury Shaft.

the Santa Fe trains to Albuquerque on the north and El Paso on the south. This route crosses the Rio Grande about 14 miles from Engle. The other route is by way of Socorro and Magdalena and is about 20 miles longer than the other one, but there are no rivers to cross and the road is excellent all the way, with an easy grade. The average altitude of the Black range is between 4000 and 6000 ft., although some of the peaks attain an elevation of 8000 to 10,000 ft., but the entire range is of easy access. The district is covered with a liberal growth of piñon, scrub oak, and pines, and there is ample water for all mining, milling, and domestic purposes. The principal property in the south end of the district is the old United States Treasury mine, a patented property which was located many years ago and from which a considerable production was made. It contains a large amount of low-grade milling ore and has recently become the sensation of the district by reason of extraordinary high-grade discoveries. Recent shipments from this property to the smelters at El Paso assayed 104 oz. silver and 10.14 oz. gold, and 153.2 oz. silver with 18.32 oz. gold per ton. It was this discovery which started the inrush and resulted in the rejuvenation of the district. It is understood that a big mill will be installed at this property during the coming year. In the north end of the district, in the vicinity of the new town of Fluorine, considerable shipping ore has been exposed, some of it assaying as high as several hundred dollars per ton. In one vein, 3 ft. wide, in the Great Republic mine, which is the biggest mine in the north end of the district, there is a showing of ore which averages close to $60 per ton across the entire vein. In the central and north-central portion of the district the Dreadnaught group shows both milling and shipping ore, and the old Ivanhoe mine also contains shipping and milling ore.——The Silver Monument mine, one of the copper-silver properties, has had something over 2000 ft. of development and is one of the best properties in the camp. It is completely equipped with machinery and the development work thus far done has exposed large quantities of ore.

Chloride, February 25.

OKLAHOMA.

OTTAWA COUNTY.

(Special Correspondence).—A new discovery has been made in the Oklahoma field three miles northwest of Miami on the Ensworth land, the main orebody being opened at a depth of 72 ft. Both lead and zinc are found comparatively free from iron which is usually present in this part of the field. Hand jigs will be used for the present to clean the ore. The most important feature of the find is that it occurred in new territory and a number of drill-holes in the same vicinity also cut the deposit.——While the Miami Yankee company is engaged in sinking to a lower level the mill has been leased to the Willow Branch company to clean its ores. The Miami Yankee formerly operated at a depth of 90 ft., but is sinking the shaft to 140 ft. where a better run of ore is found. A fissure vein containing almost pure zinc blende was found and a winze sunk on it which led the company to deepen the shaft.——To the north, at Lincolnville, the Tennessee Metal Producing Co. is making preparations for a more extended development. It has taken over the Mascotte property, is building a tramway from this shaft to the Tennessee mill, and erecting a power-plant and derrick at the Mascotte shaft. The mill on the original property is being overhauled and oil burners installed.

Miami, February 26.

TEXAS.

EL PASO COUNTY.

(Special Correspondence).—More mining development is now in progress in the Quitman, Chinati, Davis, and Van Horn ranges of mountains than for many years. Many of the older prospects which have been idle for some time are being reopened with good prospects of becoming profitable producers of ore. It is announced that the Republic Mining & Milling Co. will soon start the mill and concentrating plant at its Bonanza mine in the Quitman mountains for the treatment of lead-zinc ore. William B. Phillips, director of the Bureau of Economic Geology of the University of Texas, who recently made an examination of the territory around the Bonanza mine, says: "It is a copper district of considerable promise, and very little attention need be given to the lead ores. Several cars of copper ore have been shipped, and the average of the selected material assayed 18% copper and $2 gold per ton. The best ore that has been taken out assayed 24% copper, 39 oz. silver, and 1.32 oz. gold."——A. D. Hudson, who is operating a turquoise mine in the Van Horn mountains, near the town of Van Horn, recently cut a vein that assays high in gold. ——The Little Lightning Copper Co. recently shipped several cars of high-grade copper ore from its mine in the Quitman mountains to the El Paso smelter. The company has increased its force of men and is getting out considerable ore.——A large body of ore that assays about 50 oz. silver per ton has been found on the claims owned by John Gilcrease, near the new station of Lasca on the Southern Pacific railroad. T. D. McKinney is superintendent.——A silver claim, situated in the foothills of the Quitman mountains, is being developed under the direction of John Moffet. The property is owned by Thomas O'Keefe, of El Paso.

El Paso, February 26.

UTAH.

JUAB COUNTY.

The shaft at the Tintic Central property at Tintic is now down 555 ft. The ground is loose and considerable water has been met, causing the work to advance rather slowly. A. N. Haldaway is manager.——On the 500-ft. level of the Iron Blossom No. 1 a drift has been driven 35 ft. from the station that was recently completed.——Four carloads of ore per week is being shipped from the Gemini and Ridge & Valley mines and a 500-gal. pump is to be added to the equipment. Jackson McChrystal is manager of both properties.——Two large boilers and a new hoist have been ordered for the Chief Consolidated mine and will be installed within the next 60 days.——During February 16 carloads of ore was shipped from the Eagle & Blue Bell mine. This was taken largely from the shoot recently opened on the 1200-ft. level. William Owens is superintendent.——Electric pumps capable of handling 1000 gal. per minute have been ordered by the management of the Centennial Eureka mine and will be installed on the lowest level of the property. Machinery for the new power plant is being shipped in and the work of construction is advancing rapidly.——A whim has been ordered for the Tintic Humboldt claim and sinking will be resumed at the 800-ft. level.

Conditions at the Chief Consolidated mining properties are improving. During the past week the management loaded nine cars of ore within seven days with high-grade silver-lead ore, mined from above the 1600-ft. level. Shipments are now netting the company above $30,000 per month, and this earning will be doubled during the coming summer months. Chief Consolidated is counted upon to become one of the regular dividend payers.

SALT LAKE COUNTY.

The Bingham Mines Co., Ltd., operating at Bingham Canyon, has issued its first annual report for the year ended December 11, in which it states that during the year $331,000 worth of the Bingham Consolidated Mining & Smelting Co.'s bonds have been cancelled, reducing the outstanding debt to $572,000, that there is a balance of cash and loans on hand of $10,111, and that the net profit for the year amounts to $55,774.——The Utah Metal Mining Co. has filed a suit in the United States Circuit Court against the New England Gold & Copper Co. to recover $1,350,000 for ore alleged to have been extracted from the property which was purchased from the Bingham Standard company. The plaintiff company at the same time filed a suit in equity against the New England company to preserve the property involved in the suit.

SUMMIT COUNTY.

The Daly West property is shipping considerable zinc concentrate, having sent out over 500 tons in January, 1100 tons in February, and is planning for an increased output this month. The annual meeting of the Daly West stockholders resulted in the re-election of the directors.——The bulk of the work at the Uintah Treasure Hill mine is now being carried on at the 250 and 600-ft. levels and is opening some fair ore.

WASHINGTON.

SNOHOMISH COUNTY.

(Special Correspondence).—The transportation problem, which has been the most difficult one confronting owners of mining property in the Sultan district, and which has greatly retarded one of the richest of the county's districts, is about to be solved. The Sultan Railway & Power Co., which, during the past three years has expended $60,000 in the development of a water-power at the head of the Sultan canyon, is under contract with the Government to commence construction of its electric road between the Great Northern railway and the power-plant before July 1. It is learned that Boston and other Eastern capitalists interested in the Forty-Five and other mining properties of the district are arranging to build an extension of this line up the valley, and that operations are to be resumed at the Forty-Five on a larger scale than ever before. The distance from the Great Northern to the power-plant is sixteen miles, and from the latter point to one equally accessible to the Forty-Five, North Coast, Little Chief, and Blackman properties it is about eight miles. The estimated maximum of the power-plant is 45,000 hp., the dam being 125 ft. high.——The North Coast Copper Co., at its annual meeting last week, authorized the purchase and installation of a 4-drill water-power compressor plant, and extensive development work is to be carried on this season under direction of George C. Clarke. At this meeting J. A. Falconer was elected president.——V. V. Clark, consulting engineer for the Copper Belle Mining & Smelting Co., who has just returned from a consultation with officers of the company in New York, stated that there was no immediate prospect of their smelter resuming operations. The company has expanded $600,000 in development and equipment of its property near Index, including a 100-ton concentrator and a 50-ton oil-burning matte-furnace.——Operations of the Wayside mine, at Granite Falls, which have been conducted for about a year under an agreement between the receiver and creditors, have been suspended and tne mine is flooded. While the big pump was being removed one day last week, the auxiliary pump broke down and the water gained so fast that the crew had to abandon both. No plans for resumption of work have been announced. The last shot put in at the 850-ft. level exposed the best ore that has ever been seen in the mine.

Everett, February 19.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—A new deposit of gold-copper ore assaying about $35 per ton has been cut by the diamond-drill on the ninth level of the War Eagle claim of the Consolidated group at Rossland. A new 5-ft. shoot has also been found on the third level of the Centre Star property of the same group.——The monthly report of the Le Roi No. 2, Ltd., for December shows shipments of 2480 tons of selected ore during that month. The approximate figures for January are 2300 tons. The company has declared a dividend of two shillings per share, payable March 8.——The Blue Bird Mining Co. is to resume work on its property in the south belt in a few days. The property was operated under lease last year and shipped some ore of excellent grade.——A new orebody has been cut on the 300-ft. level of the Inland Empire.——Though shut down several months, the British Columbia Copper Co. during its fiscal year ended November 30, treated 373,336 tons of ore at its Greenwood smelter, producing 6,325,000 lb. blister copper, 18,244 oz. gold, and 64,234 oz. silver. The cost per pound was 9.829c. which included all charges. The net profits for the fiscal year was $236,338, being $142,378 greater than for the same period the previous year. The average price received for copper sold was 13.08c. per lb.——It is understood that the board acting under the Conciliation Act, which was appointed to adjust the difficulty between the company and employees, failed to agree. The majority were against the union and its stand for the closed shop.——Arrangements have been made by A. E. Rand, of Westminster, to reopen the Dundee mine at Ymir. C. W. Riley, of Nelson, will be in charge. To reduce mining and pumping costs work will first be started on an 1800-ft. adit.——A rich shoot of ore from 12 to 14 ft. wide has been opened in the east cross-cut from the shaft on the Queen property at Salmo.——The Canadian Pacific railway will soon start work on its branch line from Elko to meet the line building southward from Golden. This line, 174 miles in length, will open a valley rich in mineral wealth.——The Ikeda Bay mine, on Moresby island, of the Queen Charlotte group, has now been taken on a $250,000 bond by a syndicate of Vancouver capitalists, of which S. J. Castleman is the leading figure. The property was recently examined by A. G. Larson, superintendent of the Le Roi mine, for the syndicate, and a contract for $20,000 worth of diamond-drilling let to O. L. Knight & Co., of Rossland.——The Guggenheim interests are to begin work on their $400,000 power-plant at Concrete. The dam in the gorge on Baker river will be 160 ft. high. When power is available from this plant several large saw-mills, coal and metal mines, and clay and marble beds in the district are to be opened.

Rossland, February 26.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

M. K. SHALER is in New York.

E. R. BUCKLEY is in Colorado.

S. H. BALL has gone to Brussels.

W. F. FERRIER was in San Francisco.

H. V. WINCHELL is at Cripple Creek, Colorado.

E. F. BUACHARD has been at Chicago and Pittsburg.

SUMNER S. SMITH and EROL MACBOYLE have gone to La Dura, Mexico.

ARTHUA HOULE, of Douglas, Arizona, has gone to South Africa on mine examination work.

O. H. BERGSTROM, of Butte, has been visiting Copperopolis and San Francisco. He has gone to Seattle.

JOHN TYSSOWSKI, of the staff of *The Engineering & Mining Journal*, visited San Francisco this week.

FRANCIS A. THOMSON has returned to Pullman, Washington, from a professional trip to Butte and Anaconda.

H. W. HAADINGE is making a professional trip through the Lake Superior copper and Cobalt, Ontario, districts.

GEORGE THOW, of the Paymaster mine at Gold Rock, Ontario, was in San Francisco, on his way to Sonora, this week.

T. A. HARPER and J. A. FORTESQUIEU have gone to Honduras. From there Mr. Harper will go to Alaska to take charge of work for Pearse, Kingston & Browne.

C. O. MOSS, formerly manager for the Kansas City-Goldfield Mining Co., at Goldfield, Nevada, is now superintendent of the Sierra Morena mine, near Paso Robles, California.

C. A. HEBERLEIN has returned to 15 Calle Madrid, Mexico, D. F., from Achotla, Campo Morado, where he has been erecting a smelting plant for the Suriana Mining & Smelting Company.

W. S. HEGEN, who has occupied various executive positions with the Allis-Chalmers Co., has been appointed manager of the San Francisco and Los Angeles branches of this company, with headquarters in San Francisco.

JOHN A. FARWELL, who has for a number of years been secretary-treasurer and sales manager for the J. Geo. Leyner Engineering Works Co., has retired from the company to return to Chicago. His address will be room 305, No. 115 Dearborn street.

Obituary.

DAVID P. CAMERON, who died of diabetes at San Francisco February 24, had been closely identified with the gold dredging industry since the beginning of this branch of placer mining in California. He constructed the first bucket-elevator dredge in the Oroville district, built many of the early dredges installed in the Oroville, Yuba, Folsom, and Calaveras districts. In 1900, with Frank W. and Maurice E. Griffin, he formed the firm of Griffin & Cameron. In 1902 this firm was incorporated under the name of the Western Engineering & Construction Co. At the time of his death he was vice-president and superintendent of construction for this corporation. Mr. Cameron was actively engaged for years in constructing stamp-mills and milling plants, and he erected many of the large plants in Mexico and South America. At one time he held the position of superintendent of construction for Leland Stanford at Palo Alto. He was also associated with the Pelton Water Wheel Co., for which company he installed a large number of plants. Later he became identified with the Risdon Iron Works, superintending the construction of a large number of the early dredges built by that company. Mr. Cameron was a native of Nova Scotia. His knowledge of the construction of stamp-mills, water-power installations, and placer dredges was unusual. He was regarded by all as without a peer in the design and construction of placer mining dredges.

THE ANACONDA COPPER CO. has made a statement to the listing committee of the New York Stock Exchange in connection with its application to transfer its $30,000,000 of capital stock from the unlisted department to the regular side of the Exchange. Heretofore both Anaconda and Amalgamated have been unlisted and regular reports and statements of financial condition have not been required. The statement of the Amalgamated has now been submitted to the listing committee, but the application will not be acted upon until February 9. The data given by the Anaconda is interesting, as this was the nucleus around which the Amalgamated was originally constructed, and it is soon to absorb in turn not only Amalgamated but practically all of the larger mines of Butte. The Anaconda company's holdings today consist of 1168 acres of mining ground in Silver Bow county, Montana, with mines operated through 11 shafts, all save one being reported to be more than 2200, and one as much as 2900 ft. deep. Development on the lower levels is described as being better than could have been expected from indications above. In addition to the mining property in Butte, the Anaconda owns more than 12,000 acres of land in Deer Lodge county, 2600 acres of coal land in Cascade county, and other scattered lands. The Washoe smelter is held by lease from the Washoe Copper Co., the lease expiring in about two years. The company also owns 51% of the stock of the Anaconda & Pacific Railway Co. and 30,471 acres of timber land in Ravalli county, Montana. The coal properties mentioned are at Belt, Montana, and have been in operation for many years. In addition to all of the above, the company owns practically everything in the town of Anaconda; electric light plant and railway, water works, hotel, and most of the town-site. The production of the Anaconda Copper Co. for 1909 was: copper, 75,860,194 lb.; silver, 2,363,184 oz.; gold, 7466 oz.; the profit and loss account for the first six months of 1909 shows a net profit of $1,221,910, while the balance sheet of the same date shows assets in mines and mining claims, coal properties, saw-mills, water works, etc., of $23,555,586, and investments in railway and other stocks amounting to $534,113. For the first time Anaconda and Amalgamated have taken the public into their confidence. Amalgamated is soon to pass into history, and of its memory, like Caligula, as described in the small boy's essay, "the less said, the better." The Stock Exchange has not yet made public the statement of the Amalgamated company.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

LOCATION OF PLACER CLAIMS—RIGHTS OF INNOCENT LOCATORS. Where the location of an association placer mining claim was decided to be invalid because of the fraud on the part of some of the locators, if the required assessment work had been kept up and the law and district regulations complied with, the locators who were not implicated in the fraud, but acted in good faith, had the right to select and hold their proportionate part of the land within the limits of the association claim.

Cook *v.* Klonos, 168 Fed. 700, March, '09.

INJURY TO MINE—RIGHT OF LESSEE TO RECOVER. A lessee of a mine may recover for injuries thereto by a third person though the injury exceeded the value of the lease, so as to give a right of action to the lessor. Thus where a third person, by a breach of a contract to drain a mine prevented it from being worked, the fact that the cost of restoring the mine exceeded the value of the lease, was not sufficient to prevent a recovery by the lessor.

Carter *v.* Cairo, etc., R. Co. (Ill.), 88 Northeast. 493, Apr., '09.

INJURY TO MINE—MEASURE OF DAMAGES. A railroad company in consideration of being permitted to build an embankment over the mouth of a mine which was leased to a third person, agreed with such lessee to keep the mine properly and sufficientiy drained. By reason of a breach of the contract and the failure to perform its duty in keeping the water out the mine was flooded. The measure of the lessor's damages in an action to recover for the injury was held to be the cost of restoring the mine to its condition before it was damaged; but where such cost exceeded the fair cash market value of the unexpired term of the lease, then the lessee could only recover the fair cash market value of his leasehold.

Carter *v.* Cairo, etc., R. Co. (Ill.), 88 Northeast. 493, Apr., '09.

LEASE OF MINES—RECOVERY FOR BREACH. The owners of a lease of mineral lands contracted with certain persons by which they agreed to sub-lease such mineral land to them for ten years if they would develop paying ore. In an action for damages on a breach of such lease, the fact that such sub-lessee at the date of the contract had a good and subsisting lease of the land which the sub-lessors knew was subject to forfeiture for their failure to do the work required, was not sufficient to prevent such sub-lessors from recovering from the sub-lessee damages for failure to comply with the contract caused by the subsequent forfeiture of their lease.

Ragland *v.* Conqueror Zinc Co. (Mo.), 118 Southwest 1194, May, '09.

STATUTE REGULATING THE USE OF EXPLOSIVES IN MINES. The statute of New York regulating mines and the use of explosives, authorizes the commissioner of labor to see that every precaution be taken to insure the health and safety of employees in mines and quarries, and prescribe rules and regulations therefor. Under this authority the commissioner of labor prescribed certain regulations as to the use of a fuse and the method of igniting the same. The statute also provides for the explosion of gas by electricity with electric exploders. It was accordingly decided in an action for damages for the death of a miner, where the electric exploders were used instead of a fuse as required by the commissioner of labor, that the regulation requiring the use of safety fuse did not apply where the blasts were exploded by electricity. It was also decided that the owner of a quarry was not liable where the shots were prepared for exploding by electricity in the usual manner, but two of the blasts were exploded by a flash of lightning during a thunder storm which resulted in the injury complained of.

Bacceli *v.* North River Stone Co., 118 N. Y. Sup. 29, June, '09.

STATISTICAL RECORD OF THE PROGRESS OF THE UNITED STATES, 1800-1908. Department of Commerce and Labor. Pp. 72. Washington, 1909.

MINERAL PRODUCTIONS, COUNTY MAPS AND MINING LAWS OF CALIFORNIA. Bull. 56. California State Mining Bureau. Pp. 100. San Francisco, 1909.

MERCURY MINERALS FROM TERLINGUA, TEXAS. By W. F. Hillebrand and W. T. Schaller. U. S. Geol. Surv., Bull. 405. Pp 174. Washington, 1909.

RESULTS OF SPIRIT LEVELING IN OHIO, 1898-1908. Compiled by S. S. Gannett and D. H. Baldwin. U. S. Geol. Surv., Bull. 411. Pp. 147. Washington, 1909.

FUEL TESTS WITH HOUSE-HEATING BOILERS. By J. M. Snodgrass. Bull. 31. Univ. Illinois Engineering Experiment Station. Pp. 108. Urbana, 1909.

RECENT DEVELOPMENT OF THE PRODUCER-GAS POWER PLANT IN THE UNITED STATES. By R. H. Fernald. U. S. Geol. Surv., Bull. 416. Pp. 82. Maps. Washington, 1909.

MINERAL RESOURCES OF THE UNITED STATES FOR 1908. U. S. Geological Survey, Washington, 1909.

Additional advance chapters as follows are now available: Zinc, by C. E. Siebenthal; Cadmium, by C. E. Sieben-

thal; Lead, by C. E. Siebenthal; Quicksilver, by H. D. McCaskey; Copper, by B. S. Butler; Gold, Silver, Copper, Lead, and Zinc in the Eastern States in 1908, Mine Production, by H. D. McCaskey.

MINERAL DEPOSITS OF THE CERBAT RANGE, BLACK MOUNTAINS, AND GRAND WASH CLIFFS, MOJAVE COUNTY, ARIZONA. By F. C. Schrader. U. S. Geol. Surv., Bull. 379. Pp. 226. Ill., map, index. Washington, 1909.

NEW ZEALAND. PAPERS AND REPORTS RELATING TO MINERALS AND MINING. Comprising statements by the Minister of Mines; Report on the Goldfields; Report on Coal Mines; State Coal Mines. Wellington, 1909.

PROCEEDINGS OF THE SYDNEY UNIVERSITY ENGINEERING SOCIETY, 1908. Sydney, N. S. W., 1909.

Containing an elaborate account of the treatment of Broken Hill ores by W. Poole, and other engineering papers.

COAL INDUSTRY OF NEW SOUTH WALES. By F. Danvers Power. Presidential Address before the Sydney University Engineering Society. Pamphlet. Pp. 12. Sydney, 1909.

An excellent discussion of the main economic aspects of an important coalfield by one well qualified to pass judgment.

MINERAL RESOURCES OF ALASKA—FAIRBANKS; YUKON—TANANA; AND LOWER YUKON REGIONS. By L. M. Prindle, F. J. Katz, C. C. Covert, C. E. Ellsworth, and A. G. Maddren. U. S. Geol. Surv., Bull. 379-E. Pp. 181-266, maps. Washington, 1909.

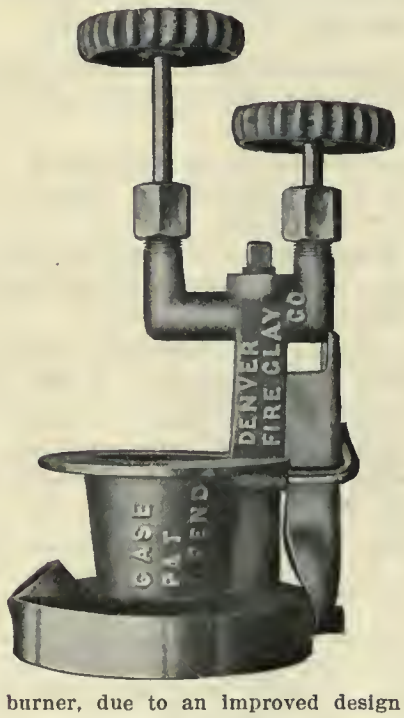
A part of the report on progress of investigations in 1908.

TWENTY-SEVENTH ANNUAL COAL REPORT. Illinois Bureau of Labor Statistics, David Ross, secretary. 8vo. Pp. 443. Springfield, 1909.

This report, which includes complete statistics of production and labor with supplementary reports by each of the mine inspectors, is a standing refutation of the common statement that no office which is 'in politics' can do good work. Illinois statistics of coal production have long been known to be among the best and most complete issued.

A New Burner.

THE DENVER FIRE CLAY CO., Denver, Colorado, is distributing a small pamphlet descriptive of the Case hydrocarbon burner. Great economy of fuel, compactness, uniformity of operation, and freedom from leaks are the strong features claimed for this burner. Its length is less than



any other burner, due to an improved design of mixing chamber. The usual, and nearly always troublesome, needle-valve is dispensed with. The regulation of the flow is accomplished by constructing in the channels between the valve seat and the opening through which the gas is emitted, a groove whose cross section increases proportionately as the valve is opened. The groove is so constructed that the gas on passing through it is reflected from the upper surface of the channel, this surface being exactly perpendicular to the plane of the front of the burner and perfectly centering the opening into the furnace, forcing the flow of gas directly through the centre of the burner.

Commercial Paragraphs.

WALLACE & SUMMERHAYES have been retained as consulting engineers for the Tularosa Copper Co., at Bent, New Mexico.

THE H. W. JOHNS-MANVILLE CO. announces that its Chicago branch has been moved to 27-29 Michigan avenue, and that its Baltimore office, store, and warehouse will, in the future, be at 30 Light street.

PARROTT & CO., San Francisco, Pacific Coast agents of the Grant flaming arc lamp, are distributing a circular announcing the fact that these lamps have been adopted by the lighting company of Bakersfield, Cal., for use in the illumination of the streets and stores of that town.

THE CYCLONE DRILL CO., Orrville, Ohio, has opened a New York office at 1456 Hudson Terminal Bdg. C. H. McCarthy will be in charge. The company reports that its 1909 business showed an increase of 90% and that it is now preparing plans for a large increase in shop facilities.

T. H. PROSKE, Denver, Colorado, recently shipped to the Isthmian Canal Commission for use at the Panama Canal, one D 24 Ajax drill-sharpener for sharpening drills up to 25 ft. in length, and has just shipped to Christiana, Norway, a similar machine for use in the iron mines of that country.

THE SWEETLAND FILTER PRESS CO., Los Angeles, California, now has under construction two Sweetland Type D slime filters of 150 tons daily capacity each, for the Providencia Mining & Milling Co., of Guanajuato, Mexico. Each press will have 30 frames, carrying a 4 by 6-in. filter leaf. Hydraulic devices will be provided for rapidly opening and closing the presses.

The ALLIS-CHALMERS CO. has appointed W. S. Heger manager of its San Francisco and Los Angeles branches with headquarters at the San Francisco office, 160 Second street. Particular attention will be given to the mining and milling machinery department of its business as heretofore. Mr. Heger is well known on the Pacific Coast and the interests of his company will be well cared for under his administration.

The TRAYLOR ENGINEERING CO., which went into the hands of a receiver about the end of last year, due to difficulties contracted during the hard times of 1907-8, reports that a speedy reorganization of its affairs may be expected. Meanwhile its engineering works and shops at Allentown, Penn., have been leased to Bruce W. Traylor, who continues uninterruptedly the manufacture of the Traylor Engineering Co. machinery.

Catalogues Received.

THE SAMSON MFG. CO., 1650 Champa street, Denver, Colorado, 'The Samson Crusher' Catalogue No. 4. Illustrated. 6 by 9½ inches. 16 pages.

A. LESCHEN & SONS ROPE CO., St. Louis, Missouri, 'Locked Wire Rope for Cableways'. A circular giving list prices of locked coil cables and a brief argument in favor of that style of construction. Illustrated. 6¼ by 6¼ inches. 4 pages.

THE GALIGHER MACHINERY CO., Salt Lake City, Utah, Bulletin No. 500. 'The Callow Traveling Belt Screen'. A concise description of this well known device giving details of the latest improved features. Illustrated. 8½ by 11 inches. 24 pages.

THE J. GEO. LEYNER ENGINEERING WORKS CO., Littleton, Colorado. Bulletin No. 1012. 'Tunnel Driving in Colorado'. By H. Foster Bain. A reprint of an article in the MINING AND SCIENTIFIC PRESS. Illustrated. 6 by 9 inches. 8 pages. Bulletin No. 1013. 'The Leyner Cut'. A brief description of a round of holes said to be particularly effective for driving. Illustrated. 6 by 9 inches. 1 page.

EDITORIAL.

JAPANESE laborers, like 'before the war negroes' and 'before exclusion Chinamen', seem likely to go to premium. In the two years ended December 31, 1909, the net excess of arrivals in Japan over departures for the United States, amounted to 7253, according to statistics collected by the Japanese Foreign Office.

ZACATECAS has long been out of favor with capitalists, and the oft-heralded revival of mining has been postponed by the persistent low price of silver. The district, however, has not merited neglect. This seems to be indicated by the promptness with which the custom mill, recently completed near Zacatecas, has been overwhelmed with offers of ore. This fact gives practical demonstration of the possibilities of the district.

SOUR DOUGH bread was as essential as blasting powder in the development of many Western prospects. Time was when every miner was considered to be *ex officio* a competent cook. Conditions have evidently changed, as the Cooks' Association of the Pacific Coast is extending an invitation to mining men to attend an exhibition at the Auditorium March 21 to 26 and see what real cooking is. We would like to think this a recognition of our skill in constructing biscuit, but we suspect instead it is a missionary effort designed to give us new standards.

WIDE difference exists between the desirability of *a* ship subsidy bill, and *the* ship subsidy bill now before Congress. Mr. Halvor Steenerson, Representative from Minnesota, in a speech on the floor of the House the other day, charged that many congressmen had been threatened with defeat in the next election unless they would support the pending measure. This pernicious activity is said to be displayed by the Merchants' Marine League, an accusation which has properly been made the subject of investigation by the Judiciary Committee of the House. A lobby reveals an anxiety on the part of 'special interests' that is enough to give pause in the enactment of any law.

ZINC OXIDE manufacture, described on another page by Mr. William F. Gordon, formerly manager of the Ozark Oxide works, is one of the most interesting of metallurgical processes. Whereas in lead and zinc smelting proper, persistent effort is made to prevent oxidation, and in all smelting furnaces dust is avoided as a plague, in this particular industry and the related manufacture of basic lead sulphate, oxide and dust are the products sought. Zinc smelting in the United States was long considered

to be in a backward state, but it is worth remembering that the process of direct manufacture of oxide was an early American invention, and the later extension of the same principles to the treatment of lead ores at Joplin and of complex Western ores at Canyon City was also an American triumph. Zinc oxide furnaces have even been used by Mr. J. A. Van Mater, in Virginia, for fire concentration of low-grade ore, much as matte smelting is utilized in copper reduction. For Western ore producers the work described by Mr. Gordon is of large interest as pointing a way to handling complex ziney ores.

DEFINITION of industrial terms is to be undertaken by the Division of Industrial Chemists and Chemical Engineers, of the American Chemical Society. A committee with Mr. Clifford Richardson as chairman has been constituted and proposes to organize sub-committees in co-operation with trade organizations. Such terms as petroleum, ether, gasoline, benzol, bronze, steel, portland cement, and others are in current use without exact and authoritative definition. Much confusion results, and much good may well come from co-operative efforts toward uniformity. Correspondence regarding the matter should be directed to Mr. Richardson, 30 Church street, New York.

SUCH A CATASTROPHE as that caused by an explosion of dynamite in the Mexican mine of the Alaska Treadwell, on Douglas Island, Alaska, is rare in recent years. Press dispatches give the quantity of powder as 275 pounds. It may be said that no magazine or temporary storage box for dynamite is maintained near the stations of the Mexican shaft. Evidently the powder was in transit. The principal magazine of the company is in special tunnels 3600 feet distant from the nearest workings. From this magazine it is brought by railroad along the shore of the island to the mines. Subsidiary storage at the Mexican is at the end of a long adit, driven into the foot-wall, on the first level of the mine. The accident occurred on the 1100-foot level. Full details are not available, but the sympathy of the world is drawn to the sufferers in this terrible disaster.

The Comstock Merger.

Announcement is made of well matured plans to effect a consolidation of the group of companies which together hold the total length of the Comstock Lode. This involves a distance of 10,300 feet from the northern to the southern forks. Such a consolidation is an economic necessity. The separate operation of the mines is rendered extremely difficult owing to the serious problems of drainage and ventilation. Failure to satisfactorily solve these problems has been one cause of the demoralized condition existing on the Lode for many years. The partial successes made from time to time, aided by discoveries of small bodies of good ore, served the purpose of stock speculators and kept alive a unique system of bleeding a certain part of the public by a combination of 'Irish dividends' and 'wash sales'.

By virtue of consolidation the mines can be unwatered and ventilated in accord with a rationally conceived and systematically executed design, and deep mining can be resumed on a large scale. The splendid work done by Mr. Whitman Symmes, in the Mexican and Ophir mines, has pointed the way to engineering success, and to intelligent prospecting based upon the recognized geologic features of the Lode as shown by his remarkable discoveries of ore outside the main fissure of the Comstock vein. This practical demonstration has been of great assistance to Mr. Franklin Leonard, Jr., through whose efforts the consolidation is being brought about. The most interesting feature of the announcement, which means so much for Virginia City and for the State of Nevada, is the high financial standing of the men identified with the new order of things. These details will be found in our news columns. The statement that the merger has been effected is premature, however. Even the plan of consolidation has not yet been divulged. That will be announced in a circular to the stockholders in the several companies at a later date. A syndicate was formed some time ago to purchase floating stock of the companies on the Lode. As a result, large holdings have been acquired, amounting to the control of several of the mines. This syndicate included Messrs. Adolph Lewisohn, Ernst Thalmann, A. L. Scheuer, and others. A committee of stockholders now requests that shares be deposited with the Crocker National Bank, in San Francisco, or the Bankers' Trust Company, of New York. Negotiable certificates of deposit will be issued for such shares, which can be traded in the same as stock. Shares may be deposited up to April 15, inclusive, and the plan of consolidation will be announced at some period between that date and August 1. The depositors then have thirty days within which to accept or reject the plan, and the shares may be withdrawn on surrender of the trust receipt, without expense to the holder. Under such circumstances it would give to the shareholders a material advantage, unaccompanied by risks, to deposit their stock, so as to stand in line for benefits that might accrue to the first comers. The committee further states that if the San Francisco Stock Exchange should decline to recognize the banks' receipts as good delivery, an arrangement will be made with one or more firms of brokers to furnish the actual shares to any person desiring to deliver them to buyers. No effort is made to tie up anyone's stock for the purpose of preventing a free sale.

A rejuvenation of the Comstock Lode would be as gratifying an event as the waste of opportunity for decades has been disgraceful. No one believes that the Comstock Lode is exhausted; everyone believes that it may become a great producer. This was the foundation on which the stock-gamblers rested their nefarious business; and the same conviction now leads men of national standing in finance to open the way for a new career of mining on the most famous deposit of silver-gold ore in the United States. It is interesting to observe that the limitation of holdings to small areas on this historic lode has long helped to delay its larger development, and that after more than forty years it is just coming to a condition for economic mining such as the great new copper properties of the Southwest enjoy from the beginning.

Smelter Fume Compromise.

Previous mention has been made in these columns of the rational procedure of both the farmers and smelters in Shasta county, California, in their negotiations for a settlement of the contest over smelter fume. The tentative agreement between the Shasta County Farmers' Protective Association and the Mammoth Copper Company, a subsidiary of the United States Smelting, Mining & Refining Company, was clinched on February 23, when the farmers signed the contract amid much enthusiasm. This happy termination of a dispute that originally threatened to produce bitter legal warfare, is in the last analysis a tribute to the good sense displayed by Judge J. A. Marshall of the United States Circuit Court of Appeals. In the group of cases arising under similar circumstances in Utah, brought by James Godfrey *et al.* against the American Smelting & Refining Company, the United States Smelting Company, and others (158 Fed. 225), the demands of the farmers were originally recognized by the granting of injunctions. Later, after demonstration by the United States Smelting Company that it had installed equipment capable of removing the obnoxious sulphuric anhydride from the fume, a decree was granted permitting the resumption of operations at the Bingham Junction plant. Since that time, nearly eighteen months ago, the lead roasters and blast-furnaces have been running without causing damage to the surrounding forms, and under a modified decree in July 1909 the operation of the copper furnaces has been permitted. With this object lesson the farmers in Shasta county have become convinced that the spirit of live and let live can be given another practical application. This wise action will doubtless establish a precedent that will be followed elsewhere when like troubles arise. The attorneys in the case, Mr. T. W. H. Shanahan for the farmers, and Messrs. Alfred Sutro and D. G. Reed for the smelter, deserve congratulation for the manner in which they have guided their clients to a compromise.

The contract now ratified requires the Mammoth Copper Company to complete a bag-house and equipment for neutralizing the fume, and to put these into service within ninety days, and the contracting parties have agreed that the Farmers' Protective Association shall bring a friendly action in the Circuit Court, stipulating a form of decree, stated in the same terms as that handed down by Judge Marshall, that will be accepted as binding upon both. This sets forth that "all the sulphuric acid arising from the operation of the copper smelter, and contained in the fumes and gases from its copper furnaces, shall be neutralized by the introduction into said fumes and gases before reaching the bag-house hereinafter mentioned, of a sufficient quantity of zinc oxide or other effective agent, so that after such treatment no sulphuric acid shall exist in a free state in said gases." The decree further states that all solid matter held in suspension, including copper, lead, arsenic, and soluble sulphates emitted from the furnaces, and sulphates resulting from the neutralization of the sulphuric acid, shall be filtered out, and that the gases after passing through the bag-house, when discharged into the atmosphere, shall not contain more than seventy-five hundredths of one per cent of sulphur dioxide by volume. This requirement, of course, necessitates extensive dilution of the escaping gases. These are, furthermore, to be so discharged as to insure diffusion, preventing injury to crops, trees, or other vegetation, or to domestic animals, and the surrounding population. The farmers are also given the right to appoint a committee of three, with experts, to visit the smelter at any time to ascertain whether or not the stipulations made in the court decree are being observed. The smelter is likewise conceded the privilege of making inspection of the farms to ascertain whether damage is being caused by fume issuing from its stacks. In case of supposed injury from fume any member of the Association is required to notify the manager of the smelter so that suitable action may be taken to prevent its continuance. The contract expressly states that none of the provisions of the decree shall operate as a waiver or estoppel in the matter of damages claimed as arising prior to the installation of the equipment specified.

The smelter at Balaklala is not a party to the contract just signed, but negotiations are pending which will evidently lead to a somewhat similar *modus vivendi*. It is understood that the electrostatic precipitation system of Mr. F. G. Cottrell, which has been tried at the Selby smelter on San Francisco Bay, will be applied at Balaklala, so that no further contest over smelter fume is anticipated in Shasta county. The suppression of the smoke difficulty is thus finally accepted by the Shasta smelters as the solution of the problem. This is in contrast with the outcome of the struggle at Anaconda, Montana, where the injunction against the Anaconda smelter was dissolved by Judge William H. Hunt on the ground that the company had done all that modern skill could accomplish to abate the nuisance, and that the greater number of persons dependent upon the copper industry necessitated the continuance of operations. In fairness it must be said that the magnitude of the Anaconda smelter renders the problem there much more difficult. That elimination of the objectionable substances from the smoke of a relatively small smelter is economically possible does not prove the applicability of similar means to such enormous volumes as would require treatment at the Montana works. Nevertheless the decree of Judge Hunt was not accepted as conclusive and appeal has been taken to the Circuit Court of the ninth circuit, and the case will shortly be tried in San Francisco. The testimony in the case of Bliss *v.* Anaconda, above referred to, is the most voluminous ever taken in any litigation over smelter fume, comprising over twenty-five thousand typewritten pages. The technology of the subject has been reviewed in the most elaborate manner in the evidence submitted, and the ultimate decision of the courts in this instance will have a powerful influence on the future relations between the farmers and the smelters. The agreement effected in Shasta county, however, based as it is upon a Federal Court decree, will establish a precedent inclining others to compromise rather than pursue the expensive and harrassing course of litigation. It is the way of peace, economy, and goodwill.

Hoag District, California.

Written for the Mining and Scientific Press
By Norman C. Stines.

In the extreme northeastern corner of Modoc county, California, is a district 1½ miles wide by 4 long, known as the Hoag mining district. It extends on the north to the Oregon line, and on the east to within seven miles of the Nevada line, and is more definitely described as occurring in sections 1, 2, 11, 12, 13, and 14, T. 47 N., R. 15 E.; sections 35 and 36, T. 48 N., R. 15 E.; and what would be, were it surveyed, section 31, T. 48 N., R. 16 E., and sections 6 and 7, T. 47 N., R. 16 E., M. D. B. & M. It is, by the shortest route, 52 miles from Alturas, the county seat of Modoc county, which is the present terminus of the Nevada-California-Oregon railway. The other terminus of this line is at Reno, Nevada, distant 185 miles southeast. The nearest communities (each of which is reached by a good wagon-road), are Fort Bidwell, 12 miles distant in Surprise valley, and New Pine Creek, in Goose Lake valley, 8 miles distant.

Gold and silver-bearing quartz was first discovered in this district 30 or 40 years ago by an army scout named Hogue. Before he could locate anything he was killed in a skirmish with the Indians. After his death no further attention was paid to this area until 1905. In that year a sheep-herder brought to Fort Bidwell some quartz specimens showing free gold. J. O. Kafader, with others of Fort Bidwell, after learning in what region the specimens were found, came to the mountains, and, after several days spent in prospecting, located the ground now held by the Bidwell Discovery Gold Mining Co. This started a local rush, and by the following summer, when practically the whole area had been located, the Hoag mining district was organized.

The district is an area of eruptive rock, composed of rhyolite, quartz andesite or dacite, andesite, and basalt, occupying the summit of the Warner mountains, a chain varying in altitude from 6000 to 9000 ft., extending south from Oregon about 60 miles into California, from which State they pass into Nevada. In California these mountains run a little east of south, and separate the Goose Lake valley, on the west, from Surprise valley, on the east. The eruptives have been forced through the flat-lying basaltic flows which form the crest of these mountains. They really make, as it were, an island of eruptive rocks in a sea of basalt.

Ample evidences exist that this area occupies an anticlinal fold. To the east on Mt. Bidwell, the basaltic rocks dip sharply to the northeast: on the north these same rocks dip to the north, the angle decreasing until at Warner, 22 miles distant, they are nearly flat; and to the west, beyond Goose lake, the strata dip southwesterly. The opportunities for observation on the south are obscured by dense forests and its accompanying heavy soil. The axis of the anticline runs N.50°W.

Some distance north of the district, at what is known as Twenty-Mile creek, the stream has cut a canyon through the flat-lying basalt. The section so exposed shows that the basalt accumulation was a result not of one flow but of several distinct ones. A period of flow was followed by one in which only tuffs were formed; that, in time, was followed by another flow. The basalt varies in thickness from 4 to 100 ft. or more, and the separating tuffs, of a light gray to brown color, vary in thickness from a mere seam to several feet. Whether or not a period of basaltic flow was followed by one of erosion before the tuff was deposited could not be determined from the limited chance for observations. In two places, lying between the tuff and the underlying basalt, were found thin horizontal lenses of brown clay. There are three of these tuff deposits exposed, and there were at least four flows of basalt. Toward the eastern base of Mt. Bidwell are seen evidences of tuffs, their position marked by talus. At the base of the range to the west, that is, on the east side of Goose lake, underlying and conforming to the basalt, are layers of fine-grained conglomerates and solidified volcanic mud-flows. These strata, or their continuations, are exposed in Cedarville pass, a low gap in the Warner mountains, 25 miles south of the district. Here the dip is to the southwest.

Scattered over the surface of the basalt, north and east, are many fragments of obsidian. These vary in size from sand-particles to pieces weighing 10 lb. They are wholly absent from the surface of the dacite, andesite, and basalt dikes. Their occurrence, with vesicular fragments of a basic rock, at least suggest that both are products of volcanic explosion.

The eruptions forming this 'island' vary from the most acidic to a very basic one. No direct evidence, further than that of inclusions, mentioned below, was observed to fix the relative age of these rocks, but the basalt dikes are probably the oldest, and were followed successively by the andesite, dacite, and rhyolite. The basalt occurs as dikes in the southern end of the district, comprising about one-eighth of the total area. It is a fine-grained rock, not much altered, showing long, lath-shaped crystals of augite in a ground-mass of a mixture of the same mineral with a basic feldspar, probably labradorite. Toward the northern boundary of this basalt were found a few hand specimens which showed quartz phenocrysts, much corroded. In the 'wash' from this area are found rocks the originals of which were sandstones, although they are now thoroughly metamorphosed. Their presence can only be accounted for by their having been broken from the rocks through which this basalt has passed, being brought up as inclusions. Later erosion exposed and liberated them.

Just north of the basalt is a small area of andesite. On the contact with the basalt this andesite has been vesicular, the vesicles having since been filled with quartz. These amygdules are clearly secondary in origin. The principal minerals of the andesite are phenocrysts of a basic feldspar, probably andesine, and altered augite. These phenocrysts occur in a fine-grained ground-mass in which the minerals were undetermined. Near the contacts and in proximity to the veins, the rock takes on a much greener appearance, due to alteration of the augite and to the formation of chlorite.

Next on the north is the dacite. This occupies about 75% of the area of the district. Economically it is the most important. It occupies all of the northern part of the district and is only lost when it passes under the basaltic flows. It is found both as a compact porphyritic rock and also brecciated. This large mass of dacite has been extensively fractured and later altered, the fracture or shear-zones having been almost completely silicified. The silicification has been so extensive that diligent search over a considerable area was necessary before a hand-specimen which did not show secondary quartz could be found. It is along these shear-zones that the rock takes on the appearance of a breccia. The fractured pieces of the dacite, from small cubes to those weighing several tons, have been consolidated into a solid mass by the silica. Fresh specimens of the dacite are light colored and show hexagonal phenocrysts of quartz, more or less corroded, and a plagioclase feldspar, andesine or acid labradorite, in an almost wholly vitreous ground-mass. Small dark crystals of some ferro-magnesian mineral occur disseminated sparingly through the ground-mass.

Mineral Hill, on Which the Claims are Situated.

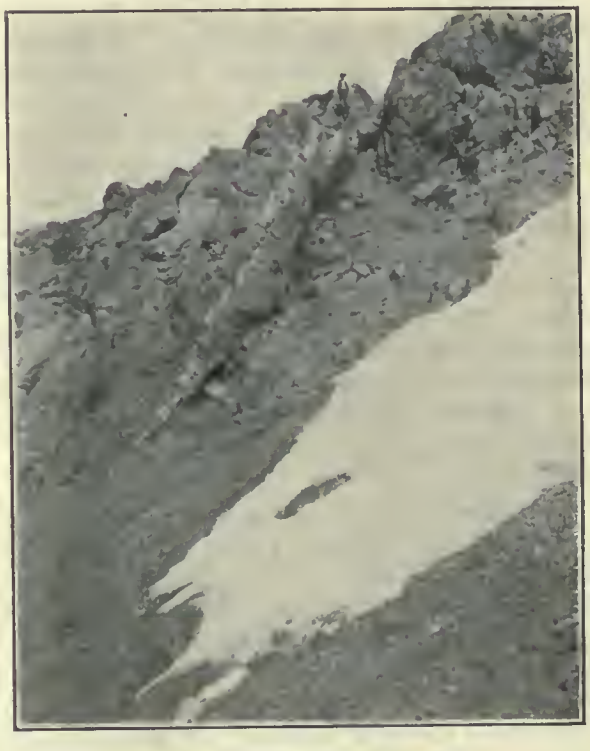
There are a number of rock inclusions, small and large. The smaller ones are completely altered, and it is practically impossible to determine their original character. Some have now the characteristics of a quartzite, and were probably fragments broken from a sandstone. Others are very dark, almost black, and extremely hard, having somewhat the appearance of the andesite and basalt dikes. They are probably fragments of those rocks, as these inclusions are more numerous in the southern part of the mass. These foreign masses were broken from the rocks passed through, and were brought up by the dacite.

On section 1, T. 47 N., R. 15 E., are examples of inclusions of large size. Here whole rock-masses have been brought up and exposed at the present surface, overlying the dacite. The inclusion still retains plainly the evidences of its former sedimentary character, namely, bedding planes; and cleavage planes have been developed also.

On the highest peak of this area, Yellow mountain, 8540 ft. high, is a capping of rhyolite. It is a light colored rock, composed wholly of corroded quartz phenocrysts in a perfectly glassy ground-mass. This same rhyolite caps the formation along the ridge on the east side of section 1, T. 47 N., R. 15 E. Here, too, is found a much fractured obsidian. It is dark colored, and at a distance somewhat resembles a granite. At close range it looks like a coarse-grained sandstone, the particles of which are angular and glassy.

There are two distinct occurrences of ore in this district; the quartz veins in the basalt and andesite, and replacement deposits in the dacite. The quartz veins in the basalt and andesite are 'gash' veins. These strike nearly east and west, and none of them is persistent in either dip or strike. In width they vary from a thread to 2 ft., with an average of about 12 in. In assay value they are just as erratic. The quartz is coarse-grained and vitreous. Some crystals 10 in. long and 1½ in. thick have been found.

The ore occurrences in the dacite are decidedly different. They are, with one exception, replacement deposits along zones of shearing. The replacing material is gold and silver-bearing quartz. It is not unusual to find a hand-specimen in which all gradations from unaltered dacite to secondary quartz can be seen. These deposits are banded to some extent, and the width of the zone in which replacement has occurred may reach 20 ft. in places. This will not all be quartz, but will consist of fragments of dacite partly altered to quartz, and thoroughly consolidated by silica into one mass. This character of ore resembles a breccia. Accompanying this, in the pay-shoots, is a vein of quartz. This will vary in width



Outcrop of Oregon Vein in Basalt.

from a few inches to 2 ft. It is the presence of this quartz that determines the pay-shoot. These zones are persistent in strike and depth, as far as developed. The Sugar Pine vein can be traced for 2000 ft., and one other, the Big Four, for an equal distance. The former strikes almost east and west, and dips between 60 and 70° to the south. The latter strikes N.45°W., and dips 65 to 75° to the northeast. The quartz is fine-grained and a little yellow in color. The exposed faces resemble the surfaces of lime accretions on rocks.

There is on the Big Four a quartz vein filling a well defined fissure. This fissure strikes N.40°W. and dips steeply to the northeast. It is very persistent in strike, outcropping for over 1000 ft. The quartz is fine-grained, of 'sugary' texture, and is separated from the walls by a small selvage. The quartz varies in width from a few inches to 4½ ft., and seems to follow the line of a former dike. This dike is a dense blue, thoroughly silicified rock, carrying variable amounts of pyrite. In some places the quartz is on one side, at others in the middle, and elsewhere on the other side of the dike. The dike and quartz average 6 ft. in width.

In the extreme northwest corner of the district, in a region of mineral springs, are some veins of chalcedonic quartz. As yet they show no promise of being economically important.

The ore is a clean silicious one, and gold and silver are the only elements of economic value which it contains. Those ores from the andesite and basalt areas yield sparingly chalcopyrite and carbonates of copper. The ores from the dacite area, with one exception, hold the metals as free-milling gold and silver. Ore from a vein on the school section (Sec. 36, T. 48 N., R. 15 E.) has little or no free gold, but considerable in combination with sulphides. The best ore in the district, from the Sunshine vein, yields native silver as well as gold. The ratio of the gold to the silver content in the ore is 1 to 1.5. The rich ore from the Sunshine is an exception to this, giving 1 of gold to 6.5 of silver. The ore from the basalt and andesite veins will average $10 in gold, and from 0.5 to 2 oz. silver per ton. An exception to this is the ore from the Mountain View, which averages $25 per ton. There are some rich streaks in these veins, but their total volume is small. One seam on the Mountain View assays $6000 per ton. There has not been sufficient systematic work done in this part of the district to determine the dimensions and trend of the ore-shoots.

The orebodies in the dacite shear-zones have not been sufficiently developed as yet to definitely determine their trend, or the causes which have produced the present concentrations, further than that the shoots pitch at a low angle to the east. One shoot on the Sugar Pine is at least 150 ft. long, with an average width as developed of 5 ft. Sixty feet west of this shoot the west drift had just entered another. In these shoots the gold and silver content gradually increases on entering from the east, and it drops suddenly as the west edge is approached. The ore from the shear-zones varies from $7.50 to $30 per ton, depending upon how cleanly it is broken. For some distance from the ore, the dacite assays from 40c. to $1.50 gold per ton. The quartz vein on the Big Four has a well defined pay-shoot, pitching 45° to the southeast, over 300 ft. long. The ore in this shoot varies in width from 6 in. to 4½ ft., and in value from $7.50 to $65 per ton, with an average value of $18.50 per ton for 18 in. width. This is a persistent vein, and its development is fulfilling its surface promise.

The Sunshine vein is small and rich, following a shear-zone. The surface in its vicinity was covered with 'float', 10 tons of which were collected and milled, yielding $75 per ton. The vein is only about 10 in. wide, but contains ore which averages higher than $100 per ton. The float from this vein can be picked up for a distance of 1200 ft. along the strike. This will probably develop into a valuable small property.

The elevation of the camp, 6000 to 8500 ft. above sea-level, makes the winters long and severe. The snow comes about November 15, and is on the ground until July 1. Poor roads, as yet but little traveled, intensify the discomforts of the winter. The contour of the district is of such a character that, for some time, no deep mining need be done by anything but tunnels. Adits 3000 to 5000 ft. long will develop from 1000 to 1500 ft. of backs, with a corresponding proportion of backs from shorter ones. There is, on most of the locations, an abundance of timber, such as fir, pine, and spruce, of sufficient quality for all mining purposes. Water in sufficient quantity for all domestic, steam, or milling needs springs from the district, but water for power-purposes cannot be obtained short of 25 miles from Deep creek, Oregon.

Up to the present time there have been no milling facilities in or near the district. This has held back development materially, as with the present system of transportation, and the distances to be transported, nothing short of $50 ore can be worked profitably. However, a custom mill is now being built, which is half completed. It will be ready to accept ores for treatment next spring. In this mill the ore will pass from a Blake breaker to a Lane Chilean mill. The pulp, after passing a 100-mesh screen, will flow over silver-plated plates to a classifier, from which the sand will go to vats for cyanidation, and the slime to slime-tanks. The gold is fine and therefore fine grinding is necessary.

The Innoko is a tributary of the lower Yukon near the Kuskokwim, which is next to the Yukon among Alaska rivers. Many placers occur on small streams in areas that are drained into the lower Yukon or the lower Kuskokwim, and their occurrence is interesting to the miner because it proves that the formations of the upper Yukon gold-belts extend much farther southwest than has generally been supposed and that they are gold bearing at many scattered localities throughout their extent.

Batan coal mines are now turning out 6000 tons per month, and the demand for the product already exceeds the supply. The Manila Electric Railroad & Light Co. has placed an order for a continued supply of this coal for its plant in Manila.

Whitepine Iron-Ore Deposits.

By E. C. Harder.

*The Whitepine district lies on the west slope of the Sawatch range about ten miles north of Marshall Pass, in the southeastern part of Gunnison county, Colorado. The principal deposits lie on the east slope of the valley of Little Tomichi creek, about half a mile northeast of Whitepine, at an elevation of about 9500 feet.

The ore-bearing area has a northwest-southeast trend lying along the contact of a granite with shale and limestone. The granite, which is on the northeast and occupies the upper part of the slope, is directly connected with the great pre-Cambrian granite mass forming the Sawatch range. The sediments are presumably Paleozoic, being lithologically similar to those of the Taylor Peak district. Next to the granite there is generally a layer of vitreous quartzite, of varying thickness up to 30 ft., which may represent the Cambrian. The iron ores occur locally between this quartzite and the overlying rocks. Outside of the quartzite and ores, where these are present, there is a strip of dark-colored limestone and shale, chiefly the latter, and outside of this is a blue or white crystalline limestone, which occupies the lower and principal part of the slope. This limestone is similar to the Carboniferous limestone of Taylor peak. Besides these rocks a light-gray rhyolite is present as an intrusive into the dark shale formation and along the granite contact. The rhyolite has been intruded in disconnected masses, whose forms could not be determined from the exposures found. The rocks are much fractured and faulted, but the details have not been worked out.

The iron-ore deposits of this district are of two kinds—limonitic bog ores and replacement deposits of magnetite and limonite ores. The former occur in a small deposit along Little Tomichi creek within the granite area, about a mile above the principal deposits. The latter are found in small irregular masses in the limestone-shale formation near the granite contact. In some places only a few feet of vitreous quartzite intervene between ore and granite; in others a mass of rhyolite and layers of the dark limestone-shale formation are present in addition to the quartzite. No place is known where the iron is immediately in contact with the granite. In the Iron King cut, the largest deposit in the district, no quartzite is exposed between ore and granite, but the direct contact cannot be seen. As a rule the dip of the contact is steeply toward the iron.

Detailed Map of the Whitepine Iron-Ore Deposits.

The principal deposits vary in thickness from 5 to 40 ft., and extend along the contact for a distance of several hundred yards. Beyond in either direction is merely a local staining and a few small veins. Ore occurs also in small bodies where the rhyolite has intruded the sediments away from the granite contact, especially where the sediments are limestone, and a few deposits are found in the limestone away from the intrusive masses. The deposits along the granite contact and in association with the rhyolite consist largely of magnetite, but those entirely within the limestone, at some distance from the igneous rocks, are composed of dark brown porous limonite.

The ore associated with the igneous rocks is mainly a glossy, black, compact magnetite with seams and specks of limonite. Locally this ore grades into blue fine-grained magnetite with chlorite, quartz, and

*Abstract from 'Contributions to Economic Geology, 1908', U. S. Geol. Surv., Bull. 380.

calcite disseminated through it, similar to some of the Taylor Peak ore. In the Iron King cut masses of serpentine and quartzite are interleaved with the magnetite. Large masses of brown ocherous material, which probably represent incomplete replacements of the limestone-shale formation, occur between the sediments and the orebodies. This partly replaced border varies in thickness and degree of alteration; in some places it consists merely of stained quartzite, but elsewhere it is soft and friable and contains numerous veins of magnetite, limonite, chlorite, and kaolin. Here and there masses of partly replaced sandstone and shale occur as lenses surrounded by ore or as bands between adjacent ore deposits. The sediments near the ore deposits are heavily impregnated with contact minerals, among which the most conspicuous are epidote, chlorite, amphibole, pyroxene, garnet, pyrite, and magnetite.

From the foregoing statements it is clear that the iron ores are replacements of the calcareous parts of the limestone-shale formation. The nature of the gangue minerals shows the solutions to have had a deep seated source, but the distribution of the deposits does not show as clearly as the Taylor Peak deposits the nature of this source. The fact that the deposits lie along the granite contact seems to point to the granite as the source, yet that rock is presumably much older than the overlying rocks that contain the ores. The association of the intrusive rhyolite with the granite contact and hence with the ores appears more significant. It is probable that the rhyolite intruded at this horizon, because it was easier of access, on account of the fracturing, and that the ore-bearing solutions were associated with it. Direct evidence for this hypothesis is not everywhere plain, yet the orebodies and the rhyolite are closely associated and the sediments become altered and iron stained as the intrusive rock is approached. The limonite ore within the limestone occurs as veins, breccia deposits, and small irregular replacement masses and is clearly of a different type from the contact ores. It was probably deposited by iron-bearing meteoric waters along open channels and replaced the adjoining rocks. The deposits are of small size and of no importance, few of them being more than 15 or 20 ft. in diameter.

The bog-ore deposit occurs in the valley bottom along Little Tomichi creek, about 1½ miles northeast of Whitepine. The granite contact crosses the creek between it and the contact deposits, and the bog ore is a considerable distance within the granite area. The deposit is 3 or 4 ft. thick and perhaps 2 or 3 rods square and consists of successive layers of ore several inches in thickness. The ore is light and porous and is made up largely of evergreen needles and other vegetation, replaced by limonite. At several places along Little Tomichi creek, between this deposit and Whitepine, where the valley bottom is boggy, bog ore is being formed at the present time. This process is especially noticeable below the slope where the contact deposits occur.

So far as present developments show the Whitepine deposits can be considered of but small economic value. They occur in a narrow contact zone, and are probably too thin to make mining profitable.

Aroroy District, Masbate.

*During the past two years miners of the Aroroy district, Masbate, Philippine Islands, have been steadily engaged in legitimate development, with the result that they have succeeded in pulling the mining industry of this district out of the mire into which it was plunged by the reckless operations of some of the earlier companies. H. G. Ferguson, geologist of the Division of Mines, has been in the district almost continuously since last August, collecting material for a bulletin on the geology of the area. The following details of the mining operations are presented in advance of the publication of the report.

Geologically, the district is composed of a series of old sediments which have been intruded by a mass of quartz diorite. Later a large amount of volcanic action has taken place, giving the series of andesites and breccias which today cover most of the district and contain all the more important veins. Vein formation took place in Tertiary times. The principal veins of the district occupy the three large hills, Mounts Aroroy, elevation 255 metres; Bagadilla, 350 metres; and Kalakbao, 205 metres. As a rule, the veins are broad, straight, and well defined. Widths of over 20 ft. are not uncommon, and faults are rare. The ore commonly occurs as banded honeycombed quartz filled with manganese or iron oxide, the banding being most pronounced near the walls. Varying amounts of calcite also occur in several of the veins. In many veins there is evidence of different periods of mineralization. The walls are nearly always well marked and the ore breaks cleanly from the country rock. In some cases the country rock, a decomposed andesite locally called porphyry, shows workable ore for several feet from the vein proper. So far exploration has been carried on only in the oxidized zone, which extends to great depth, reaching nearly to the permanent water-level. At this depth the ores show a tendency to change to a massive blue quartz, impregnated with pyrite. The strong relief of the district places a large amount of the available ore above the water-level, and consequently it is in the easily worked oxidized form. Tests which have been made in the United States for different companies have given from 20 to 33% extraction by amalgamation. It is probable that actual practice might even give less; this low amalgamation being probably due to the large amount of manganese in the ore. On the other hand, the ore is particularly adapted to cyanidation, tests made in the United States and by the Bureau of Science at Manila showing that an exceptionally large recovery can be obtained by this method. One company which is now preparing to erect a modern mill and cyanide plant, plans to dispense with plates entirely, the stamps crushing in the weak cyanide solution. Suggestions have been made at different times that Chilean mills might be used on account of their cheapness, but the large amount of hard massive quartz which must be handled would probably make this method impracticable.

*Abstract published by courtesy of Warren D. Smith, Chief, Division of Mines, Manila.

The question of power is one of the most serious in the district. The Guinobatan river runs nearly dry at times, and it is doubtful if even with a dam and storage reservoir it could be regarded as a source of power. Good water-power might be developed by a dam at the upper gorge of the Lanang river, which has a greater and more constant volume than the Guinobatan. At present, mangrove firewood can be delivered at the mines at an average cost of about ₱5 per cord, a cord being considered approximately equivalent to one-half ton of Australian coal. If several power-plants were working, however, the more accessible parts of the mangrove area would soon be cut away and the price would increase. The enforcement of the local Forestry Bureau regulations in regard to the cutting of the large trees only, would also tend to increase the price. On the other hand, there is every probability that a sufficient supply of Philippine coal will soon be available at a reasonable price. Coal from the Batan mines, which at present have a monopoly of Philippine coal mining, sells at the mine for ₱6.50 per ton, and could be brought to Aroroy. Besides this, coal of better quality has been recently found on the island of Masbate, about forty miles down the coast from Aroroy. It is hoped that a company will soon be formed to prospect these deposits. If satisfactory results are obtained, the mines at Aroroy should be able to secure their coal at a much better figure. The islands of Cebú and Mindoro also contain coal, and no apprehension need be felt in regard to fuel.

In regard to timber, the district is most favored. Molave and other timbers of the 'first group' sufficient to satisfy all immediate requirements are to be found on most of the claims, particularly those of the Colorado, Syndicate, Tengo, and Aroroy companies. At present, the following represent the average prices paid for timbers: first group timber, 7 ft. long, squared 7 in. (in some cases only molave accepted), ₱1; same wood, rough, 75cv.; lagging (molave boards or other first group wood), per running foot, 2cv.; ties, 4 ft. by 8 in. by 4 in., each, 10 to 12 centavos.

The following timbers are commonly used in the district, listed in the order of their preference: (1) Woods suitable for permanent workings: molave, dungan, kobe, bansalangan, matamata colorada, matamata blanca. (2) Woods available for temporary timbering, as in stopes which will eventually be filled: lauan, mangasinoro, to-og. Prices will increase somewhat as the timber in the immediate vicinity of the mines is cut, but the whole central range of the island is heavily wooded and there need be no fear of a shortage of timber.

As elsewhere in the Philippines, the labor supply is not entirely satisfactory, though up to the present time there has been no difficulty in securing the necessary labor at 60cv. per day if food is provided, or 80cv. if the laborers board themselves; and a number of fairly efficient miners have been trained. Wherever possible, work is let by contract, as this has been found to secure better results, owing to the close supervision necessary where native labor is paid by the day. There may be a temporary shortage of labor in the district when mines begin operations on a large scale; but there would probably be little difficulty in getting laborers from neighboring islands if necessary, in which event Government assistance can be counted on. The native is an irregular laborer, and it would always be necessary to have available a larger force than actually needed. It might not be possible to work a full force on Sundays and fiestas, but enough steady men could always be secured to keep a mill running continuously, even if mining work was occasionally broken into.

As stated before, the district is exceptionally situated for cheap mining. The mines are from a mile and a half to three miles distant from an excellent harbor, and this, together with the nearness to Manila, should be an important item when it comes to getting in heavy machinery. The high relief of the country gives excellent opportunity for attack by adit, and a large proportion of the best ore can be so won. While no definite figures are available, Mr. Ferguson believes that in a properly managed company the total costs of mining and treatment should not exceed ₱6 per ton. Allowing 20% for loss in treatment, this would give a profit of ₱2 per ton on ₱10 ore, and the great mass of available ore runs higher than this. The following figures, based on data which he has collected in the district, give average costs of prospecting and development work: drifts, ₱4 to ₱6 per foot; raises, ₱4 to ₱8; shafts, ₱12 to ₱30.

The Keystone Mining Co., operating on Aroroy mountain, the Colorado Mining Co., on Mount Bagadilla, the Syndicate Mining Co., operating the claims of the Eastern Mining Co. on Mount Kalakbao, and the Tengo Mining & Development Co., working the claims of the former Mount Cogran Mining Co. on Mount Cogran, have all been engaged in vigorous development during the year. Besides these, the Aroroy Mining Co. has lately taken over four groups of claims on Mounts Bagadilla and Kalakbao, including the former Gold Bug property, all formerly belonging to Messrs. Edelmaier and Beasley, and prospecting is being carried on vigorously and intelligently. In all cases the development now going on is the result of careful planning and is being well done. As a consequence, large quantities of ore are being blocked, and when production begins again it should show a constant increase from year to year. Other operators in the district who have continued steady work are Messrs. Hayes, Draper, and Schwab. Placer mining in the district has not recovered from the damage done by the hurricane of a year ago, when the dredge of the Lanang Dredging Co. was wrecked and their camp destroyed. The placer grounds of this company are now being re-tested and it is possible that the dredge will be re-built. In conclusion, it may be said that the condition of the district was never better, and it is Mr. Ferguson's opinion that while Aroroy may never rank with the great mining districts of the United States or Australia, the next three or four years should show several large and profitable mines.

Natural gas is being developed in Carelmapu, southern Chile, in proximity to deposits of iron and copper.

Zinc Oxide Manufacture.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM F. GORDON.

The manufacture of zinc oxide on a commercial scale in the United States commenced in 1855 under patents issued to Samuel Wetherill and Samuel T. Jones. The Wetherill patents cover the type of furnace and the preparation of the material, and the Jones patent the manner of collecting the fume. The Wetherill furnace consists of an arched chamber of rectangular horizontal section. The hearth is composed of perforated cast iron grate-bars, the whole forming a closed chamber resembling the ash-pit of a boiler. It is supplied with air under pressure. The arched roof of the furnace is pierced with an opening connecting with the clarifying and collecting apparatus. The furnace is operated by spreading over the grates a layer of fine coal or coke, and above this in another layer, the mixed fuel and ore. An average charge consists of about 30 lb. of fuel and ore to each square foot of hearth. The air under pressure coming through the perforated grate bars, upon which the charge rests, oxidizes the lowest coal to carbonic acid, which passing through the bed of coal is reduced to carbon monoxide. The monoxide reduces the zinc oxide of the ore to metallic zinc, being reoxidized in the process of carbonic acid. The zinc, at the high temperature of the furnace, volatilizes and its heated vapors, uniting with the oxygen of the carbonic acid, are again oxidized. This reduction and oxidation of the zinc taking place in the same furnace chamber is one of the interesting features of the process. The oxidation must take place from the carbonic acid, as the nature of the process prohibits sufficient atmospheric oxygen.

The residue or slag is removed from the furnace after the charge is treated and consists of ash and the non-volatile matters of the ore. It is entirely scoriacious in character. If the ore contains gold, silver, or copper, these are found in the slag and retreated by ordinary smelting. The oxide formed is carried by exhaust fans through the clarifying and cooling systems, and is finally collected in large muslin bags. A great number of these bags are connected to the sheet iron conveying pipes, permitting the entry of the gases in which is suspended the amorphous zinc oxide. The gases escape through the porous cloth and the zinc oxide is strained out. The bags are shaken at intervals, the oxide falling and being collected in proper receptacles. This, in brief, is the zinc oxide process.

Some years later E. O. Bartlett attempted the manufacture of basic lead sulphate from galena, using in part the zinc oxide method, modified to suit the new conditions. Basic lead sulphate, when properly made by sublimation, shows characteristics which make it the equal, if not superior, of carbonate of lead (the white lead of commerce), for paint purposes. It is not nearly so poisonous. It possesses great stability under atmospheric conditions, neither oxidizing and chalking off as does white lead, nor turning black in presence of sulphur compounds generated by burning coal. After much trial and experiment the results justified Mr. Bartlett's faith, and now great quantities are manufactured by the Picher Lead Co., at Joplin, Missouri. This pigment, as now made, is the peer of any on the market.

The process is as follows: The furnace used is a modification of the Scotch hearth. The mixture of ore and coke is supplied with a heated blast and the lead volatilizes in the form of a mixture of oxide, sulphate, and sulphide. The first product is a blue-black powder and contains an excess of sulphur. This blue powder is collected in a bag-room like zinc oxide. It is next placed on a floor and ignited, there being enough sulphur to burn without the addition of other fuel. This burning reduces the sulphur to proper quantity. The ignited blue powder, together with tin-scrap and coke, is charged into a furnace of cupola type, and is again volatilized, this fume or powder being collected in a second bag-room similar to the first. The fume is a white, impalpable powder, and is packed and sold as sublimed white lead. It is a basic sulphate of lead or a mixture of sulphate and oxide.

When I was managing the zinc oxide works at Joplin, Missouri, I found it possible to build a plant which would use the complex zinc-lead ores of the West, and at one process produce zinc oxide and basic lead sulphate. From a chemical point of view it looked unreasonable, but trial showed that a plant properly built would produce the results. Such works was built at Coffeyville, Kansas, and its success was very marked. This plant is owned by Sherwin-Williams company, which manufactures the pigment for use in paints.

This process is bringing into use the very complex zinc-lead ores and permitting their treatment without separation. The pigment produced is a compound of zinc oxide and basic lead sulphate and is second to none for quality and color. Ores which contain zinc and lead, and also copper, silver, and gold, are successfully treated. The non-volatile metals remain in the slag and are treated for these metals by ordinary methods.

That tungsten is used in making armor plate has been stated, and there has been a general belief that most of the tungsten mined was so used. It is stated, however, by the Ordnance Bureau of the Navy Department that tungsten is not now and, so far as known to that bureau, never has been used in the manufacture of armor plate in this country, and it is not known to have been so used in other countries, though it has probably been used in experimental armor plates. One of the most essential properties of armor plate is its ability to resist shock, and this property is not imparted to steel by tungsten. As the melting point of tungsten is very high—about 3080°C.—the metal is valuable for use as a filament in incandescent electric lamps, and such lamps are rapidly coming into common use. The whiteness of the light given by the tungsten filament makes it much superior to that of carbon, and the efficiency of the tungsten lamp is more than twice as great as that of the carbon lamp. Thousands of filaments can be made from a pound of tungsten.

Stoping Methods at Kalgoorlie.

By J. Cheffirs.

*In dealing with this subject it is not my intention to write a detailed description of the various methods in vogue in the Kalgoorlie field, but rather to give a brief outline of three which are most universally used, and to make a few comparisons. The three methods are known as 'the Rill', 'the Flatback', and 'the Shrinkage'. For comparative purposes each method will be applied to a block of ore 500 ft. in length, and opened up by levels 200 ft. apart. It is necessary in 'the Rill' system, in order to facilitate handling the waste, to make connections between levels by raises and winzes about every 100 or 150 ft. along the orebody. After the leading stope is open for the full length of the drive, the level is timbered. Single stulls are put in up to a width of 14 ft. If the span is too great for stulls, set timbers or saddleback stulls are used. Stulls are lagged over with 4-in. gimlet poles, and wooden chutes are built at intervals of 50 ft. Ore passes are cribbed up through the filling directly above each chute, and are constructed of 7-in. round timber or 3 by 9 square timber, the passes measuring 4 by 4 ft. in the clear. Occasionally a double pass may be carried up, one side serving as a traveling way. Stoping is commenced off the winzes, and rills are gradually formed, one on either end of each winze. The rills are generally at an angle of 37° off the horizontal, this allowing for the boring of all water-holes. After the rill is cut through, and the ore, which gravitates down the rill to the ore pass, is cleaned up, machines are transferred to another portion of the stope, ore passes built up, and filling proceeds. The filling, which usually consists of residues, is dumped down the winzes from the level above and gravitates down the rill into position, although at the extreme points of rills a certain amount of handling is required.

The flatback system is similar to the rill, the difference being that the stope is carried horizontally. As the ore does not gravitate, but lies where it is broken, it is necessary to have ore passes at shorter intervals. Filling is also more expensive on account of the extra handling required. This method is usually used where the ground is heavy, and bulk heads are required to keep up the back or walls, as the flat bed of broken ore and rock forms a solid foundation.

In the shrinkage or lay system one connection between levels at about the centre of the block is all that is needed. The level is timbered as in the rill system, except that the chutes, which are put in every 20 ft., are constructed of ⅜-in. steel. These chutes practically consist of a steel lip protruding into the level, the bottom of the chute being formed by the broken ore itself. Any rocks which are too large to pass through the opening can be blasted without damaging the chute. The stope is rilled at an angle of 23°, all water-holes being bored. Sufficient of the broken ore, approximately 44%, is drawn off to allow comfortable working room between the back of the stope and the top of the broken ore, which acts as filling until the stope is completed. Two ladderways are cribbed up through the ore, one near either end of stope, built of 6-in. half joggled logs, and measuring 3 by 3 ft. in the clear. These manways are commenced between two chutes, so that the shrinkage of the ore directly over the chute will not affect them. When blasting, only a few holes are fired in a round, so as to allow the large rocks to be broken down sufficiently small to pass through the chutes. After the stope is broken through to level above, all ladders and air pipes are removed and the balance of the ore remaining in the stope is drawn off. The passes then collapse, and the timbers are regained through the chutes, to be utilized in other places. Filling is then a simple matter, as, the stope being open, the broken ore may be dumped at whatever point required.

Where conditions permit of the satisfactory working of the shrinkage system I prefer it. In the rill system, in opening up the block of ore, three or four winzes are essential to economical mining, while in the shrinkage system one winze is sufficient. A considerable saving in the cost of development is thus effected. Expensive ore passes, which have to be installed and maintained in the rill system, are entirely dispensed with in the shrinkage system. Loss of time, in shifting machines preparatory to filling, is avoided, because in the shrinkage system the stope is not filled until after it is broken through and the ore drawn off. In the rill system a certain percentage of ore, no matter what care is exercised in cleaning up rills, is lost in the filling; while in the shrinkage system a certain amount of low-grade material scales off the walls and reduces the grade slightly. This can be reduced to a minimum by strict supervision in the breaking of the stope. There are certain conditions under which the shrinkage system, if applied, would be unsuccessful, such as in flat veins or in stopes where the walls and backs are bad; but where the lode is at all near vertical and the walls fairly good I am satisfied that it is a cheaper and just as satisfactory as the rill system. In isolated patches of ore, which probably would not be worth considering if a lot of dead work were necessary to deliver the ore in the stope, this system can be used to advantage.

*Abstract from Trans. Aust. Inst. Min. Eng., Vol. XIII.

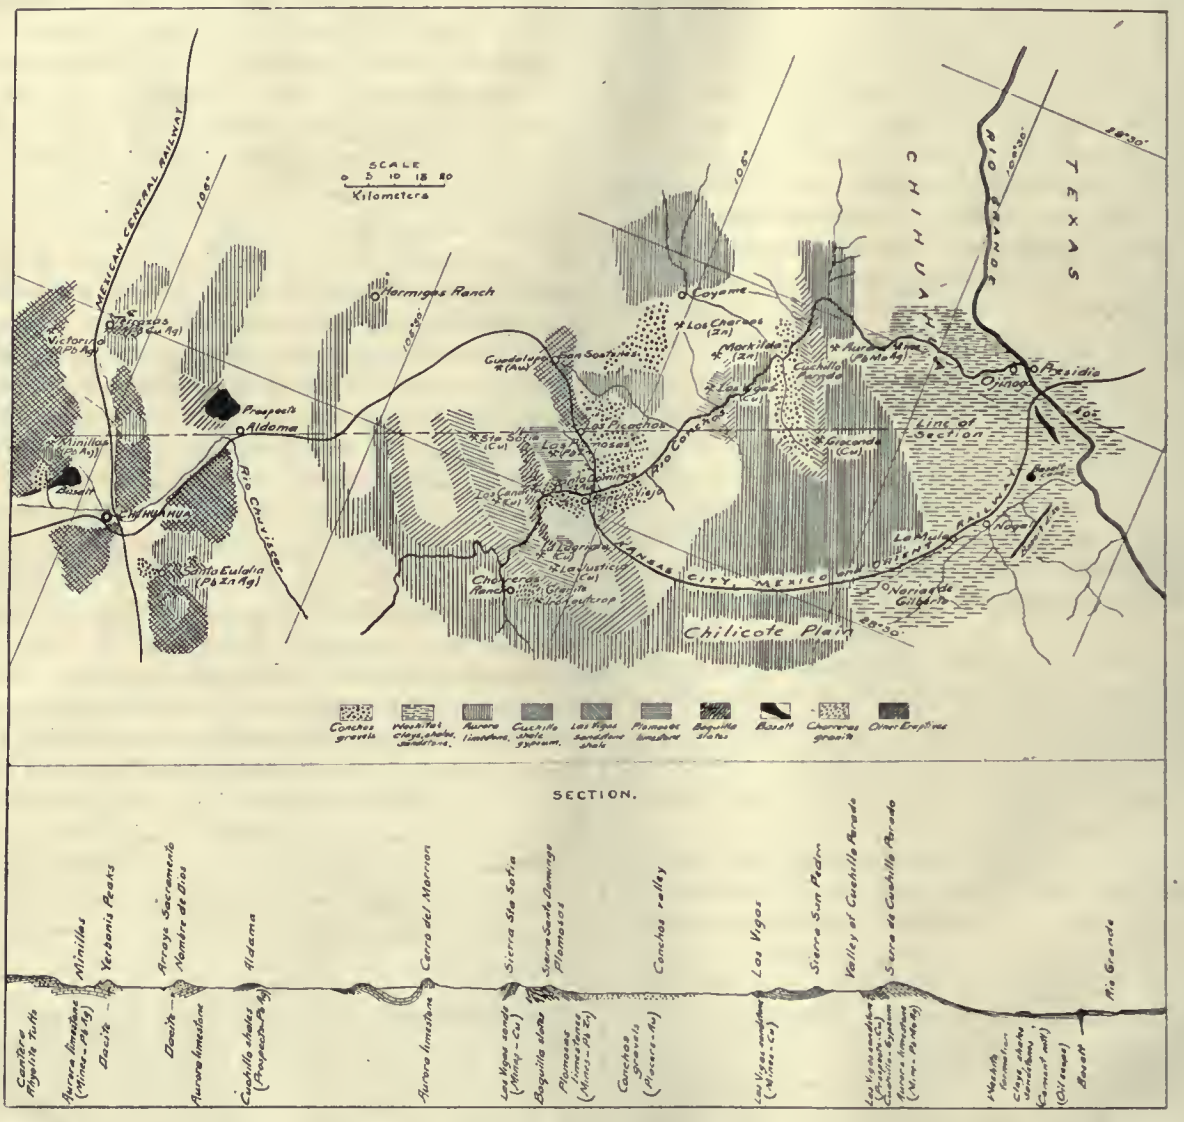
The Illinois runs from petroleum wells showed an increase during January as compared with the month previous, but there was also a substantial increase in the deliveries, so that the net results represented a reduction in the stocks. The January runs from wells in Illinois as credited to the Standard, or Ohio Oil Co., were 2,226,107 bbl., as compared with 2,130,736 in December. The regular deliveries for January were 1,226,378 bbl.; the other deliveries were 1,184,565 bbl., as compared with 1,382,412 during the previous month. The gross stocks of Illinois oil held by the Ohio Oil Co. at the close of December were given at 28,671,543 bbl.; and at the close of January 28,455,129, a reduction of the stocks in January amounting to 216,414 barrels.

The Utah Copper Co. has reported to the New York Stock Exchange for the year 1909 a production of 51,749,233 lb. fine copper, with the average price received, 12.96c. per pound, and net profits, $2,159,786.

Prospecting in Chihuahua.

Written for the MINING AND SCIENTIFIC PRESS
By R. H. BURROWS.

Among the less explored regions of Mexico, that least known is the eastern part of Chihuahua, and northern portion of Coahuila, lying north of the 27th parallel of latitude, bounded on the west by the line of the Mexican Central railway, and on the east by the National railway and the Rio Grande. The lack of knowledge regarding this part of the Republic is due to its want of water. The rainfall is slight and the springs are few and far between. is not lacking, the chief supply being mesquite, that most useful of desert shrubs, which during the period of its fruiting in June and July is also capable of affording food for man and beast. It is said that the aborigines always became fat at this period, subsisting entirely on the sweet succulent pods. These are still made use of by the Mexicans who grind the bean together with the pod into a paste called *mesquitamal*, which is both palatable and nutritious. Travel is comparatively easy so far as topographic features are concerned, and a great deal of the country may be covered by wagon. The country in general is similar to that seen along the Mexican Central railway from Jimenez northward



Due to these conditions this country constituted the last stronghold of the Comanche Indians in Mexico, from which they were with much difficulty dislodged by the combined forces of the Mexican and United States governments. In some instances, the springs are so hard to find and so far apart that no small risk is incurred in traveling without a guide.

Although water is scarce, grass is everywhere plentiful, besides a large variety of thorny shrubs peculiar to arid localities. Timber worthy of the name is exceedingly scarce; cottonwoods grow in the vicinity of springs and along the few watercourses. A sparse growth of pine and oak crowns the higher summits that border the Rio Grande, as in the Sierra Rica. Wood for camp-fires, however, to the border, and is contemporaneous in formation, constituting part of the same geological province, and about equally divided between mountain and plain. The mountains prevail as small topographic units, consisting of narrow ranges from five to ten miles in length, encompassed on all sides by plains, the mountains rising from five hundred to two thousand feet above their flat surroundings. On approaching the Rio Grande, the plains merge into a continuous range of rugged hills and mountains which follow the river almost without a break, along the northeast border of the States of Chihuahua and Coahuila. The axes of the range have a general northwest to southeast direction, this uniformity having been determined by the folding and faulting

which accompanied the elevation of the continent to its present position. The ranges show the upturned edges of the strata in a succession of exposures of the same geological formations, until the eastern border is approached, where later beds are encountered. The prevailing rocks are limestones and sandstones of sedimentary origin, probably corresponding to the Comanche Series of the Cretaceous. Sparsely distributed throughout are small areas of volcanic tuffs and massive eruptives.

The importance of this region with reference to mining, and the inducement it offers to prospectors, may be better appreciated by calling attention to the mining districts of Santa Eulalia, Naica, Sierra Mojada, Sierra Almoloya, and others within the same zone and situated in small ranges which exhibit the same topographic and geologic characteristics as those farther in the interior. Wherever established routes have made this field accessible important mines have invariably been discovered. The country in question is divided into two parts by the Conchos river, the settlements along the river-bottom having resulted in the prospecting of a strip 100 miles long by about 20 wide. Within this strip is the gold district of Guadalupe; the gold placers of Santo Domingo; the lead and zinc mines of Plomosas, Coyame, and Cuchillo Parado; the copper mines of Chorreras and Las Vigas; while across the Rio Grande a short distance from the mouth of the Conchos, is situated the Chanate range, where the Shafter district produces about half a million ounces of silver annually. Above Presidio del Norte, on the Mexican side, recent important discoveries of silver have been made; while below Presidio is the Terlingua quicksilver district. On the western border of the region, reached by the old stage routes, are situated Sierra Mojada, Naica, Santa Eulalia, and Terrazas. Mention should also be made of the recently discovered district of the Sierra de los Lamentos. The existence of such a number of important mining districts around the edges of this field surely justifies more attention to the interior than it has yet received. The accompanying map shows approximately the geology along the line of the Kansas City, Mexico & Orient railway, between the city of Chihuahua and the Rio Grande, and may be accepted as generally typical of the country under consideration. The principal ore-bearing formations are the Plomosas limestone, the Las Vigas sandstone, and the Aurora limestone. The latter is the same formation in which the ores of Sierra Mojada, Almoloya, Santa Eulalia, and other great silver-lead-zinc deposits of central Chihuahua are found. The Aurora lead mine and the Shafter silver mine are also within this formation. Below the Aurora limestone, and separated from it by a considerable thickness of gypseous shales and thin-bedded limestones (Cuchillo formation), are the copper sandstones of Las Vigas. In these rocks are found the mines of Las Vigas, Justicia, Santa Sofia, and others, which have produced and are still producing a goodly quantity of copper ore. These mines are not confined to one locality, but are situated on sandstone outcrops fully 30 miles apart. I have had occasion to travel many miles over these outcrops, and wherever the bedrock permitted examination of the bedding-planes some copper sign could always be distinguished. This would seldom be more than a mere stain of green carbonate; but when followed it generally led to some workable deposit, as in the mines above mentioned. The character of ore in these sandstones is high-grade, consisting of fairly pure oxides, glance, and chalcopyrite, and carries as a rule from 4 to 10 oz. silver per ton. The Plomosas limestone yields copper, lead, and zinc, the latter being the principal product, consisting of carbonate which averages 50% metal.*

These three mineral-bearing formations underlie the entire region here considered, where they are exposed at frequent intervals in the scores of small ranges which constitute its principal topographical feature. Every one of these ranges merits attention from the prospector's standpoint, and offer better chances for the discovery of important mines than any part of the Republic that I am familiar with. Prospecting this field involves no greater difficulties than those encountered a few years ago in the desert portions of Nevada and Utah. The climate is somewhat similar, the midday heat being quite high, but generally tempered by a breeze, while the nights are always cool and comfortable. During the winter the plains are subject to cold winds, but it seldom snows. From September to May is the most favorable season for prospecting. The country cannot be recommended to the type of prospector who takes his pick, frying pan, and sack of grub on his back, trudging off on foot; but it does hold out exceptional inducements to energetic men who can afford an outfit of mules, or better still, a wagon, using the draft animals for riding and packing when necessary. In this way, and making a permanent camp at some spring as a centre, the country within a radius of 20 miles could be covered. At the farthest camp that could be made in the interior, the prospector would not be removed more than about four days from some base of supplies. Preparatory to the actual work, a couple of weeks might be spent profitably in an inspection of the mines tributary to the Conchos river, making himself familiar with the mode of ore-occurrence, and the relations of the enclosing rocks.

It must not be understood that the region spoken of is unknown to the natives. Their long acquaintance with the country and knowledge of the sources of water-supply enables them to travel across it in almost any direction, and there is generally some native settler, or at least a cattle camp in the vicinity of the principal springs. Consequently intelligent guides are not difficult to obtain.

The neglect of this district by prospectors may be explained on the assumption that the Sierra Madre and southern parts of the Republic, with their pleasant climate, abundance of timber and water, and the convenience of food supply, have diverted attention from this other promising field, in the same way that the Rocky Mountains and Sierra Nevada were thoroughly gone over before much serious attention was given to the arid region lying between them.

*For further details regarding the geology and mineral resources of this region, see article on 'Geology of Northern Mexico', by R. H. Burrows, in MINING AND SCIENTIFIC PRESS, August 28 and September 4, 1909.

Methods of Electrochemical Amalgamation.

By Elmer Ellsworth Carey.

*While the theory of electrochemical action has been known for many decades, it is only within the last few years that methods and machines for making a practical use of the theoretical knowledge have been devised. In 1859 United States letters patent were issued to Henry Brevoort, of San Francisco (No. 25,242), for an arrastre in which amalgamation was intensified by electrochemical means, and in 1862 a patent (34,881) was issued to J. C. Davis for an arrastre in which means were provided for galvanic action. On July 2, 1861, Frank Dibbern secured a patent on a barrel amalgamator in which he provided for 'local electrochemical action' by adding zinc or iron filings and a mercury salt to the water and pulp. His idea was that local galvanic couples would result, the mercury being deposited on the gold particles (cathodes) by electro-deposition. In 1867 Julio H. Rae was granted a patent for an electro-cyanidation process, which covers the essential points of the systems of today. In 1882 Breakell and Haycraft used an electrolytic cyanidation process in South Australia; in the United States patents for similar processes have been issued as follows: 290,295; 491,686; 684,672; 641,808; 364,372; 779,365; 863,934; 504,678; 668,283; 370,366; 363,411. These patents refer to devices in which the pulp is agitated in a tank having the bottom covered with mercury, the stirrers and mercury being electrically connected. Patents for sluices arranged for electrochemical amalgamation have been issued as follows: 492,711; 669,058; 548,265; 460,722; 307,081; 285,523; 386,030; 641,360; 590,524; 328,532; 757,557. A patent for a system of electrochemical amalgamation was issued to Sir William Crookes on November 3, 1891, No. 462,535. References to electrochemical amalgamation and cyanidation may be found in the following works. Cyanide Process, by E. B. Wilson; A Handbook of Practical Cyanide Operations, by Wm. H. Gage; Practical Notes on the Cyanide Process, by F. L. Bosqui; Electric Smelting, by W. Borchers; Cyaniding Gold and Silver Ores, by H. Forbes Julian and Edgar Smart.

Electrochemical amalgamation may be used in connection with (a) the standard mill plate, (b) mercury wells, or (c) the mercury bath (pan amalgamation). When the usual copper-plate is used, anodes are suspended above it close enough to come in contact with the passing flow of water and pulp, which acts as an electrolyte. The copper plate is connected as the cathode. In the paragraph above, relating to patents, the numbers of several patents granted for electrochemical sluices are mentioned. Electrolytic sluices with suspended anodes require more water than the usual mill-plate. Mercury may be supplied as in the usual practice, or it may be supplied to the water in the form of a solution of bichloride of mercury. A solution of common salt added to the water greatly increases the efficiency of the device. High-grade graphite anodes give the most satisfactory results; there is a grade of graphite made especially for anodes which is superior to the ordinary carbon. A current density of one-tenth to one-quarter ampere per square foot of cathode surface is ample.

Mercury wells such as are described in the second volume of R. H. Richards' work on Ore Dressing can be connected electrolytically and their efficiency greatly increased; some tests were made some years ago in South Africa with mercury wells in which the baffle-plates were connected as anodes, and I am informed that a similar construction is now being used in California. There are several methods of constructing electrochemical mercury wells and many experiments have shown that the electrolytic mercury well is an efficient gold saver; there is no fouling or flouring, and no scum or coating collects on the mercury. Electrolytic mercury wells will extract gold from slime and will recover gold that cannot be amalgamated by the usual methods.

When low-grade pyritic ore is crushed to 100-mesh or finer, practically all the gold is released as free gold; but only a small percentage of the assay-value can be recovered by the usual mill-plate. Gold when in a finely divided state quickly becomes coated with argillaceous, talcose, or sulphurous coverings, and will not amalgamate; very fine gold easily acquires coatings, gaseous or otherwise, which effectually prevent amalgamation. Gold in slime cannot be extracted by the usual mill-plate; particles of gold in placer deposits sometimes have rusty, silicious, or cuprous coatings which effectually preclude amalgamation. With electrochemical methods, these difficulties are overcome. In electrochemical amalgamation a few pounds of common salt should be added to every ton of ore or pulp; by electrolysis the chloride of sodium is reduced to nascent chlorine and nascent sodium. Bichloride of mercury is also added to the solution; this salt under electrolytic action evolves nascent chlorine and mercury. As a result of these reactions, an alloy of nascent sodium and mercury is formed; this alloy absorbs nascent hydrogen produced by the decomposition of the water, and the resulting compound, known as hydrogen-sodium amalgam, has a powerful affinity for gold; in fact no compound known has a more powerful amalgamating action. The water and solutions become charged with nascent chlorine and hydrogen; these gases destroy foul or greasy substances in the pulp; rusty or coated gold is cleaned, the gases mentioned reducing all oxides. Nascent hydrogen reduces oxides at normal temperature. As a result of this cleaning and reducing action, gold particles have been freed from substances that would prevent amalgamation, and amalgamation takes place at the first contact with the mercurial surface.

Those who wish a more detailed account of the chemical and electrochemical processes are referred to a paper on electrochemical amalgamation in the May 1909 issue of the *Electrochemical and Metallurgical Industry*; to *The Mining Journal* (London) for June 12, 1909; and also to Vol. I., page 205 of the *Proceedings* of the London Institution of Mining and Metallurgy.

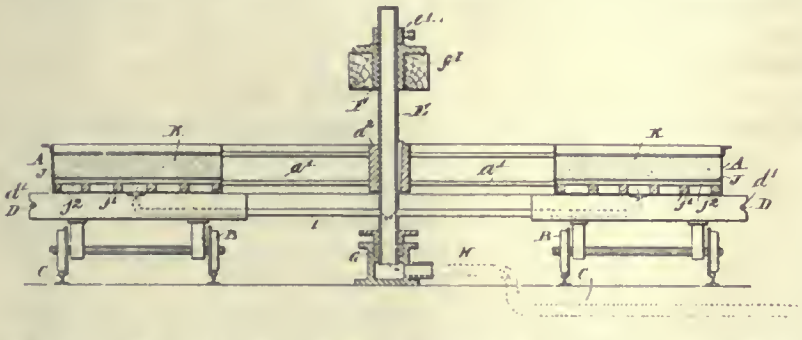
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Vacuum Filtration.

The Editor:

Sir—In your issue of October 9, I note the letters of Edward Parrish and F. C. Frey, on 'Vacuum Filtration'. With the contention of Mr. Parrish that successful vacuum filtration now involves two distinct systems I entirely agree. The first he mentions is suction-adhesion of the solids on the filtering surface, and back-pressure at the exact period when it is desired to dispose of the residue. This I claim is embodied in my patent already referred to in the



MINING AND SCIENTIFIC PRESS of December 7, 1907, being a copy of United States Patent No. 619,211, February 1899. The other system Mr. Parrish refers to I also claim as my invention, and in support of the same I refer to the Victorian Patent granted to me on September 19, 1900, and patented in all the Australian States and in New Zealand. The patents in other countries were abandoned, as I failed to get financial support. I leave your subscribers to judge whether I am right in claiming to be the inventor of the process or method in dispute between Messrs. Burt, Parrish, and Caldecott, after reading the following extracts from the Victorian patent No. 17,559, above referred to: "The improved filtering apparatus * * * consists of a comparatively large annular trough or wheel *A* made with one or more compartments mounted upon a suitably constructed circular frame or platform carried by wheels *B* running upon a circular tramway *C*. Provision is made for rotating this frame by means of an endless driving rope *D* working within a groove d^1 formed for the purpose around the periphery of said frame. * * * The annular trough *A* is connected by spokes a^1 to a boss a^2 keyed upon a central vertical hollow pillar or shaft passing through and working within an overhead bearing. * * * The lower end of this hollow shaft *E* passes through a stuffing-box *G* in a pedestal-bearing from which a pipe *H* leads to a vacuum-pump, while radial suction-pipes lead from said hollow shaft to different points in the bottom of the annular trough. In this latter are arranged a number of battens j^1 and slats j^2 carrying a filter cloth *J* upon which rests a filter bed *K* of sand, which material I have found offers special facilities for the automatic removal of the slime as hereinafter described.* * * At any convenient distance from the slime-feeder I arrange a wash-water discharge-pipe across the upper surface of the annular filter-bed and provide said pipe with a number of holes or jets whereby a supply of wash-water may be sprayed on to the surface of the slime, a deflector plate being used to ensure an even supply of water. * * * Means are provided for automatically removing the layer of slime from the surface of the filter-bed after it has been subjected to the operation of the filtering apparatus. These means comprise an inclined scraper pivotally supported at its rear end, and fitted at its forward end with an adjusting screw whereby the height of the lower forward edge of the scraper may be raised or lowered.* * * With a filtering apparatus such as that above described the slime will be fed on to the surface of the annular bed or filter-sand in an even and regular manner * * * and will be subjected to the action of the jets of water, * * * and the liquid contained in such slime, together with such wash-water, will be withdrawn by the atmospheric pressure upon the surface of the slime into the suction pipe *H* * * * for treatment in the ordinary manner. After the liquid has been removed in this way the layer of dry slime will be automatically removed from the surface of the filter-bed by the inclined adjustable scraper, * * * the height of sand on the filter-bed being removed by the delivery of sand from the sand-hopper."

Referring to my claim that I was the inventor of the first process mentioned by Mr. Parrish, namely, using a vacuum to cause the solids to adhere to the filtering medium, and at the desired period cutting out the vacuum and using back-pressure with the double object of disposing of residues and rendering the filtering medium again porous, I may mention that I have submitted my specification to two of the most capable men here, Professor Masson, of Melbourne University, and B. A. Smith, a leading consulting engineer. Both their reports uphold my contention.

After giving brains, time, and money to this, one naturally says, "What is the good of a patent? Is it simply a Government institution to put people at loggerheads and to encourage litigation?" I do not intend these remarks to apply to the patent office of any one country, as there has recently been an instance here (in the Commonwealth) of an important metallurgical patent, namely, the Potter process. After litigation extending over some years, and costing over £20,000, the Privy Council, the highest court of the British Empire, gave a verdict in favor of Potter, but the inventor himself is in his grave. The only thing Potter got out of his invention was worry and anxiety. So far my experience has been the same. Might I suggest for the consideration of international patents' committees that patents be granted with arbitration clauses where they overlap, but only for application in the case of the subsequent applicant introducing new and valuable matter. This would relieve many difficulties.

ASKIN NICHOLS.

Melbourne, Australia, January 6.

Regenerating Copper Cyanide Solution.

The Editor:

Sir—In his communication, in your issue of February 5, Isaac Anderson, commenting upon my experiments with acid regeneration of cyanide solutions, says that one "will get the same results day after day if the acid is not used in excess," and adds that I evidently used an excess of acid; apparently basing his assumption upon my statement that the hydrocyanic acid evolved raised a part of the precipitated simple cyanides to the surface of the solution. I assume, of course, that, by 'excess', Mr. Anderson means any amount of acid above that required to effect complete precipitation. The context, in his communication, preceding the statement quoted above leads me to believe also that the 'same results' refers rather to the recovery of the dissolved metals than to the regeneration of the cyanide content of the solution, the latter being the chief result desired from the tests which I made.

I did use an excess of acid, although it was comparatively slight, because my approximate methods of determining the essential proportions of acid and solution, and of measuring them, necessitated by the conditions under which I was working, did not permit of great accuracy, and, furthermore, my experi-

Column G. Remarks on physical appearance of column D solutions.
Columns B and D. Solutions filtered before titrating.
Columns C and E. Acid precipitate filtered from solution before addition of NaOH. Alkaline solution again filtered before titration.

*Solution acid after titration. †Solution acid before titration. ‡5 c.c. per litre to effect complete precipitation.

ments seemed to show that, while the addition of the proper amount of acid required to effect complete precipitation produced the best net results, when cost and regenerative effect were both considered, an excess gave results nearer the maximum than could be secured with a corresponding insufficiency of acid. In fact, the chief disadvantage of an excess seemed to be the cost of the additional acid and lime, or of caustic soda, required.

Furthermore, in regard to the escape of hydrocyanic acid and the consequent rise of a part of the precipitate to the surface of the solution as an index to the presence of an excess of acid, it appeared to me that some hydrocyanic acid was given off before the precipitation was complete, and this does not seem to be contrary to theory if the chemical reactions which take place are similar to

$$K_2Cu_2Cy_4 + H_2SO_4 = K_2SO_4 + Cu_2Cy_2 + 2HCy.$$

To obtain some further evidence upon this point, as well as upon the relative effects of insufficiency and excess of acid upon the regeneration of the cyanide content of the solution, I have made a few additional tests, the results of which are set forth in the accompanying table. I found that the same results were obtained day after day in so far as the freedom of the resultant solution from dissolved metals was concerned, but, of course, the amount of cyanide and precipitate recovered naturally depended upon the amount of double cyanides in solution. At the plant where my experiments were made, a limited sump-capacity prevented the manipulation of the solution so as to obtain the possible maximum content of soluble double cyanides in the solution to be regenerated. The addition of wash-water, precipitation of copper in the zinc boxes, and loss of copper-bearing solution with the discharged tailing, seemed to keep the copper-content of the working solutions at 0.5%, or slightly less. A freshly regenerated solution, upon being used, would quickly take up copper to the amount of about 0.25%. The percentage of copper, with further use of the solution, would increase more slowly until the apparent normal balance of about 0.50% was reached. This was the approximate copper-content of the solutions used in my experiments. Just what relation this percentage bears to a saturated solution I do not know. Mr. Anderson states that 80% or more of the potassium or sodium cyanide, as the case may be, can be restored in a saturated solution, and the wording of his sentence seems to warrant the inference that he means that this result can be obtained by precipitation alone. If, as seems to be the concensus of opinion, the reaction for copper is approximately as above, and similar for other common metals, a recovery of but 50% of the cyanogen of the dissolved double cyanides is theoretically possible by precipitation alone. My experiments showed, however, that the recovery of a large proportion of the remaining 50% was possible by subsequent treatment of the precipitate. I trust that Mr. Anderson will not take offense at my criticisms, as the impelling motive for this communication is merely to gain information.

R. P. Wheelock.

Searchlight, Nevada, February 22.

The State Mineralogist Again.

The Editor:

Sir—In November of 1909 a remarkable circular, ostensibly in the form of an interview, was sent broadcast by the California State Mining Bureau; it contains an attack on the United States Geological Survey on account of alleged delay in publishing the figures of the gold and silver production for 1908. It states in substance that the statistics in question were formerly issued by the Bureau of the Mint about July 1 each year, but that since this work was turned over to the Geological Survey the statistics are each year longer delayed. The State Mineralogist is uncertain whether this should be charged to incompeteney or carelessness. While the circular is not signed, it was evidently written and distributed by L. E. Aubury, who still appears to be State Mineralogist of California. It would be charitable to suppose that the misstatements in the circular are due to ignorance. The assertion that the final figures of the production of gold and silver were always issued by the Bureau of the Mint about the first of July of each year is erroneous. The Bureau of the Mint has always given out these final figures in October or November. The statement that "about three years ago the Mint turned the work over to the Geological Survey" is again erroneous. The Director of the Mint, now as always, ascertains the gold and silver production from the statements of Mints and refineries. The Geological Survey, since 1904, ascertains the detailed production of each State, by counties and mining districts, through direct correspondence with the mine owners. Statisticians understand well that figures obtained from Mints and refineries will never quite agree with those obtained from the primary producers. The tabulation of the detailed statistics collected by the Survey is completed in the summer months, in July or August, but they are not published until opportunity has been afforded to compare them with the data of the Mint, as errors made in the returns of refining companies or producing mines can often be detected by such comparison. The Geological Survey has no authority over the Bureau of the Mint, and naturally waits until that Bureau is ready to compare and finally to issue the definite figures, which, as stated before, has always been done in October or November. The circular also contains some absurd statements in regard to the relative service to the public of the Geological Survey and the State Mining Bureau, but I do not think it necessary to occupy your valuable space with a discussion of these points.

Waldemar Lindgren.

Washington, D. C., February 18.

The Katanga district, according to G. B. Beak, is widely mineralized and there is undoubtedly much good ground outside the concession. Abundant water-power is available. Besides the deposits of copper and tin, diamond pipes have been discovered on the Kundelungu and the West Lualaba. Quartz veins are present and payable gold probably will be found. For many years the district will be dependent on the Rhodesian railway system for transportation of supplies.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Creosoting timbers should be done at a temperature of about 160°F., and under a pressure upon the oil of from 100 to 120 lb. per square inch.

Micrometer measurements of precious-metal beads obtained in cupellation are liable to greater error in proportion as the ratio of silver to gold in the alloy increases.

Drill-holes in driving adits or levels of large section in ordinary hard crystalline rocks, should not exceed a total of 5, and may often be reduced as low as 3 ft., per cubic yard of rock excavated.

In pile driving, that the force applied must be greater than the resistance, is a primary principle. If, for instance, a 3000-lb. weight is placed on top of a pile, the pile goes down until the resistance equals 3000 lb. and then stops.

The Tennessee Copper Co. has returned a total of $2,275,000 in dividend on a capital of $5,000,000, par value $25 per share. The mine produced 14,000,000 lb. of copper in 1909 at a cost of 10.59c. per pound, and earned about $2.50 per share on its stock.

Coal production is estimated to amount annually to more than one thousand million tons, of which doubtless more than one-half is utilized in industrial operations. This means that between one and two million tons of coal has to be handled every day in the year, and that the ashes produced by its combustion have also to be handled, removed, and deposited elsewhere.

Shavings are used occasionally in boilers to reduce scale. The coloring matter and tannin combine with the calcium salts and precipitate them in a form which does not adhere to the plates, the woody fibre itself being beneficial in keeping the precipitate from forming a hard mass. On the other hand, the tannic acid corrodes the iron of the boiler, and it is a question which of the two dangers is greatest.

Water-packing is a term applied to a steam-point where one piece of metal slips within another, a few circular grooves being cut in one of the cylinders. The fit must be close, the idea being that the condensed steam in the rings or grooves forms a sort of packing. This system is used on engine indicators, and with some reducing valves of the piston type, where a tight steam-joint is desired and one cylinder must slip within the other.

Drilling hard diabase, having a specific gravity of 2.98, using a No. 34 slugger drill, with air at 90-lb. pressure, was found to average 1 ft. of hole per hour. The rock was very 'blocky', causing the drills to bind and stick badly. This was at Bergen Hill, New Jersey. The specific gravity of this trap rock ranges from 2.85 to 3.04, weighing 179 to 190 lb. per cubic foot. In normal trap the speed of drilling under like conditions is about 1 ft. in 20 to 25 minutes.

The jet condenser is the oldest type of apparatus for producing a vacuum by the condensation of steam, although the idea of a surface condenser was soon evolved for situations in which water containing salt and other substances had to be used, as in marine practice. When pure water is available, however, the immediate contact of the water with the steam still remains as a most effective means of condensation, and its applications are numerous.

Liquid air is produced commercially by the Claude process or by the Linde process at plants in various European countries. There is also quite a large one in this country using the Linde process, in Buffalo, New York. The chief product of these factories is compressed oxygen, and the principal applications of the oxygen are autogenous welding with the oxy-acetylene flame, cutting of metals with the oxy-oxy-acetylene flame, and the manufacture of artificial precious stones.

Powder-consumption in hard diabase in railway tunnel-driving at Bergen Hill, New Jersey, is reported to have been 2.9 lb. per cubic yard of excavation. The quantity used in making the advance at the main working faces was 2.5 lb., the excess being due to the 'trimming' shots on the sides, and blasting the channel for drains. At first 40% Forcite powder was used, then both 40 and 60%, and finally 60% dynamite exclusively. After passing through the diabase into the red sandstone the quantity of powder used increased materially.

Protection from rats in buildings whether in city or in country, is best afforded by the use of cement in construction. As the advantages of this material are coming to be generally understood, its use is rapidly extending to all kinds of buildings. Dwellings, dairies, barns, stables, chicken houses, ice houses, bridges, dams, silos, tanks, cisterns, root cellars, hotbeds, sidewalks, and curbs are now often made wholly of cement. The processes of mixing and laying this material require little skill or special knowledge, and workmen of ordinary intelligence can successfully follow the plain directions contained in handbooks of cement construction. Illustrated handbooks are often furnished free by cement manufacturers.

Lumber is the prevailing material of construction, and this is one cause of the great fire waste of the United States; there is another lying back of this—faulty construction and equipment. The list of causes of fires is headed by defective chimneys, flues, fireplaces, and heating and lighting apparatus—faults of construction and equipment. Matches, sparks, and explosions figure prominently in the list and are followed by incendiarism, electricity, and lightning. Nearly one-fourth of the fires are labeled 'unknown cause', which indicates forcibly the listless attitude not only of the general public toward this waste, but also of the men who are directly charged with protecting property against fire—the officials of municipalities and others.

Special Correspondence.

WESTERN AUSTRALIA.

Historical Summary.—Dividends in 1909.—Development Depth.—Metallurgical Methods.—Geological Survey.

The boom periods of the great Australian mining State, Western Australia, have passed, but there has been no desertion of mining towns nor any general stagnation. Instead the industry is being vigorously developed. It is now a fully established business, and the prospects for the future are brilliant. While it may be open to doubt whether the boom of late years was compensated by results the fact cannot be gainsaid that in the early stages of mining operations in the State, when camps sprang up like mushrooms, operators reaped a rich harvest. The development and productiveness of the mines have been as great as they were meteoric. The gold fever did not really develop until about 1894. It is true that the first return of 270 fine ounces was obtained in 1886, and that the industry was followed with additional vigor during the succeeding 8 years, but it was not until 1894 that production, on what might be termed a highly profitable scale, was carried on. Between 1894 and 1898 the output rose from 185,298 fine ounces to 939,490. After the latter period the million mark was reached. In 1903 the yield was 2,064,801 fine ounces, and although there have been numerous variations in the returns since, the figures have not been below a million ounces per year. The output for 1909 will show a considerable falling off in productiveness as compared with the past few years, and will be the lowest since 1899, in which year the world-famous Kalgoorlie field was opened. As an illustration of the progress of production the following figures are given:

Date.	Fine Ounces.	Value.
Prior to 1897	865,633	£3,686,971
1897	603,847	2,564,977
1898	939,490	3,990,699
1899	1,470,605	6,246,733
1900	1,414,311	6,007,616
1901	1,703,416	7,235,652
1902	1,871,038	7,947,663
1903	2,064,801	8,770,729
1904	1,983,230	8,424,226
1905	1,955,316	8,305,651
1906	1,794,545	7,692,744
1907	1,697,550	7,211,399
1908	1,648,505	7,037,579
1909 (11 months)	1,461,183	5,667,995
Total	21,473,470	£90,790,634

The dividends paid by the mining companies for the current year were:

	1909.	Total to Date.
Associated	£ 49,536	£ 691,449
Associated Northern	52,500	665,000
Black Range	32,625	130,437
Golden Horseshoe	165,000	2,925,000
Golden Ridge	27,812	61,409
Great Boulder Perseverance	70,000	1,426,250
Great Boulder Proprietary	262,500	3,169,300
Great Fingall	21,875	1,696,875
Hannan's Reward	1,748	1,748
Ivanhoe	240,000	2,348,750
Kalgurli	150,000	907,500
Lady Gladys	1,200	2,400
Lake View Consols	17,500	1,431,250
Mararoa	15,000	30,000
New North Boulder	2,100	2,100
Oroya Black Range	15,000	40,000
Oroya Brownhill	45,000	2,146,241
Sons of Gwalia	65,001	580,051
Sons of Gwalia South	12,000	24,500
South Kalgurli	20,000	85,000
	£1,266,397	£18,365,260

The decrease in the gold output is mainly due to the falling off of the yields from East Coolgardie where the mines have settled down to a regular output which provides continuous dividends for the shareholders. This is in accordance with the financial practice observed by the controlling companies.

Developments at the various mines during the year have revealed higher values in depth than previously exploited. The Great Boulder Proprietary has shown that the orebodies continue to at least 2600 ft., and that they maintain their average gold contents. This is the greatest depth in the district from which gold is being won. At 2600 ft. the lode is as wide and as strong as ever. Boring at 2400, 2500, and 2600 ft. has disclosed the continuity of the vein. At 2400 ft. it was 14 ft. wide, 3 ft. of this assaying 22 dwt. per ton; at 2500 ft. the vein was 14 ft. wide and assayed 10½ dwt. per ton, and at 2600 ft. 3 ft. of the vein assayed 11 oz. and 16 ft. gave 5 dwt. per ton.

The Ivanhoe shaft is down 2270 ft. At 1820 ft., where the vein averaged 46s. 3d. in the cross-cut, for a width of nearly 50 ft., a fine shoot of ore has also been opened and the 2120-ft. is also looking well. The east lode, which is world famous, is the longest and most valuable on the Kalgoorlie field. It traverses the entire length of the Ivanhoe lease, and then extends several hundred feet north in the Great Boulder Proprietary ground and south for a greater distance in the Golden Horseshoe, where it is known as No. 3. The substantial increase in the percentage of extraction obtained from the treatment plant is one of the most noticeable features of the work at this great mine.

The Great Boulder Perseverance has devoted much attention to the deeper workings, and payable orebodies have been opened at 1750 and 1900 ft. Two new lodes have also been proved in the upper section of the mine, and are developing satisfactorily. The Perseverance, Lake View, and El Oro veins continue to be the most important bearers of payable ore in the property, and recent work on the old orebodies here yielded and continue to yield good results. Unfortunately the mine has just been visited by a disastrous fire which, besides doing about £400,000 worth of damage to the treatment plant, has caused a cessation of gold production for at least six months.

The principal factor in the present position of affairs on the Kalgoorlie belt appears to be a strenuous effort to maintain the grade of the ore going to mill, under the belief that this secures the greatest profit per ton treated. Large reserves of ore are being developed and considerable sums of money have been spent in this work. An analysis of the figures indicates a desire to maintain the reputation of the district for high-grade ore. The tonnage of ore falling just below the payable limit is not generally given; in fact the policy of the management is conservative in computing the values of ore reserves, and it is to these matters that attention should be directed, for in ore deposits of the character existing in Kalgoorlie it is nearly impossible to determine within, say 5 dwt. per ton, the value of a block of ore, say 150 by 150 ft., and it is this 5 dwt. that must often determine whether or not the block is to be counted in the declared ore reserves. In view of this it would be interesting to know how many blocks classed as payable have been proved to be non-payable, and vice versa.

Regarding the treatment methods, although during the last few years these have been improved in details, there has been no radical alteration of the plants. The efficiency and low costs of slime-treatment by the Cassel vacuum process have made it increasingly popular, and many mines have installed it. Considerable amounts of old tailing which would not pay to re-treat by filter-presses are being advantageously treated by this system. While the Kalgoorlie auriferous belt has contributed more than half of the gold produced in the State the geology of the district has never been properly studied. The reason is obvious. Kalgoorlie sprang up in a night, as it were. There was practically little searching needed to find the precious metal. It was got for the digging. When the baby propositions developed into healthy manhood a geological examination was deemed superfluous. Now, however, several of the mining companies, the Chamber of Mines, and the Government Geological Survey Department, have taken up that work. The result of

the labors of the geologists when made available should establish important facts pertaining to the ore deposits, which will tend toward diminishing the element of chance in prospecting and working the veins and lenses peculiar to this zone.

The position of mining in Western Australia must be regarded as being on a sounder footing than ever. While little outside capital has been introduced for some time, its steady development is almost wholly due to the exertions of the comparatively small number of the inhabitants themselves.

Western Australia possesses a great extent of ancient, pre-Cambrian rocks, covering an area of about 650,000 square miles, or about two-thirds of the superficial area of the State. Gold has been found at intervals over hundreds of miles but the auriferous areas are mostly confined to the ancient greenstones. When it is considered that hundreds of square miles of country are unfortunately covered by a peculiar kind of cement rock rendering prospecting troublesome, coupled with the small population of the State, it is difficult to predict what wealth lies beneath the surface. Moreover, as much of this region is not only unprospected but unexplored, there is undoubtedly a future for the prospector, the miner, and the investor.

JUNEAU, ALASKA.

Winter Work and Spring Plans. — Alaska Treadwell, Alaska Mexican, and Alaska United Reports.

Things are quiet around Juneau at the present time owing to the winter season. At present the mines in operation are the Treadwell group, the Alaska Treasure, Eagle River, and Gypsum Bay. Owing to lack of water-power the Perseverance, the Treadwell 300 mill, the Ebner, and the Alaska Juneau have been shut down since late in November. To this list may be added the Mills and De Groff mines on Chichagoff island, whose mills there have closed since the middle of December owing to lack of water-power. Work is being pushed rapidly at the Alaska Treasure mine on Douglas island. A cross-cut is being driven in from the beach a distance of 3300 ft. to tap the vein. A force of 50 men is employed working 8-hr. shifts. W. H. Priestley, Jr., is superintendent, succeeding D. J. Argall, who resigned late in November. The property of the Birner's Bay Milling & Mining Co. was sold at marshal's sale, the only bidder being the International Trust Co., of Boston; the bid was $800,000. This property has been in litigation for some years. On good authority it is stated that active work will be begun at Birner's Bay this spring. The opening of this rich property will be a source of great satisfaction to many. The Ebner mine, under the management of E. H. Tripp, is to be operated this spring by a new company. A larger mill is soon to be built, according to report. The Haltum group has been bonded by the Ebner. The Perseverance will open in the early spring as soon as its water-power is available, as will also the Alaska Juneau. In January an expert from Denver went to Pearl harbor, near Juneau, and examined John Peterson's mining claims. The outcome of the trip has not been made public, but it is known that a year ago Mr. Peterson bonded his property. The Mills and De Groff mines expect to resume operations some time in March. The Treadwell has built a dam at Sheep Creek, and is now putting in a pipe-line and building a power-plant. The electric power will be transmitted across the bay to Treadwell. With the Ebner, Alaska Treasure, and Birner's Bay mines added to the list of producers, this will undoubtedly be the banner year for the Juneau district. For the month ended January 15, the Alaska Treadwell reported 31,864 tons crushed with a total realizable value of $98,971, operating expenses of $78,136, and construction expense of $12,517. The yield per ton is given at $3.27 and the stock of broken ore increased 50,314 tons. The Alaska Mexican reported 18,312 tons crushed; $81,394 realizable value; operating expenses, $24,955; construction, $3699; yield per ton, $4.58; stock of broken ore decreased, 1209 tons. The Alaska United reported 32,898 tons crushed; $59,582 realizable value; $48,988 operating expense; $3869 construction expense, $1.92 yield per ton from the R. B. claim ore and $1.97 from the 700 claim. The stock of broken ore increased 1035 tons.

JOHANNESBURG, TRANSVAAL.

Big Movement in the Far East Rand.—Rumored Amalgamations. —New Electrical Association.—Cape Colony Labor Recruiting.—Mules Underground.—Coke for Gas Producers.

During the next year or two, there will be no division of the Rand more worthy of close attention than that to the east and south of the New Modderfontein, in the Far East Rand. The New Modderfontein itself is making splendid progress and stands among the 12 leading mines of the Rand. Costs have been reduced to 15s. 6d. per ton, milled. It is reported with seeming authenticity, that capital is to be raised to provide for a further extension of operations, for, although capable of milling today 50,000 tons per month, the mine—as pointed out by the chairman some time ago—can carry a much larger plant and has been scarcely touched in the eastern portion, adjoining the Modderfontein B company. This latter mine is said to be improving and to be showing in development a grade of ore far above the bore-hole results. Here, again, we may expect to see a big plant erected in the next two years. It is further officially announced that the Modderfontein Deep company is raising working funds by increasing its capital from £100,000 to £500,000. In addition to this new point of activity, the Government ground adjoining to the east, recently leased to Barnato Brothers, will soon be the scene of shaft-sinking operations. The Apex mines, whose shaft cut the reef last year, is developing, and the Van Ryn Deep has just reached the reef in its eastern shaft. The ground in this region is all held by strong houses. Four of these being concerned, healthy competition may lead to more rapid development than in the area were dominated by one firm. There are rumors afloat of big amalgamations in the East Rand (Leeuwpoort area) and the West Rand (south of the French Rand). As both schemes appear—according to the rumored details—deserving of keen censure from the mining point of view, discussion must be reserved till all the facts are available.

Rand Mine Laborers as They Enjoy Their Sunday Rest.

The newly formed South African Institute of Electrical Engineers held its inaugural meeting on January 13, under the chairmanship of its first president, C. W. Campbell. There was a large attendance and the new association received the good wishes of several representative bodies. Although the initial membership is satisfactory and there

is good promise of the production of valuable papers, it cannot be said that the organization opens its career under wholly auspicious circumstances. There has been strong opposition to its formation and many of our leading electrical engineers have failed to identify themselves with the body. The reason is clear. Persistent efforts are being made to create one strong engineering society, with sections dealing with the various branches of the profession, but with a common journal. That the electrical engineers would receive full consideration under the scheme has been promised, and it is contended that the formation of a new society at the present time may tend to weaken the movement for the amalgamation of the existing engineering associations. At the same time, the council of the new society does not appear to be opposed to the proposals for unification, but urge that they can obtain better recognition by adopting the present course. Hitherto, it may be observed, the electrical engineers have been served by the South African Association of Engineers, in whose proceedings have appeared some admirable electrical papers. This organization, however, deals as a rule with matters of general policy, with which the consulting man is more concerned than the routine electrician and it is the man of this status who is likely to support the new Institute, just as the resident engineer on the mine is the backbone of the Transvaal Institute of Mechanical Engineers. The electrical engineer certainly demands far greater representation than he has hitherto obtained. Not long ago, his functions were limited to such duties as lighting, signaling, driving underground pumps, and operating minor units of mine equipment. Soon his functions will be universal, covering the operation of all main hoists and stamp-batteries.

The return of free labor recruiting a year or so ago led to the recurrence of many of the old abuses prevalent before the war, and recruiting organizations outside the Witwatersrand Native Labour Association, run on high moral principles, have not been signally successful in their results. Numerous complaints came from the Cape Colony of the dishonest methods of some agents, and it is, therefore, satisfactory that an enquiry has been made. While the Cape Government has introduced measures promising to hold the unscrupulous recruiter in check, the chances of more 'boys' coming forward have been improved. The Transvaal Government will be permitted to establish registry offices at various centres in the Colony, where registrars will control the dispatch of boys up to the mines. These officials will further examine the terms of the contracts under which the 'boys' have been recruited, seeing that they are thoroughly understood, and they will investigate any grievances expressed. Native messengers will also be sent around the country to make known the new protection afforded, and thus inspire confidence where none has, often with good cause, formerly prevailed. The shortage of native labor (which the optimists tell us will soon be over, largely because the December returns showed a gain after a succession of heavy wastages) has led to various schemes for economizing underground, and the Robinson Deep has adopted the employment of mules for mine tramming. This practice is almost novel to the Rand and is to be regarded with doubtful favor. As a general rule, the drifts are not sufficiently well laid out for mule transport, and there is rarely the opportunity of providing the beasts with well ventilated stalling accommodation. Further, if the company wishes to be clear of prosecutions, it must be extraordinarily careful in the choice of mule drivers, for the Kaffir would be a cruel master under these trying and ill-supervised conditions, and would not appreciate the necessity for care in the treatment of the animals, working and living in poor air. A good mule costing $200, the dangers of the innovation are obvious, but when it is a question of mules or nothing (a point of view that does not say much for the Robinson Deep's opinion of the unskilled white labor available for tramming), the factor of comparative economy is ruled out of the question. As an alternative scheme, the New Modderfontein is about to employ a petrol locomotive for underground haulage. This system is new to the Rand, and it is, therefore, satisfactory to find that it will be tried at a soundly run mine like the New Modderfontein, and not at one of those many properties which are so well managed that they can show a 10d. per ton reduction in costs by the employment of any scheme introduced from quarters it is found desirable to please. If oil locomotives are as useful underground as the oil furnaces for drill-sharpening, there will be no cause for complaint. We are still hankering after an electric-drill sharpener, to enable us to regulate the temperature with exactitude for the different classes of steel, but until this comes the oil furnace will continue to give satisfaction.

I must again give the *South African Mining Journal* a kindly hint as to the advisability of investigating the reasonable chances of accuracy in the reports it publishes in its editorial columns for syndicates. The 'facts' generally cannot be confirmed, but where the information is self-condemnatory it should not be printed without comments. In the *Journal's* issue of January 22 appears a report on the Vesta gold mine (a 'Black Reef' proposition) which is expected to start milling shortly. It is noted that "samples taken at various points give the following values—No. 1, 8 ft. from outcrop, 52 dwt. over 10 in.; No. 2, 60 ft. south, 54 dwt. over 12 in.; No. 3, 80 ft. south, 17 dwt. over 16 in.; No. 4, 84 ft. south, 105 dwt. over 12 in.; No. 5, 88 ft., 36 dwt. over 24 in.; No. 6, 170 ft., 24 dwt. over 17 in.; No. 7, 38 ft., 131.4 dwt. over 16 in. It will be observed that this represents 23.97 dwt. over a stoping width of 36 in., equivalent to a recovery value of £4 9s. 6d. per ton". Accepting the accuracy of this sampling, it will be seen that the average value of extraordinarily irregular sampling is taken to indicate the probable yield. Between samples called 1 and 2 (were there none between, and if so, of what value?) there is a distance of 52 ft., then comes a gap of 20, then three samples are taken within 8 ft. (no doubt a rich little pocket) following by the next 82 ft. away. Of course, the averaging of such returns is ridiculous for estimating probable yield, and especially for the patchy Black Reef, which will characteristically show an ounce sample between two 'traces' 10 ft. on either side. If the Vesta averages a yield of 6 dwt. it will be lucky.

F. W. Harbord, the British expert on iron and steel, studying the Transvaal iron resources for the Government, has completed his examination of the deposits, and is now going into the question of coking coal. It is doubtful if there is coal of the quality required to give a strong coke suitable for blast-furnace work. Mr. Harbord has stated, however, that our coal provides coke of high utility from the gas-producer point of view, and has suggested that there is room for useful developments in this direction, in the supply of cheap power for the operators of small units.

LONDON.

Cornish Tin Dumps. — Radium at Trenwith. — Wheal Kitty. — Cornish Geology.—Santa Gertrudis Flotation.

An interesting project has recently been undertaken in connection with the re-working of tailing heaps in Cornwall. A company called the Cornish Tailings Co. has been formed with a nominal capital of £40,000 for the purpose of purchasing accumulated dumps on the Carn Brea and Tincroft ground. So far the capital subscribed is £5000. The proposition to undertake the work came from Arthur Richards, a mining engineer of experience in various parts of the world, and the money has been put up by the Anglo-Australian group identified by the names of Baillieu and Lempriere. There is not room on the property to erect a treatment plant, so a wire-rope tramway is being built to convey the tailing to the old dressing-floors on the neighboring mine, Wheal Agar. It is estimated that the content of the dumps is from 7 to 9 lb. of black-tin per ton. The present price of black-tin is about 9d. per pound, so that the value of the dumps will average 6s. per ton. It is calculated that the dumps contain over a million tons of tailing. The question as to economical treatment requires narrow calculation. Transport, re-grinding, concentration, royalty, and profits will have to be figured closely, and the fluctuations in the market price of tin will have to be carefully followed. I think it is a scheme which stands a good chance of success; at any rate, the people connected with it have had ample

experience and are not likely to go into anything without being satisfied that the enterprise will win. A word of explanation should be given concerning the existence of such dumps. It is not through the superior wisdom of past managers of Carn Brea and Tincroft that these dumps are still in existence. They would have been dispersed along with the other tailing by being discharged into the Red river if there had been sufficient water-supply. The content is a trifle higher than has been discharged in the tailing during recent years, as the ore is now leaner than formerly. I reckon that the tailing discharged by the various mines into the Red river runs 5 to 6 lb. of black-tin per ton, and if the many streamers can make a profit by re-treating this tailing there is no reason why the present company should not do so also.

A few weeks ago I mentioned that the National Minerals Corporation had acquired the West Kitty at St. Agnes, Cornwall, and I traced some of the incomplete schemes belonging to that company. Since then the company has made an announcement relative to the St. Ives Consolidated Mines, which was formed a year ago to acquire a number of tin properties in the neighborhood of St. Ives as well as the Trenwith mine, which is notable for its production of pitchblende, and for its inferential content of radium. As I mentioned before, the directors have already established a laboratory in London where Sir William Ramsay is to produce radium. The latest announcement is that the Trenwith waters have been found to be radio-active, and that they are therefore suitable as a basis for the establishment of a 'spa.' No doubt we shall hear before long of the foundation of a sanitarium or a 'hydropathic', and the Great Western railway will boom the general curative powers of the town. St. Ives was once a busy centre of mining and fishing, but the pilchards deserted it soon after the decline in tin, and at the present time it has shrunk to a smaller estate. Efforts have been made to bring back prosperity by singing its praises as a watering place, but the accommodations are poor, and with the exception of an excellent golf-course there are no attractions. Besides, the dynamite manufactories on the opposite side of the bay form conspicuous landmarks that are not conducive to the peace of mind of invalid visitors. As regards the tin mining prospects at the St. Ives Consolidated mines, it is reported that many of the old workings, both shaft and adit, have been cleared, and a large central electric generating station has been erected. At first the power will be used for electric pumping with the object of unwatering below the adit.

While writing of West Kitty it is of interest to note that its neighbor, Wheal Kitty, is doing excellently. This mine was rescued from oblivion three and a half years ago by J. H. Collins, who found the necessary capital among his friends and re-opened the workings. The price paid for the property was £13,000 in shares, and work started with £8000 cash capital. Subsequently the capital was increased by another £5000, besides which, £5800 has been provided out of revenue for capital expenditure. During this time £3000 has also been distributed as dividend. The yearly output is rather over 12,000 tons, and the concentrate sold was 241 tons of black-tin during 1909. From this the income was £20,508. The economy of the management may be judged from the fact that the cost of directors' fees, management, secretary's salary, office, and general expenses was only £650 during the year. At various parts of the mine some excellent ore has been exposed, and in the southern portion near the boundary the lode is so promising that the adjoining Gooninnis property has been leased. Operations would proceed faster if the new main shaft were complete, and several of the shareholders have intimated their desire that the necessary capital should be at once subscribed. Without this Mr. Collins has had to proceed as best he could in the sinking of the shaft by applying some portions of each year's profits to that purpose.

Much amusement has been caused by the description of Cornish geology that appeared in a recent article on the Dolcoath mine in your Chicago contemporary. The writer says that the southwest extremity of England consists of a great expanse of old red sandstone. The reason for making such a queer statement is probably that the rocks are Devonian, and among this division is included the old red sandstone. The latter, however, only occurs in Scotland, as readers of Hugh Miller will know. Cornwall is composed of slate, and in Devonshire the Devonian series includes also some millstone grit, forming the scenery of Lorna Doone's country. In the Plymouth and Tavistock districts the rock is limestone. One of the geological features of Devonshire that confuses the visitor and the casual student is the existence of bright red cliffs on the coast south of Exeter. The observer immediately jumps to the conclusion that, as he is in Devonshire, the red rock must be Devonian, and therefore old red sandstone. It is, however, a different deposit, and belongs to the Permian. The writer in Chicago also says that "the sandstone at the junction with the outcrops of granite is covered with Killas, that is, hardened mud deposits derived from recent detritus of the granite." The word 'Killas' really means the slate in the vicinity of the granite, that has been contorted and metamorphosed by contact with the igneous intrusion. He also says that the "whole district is intersected by dikes of basalt running east and west, and curiously parallel." He presumably refers to the elvan dikes which consist of granite-porphyry. His geography is also at fault, for he places Camborne and the chief tin deposits in the north of Cornwall.

The successful issue of new shares by the Camp Bird company for the purpose of acquiring a controlling interest in the Santa Gertrúdis silver mine at Pachuca, Mexico, was one of the most important recent events in the London mining market. The company published a prospectus offering for subscription £500,000 of 6% debenture stock at 97½, and 280,000 £1 shares at £1 7s. 6d. The capital of the new Santa Gertrúdis Co. is £1,275,000, of which the Camp Bird will acquire by purchase 1,155,822 shares, £259,631 being provided out of the reserve fund, and the remainder out of the present issue. The Santa Gertrúdis Co. was formed to acquire the controlling or aviadora rights of the silver mine of that name in Pachuca, and the purchase price is ₱9,000,000, or £922,131. After this price is paid the company will have a working capital of about £150,000, which will be spent in further development in depth, and in the erection of a modern mill and cyanide plant to treat 160,000 tons per annum. The mine was discovered in 1876, and has been worked successfully by a local company, although the methods of treatment were out-of-date and expensive, the patio process being used. The adjoining mines, La Blanca and Barron, working on the same vein, have also been successful. The Santa Gertrúdis vein is large and persistent. It consists of friable quartz, and the valuable mineral is sulphide of silver, which contains some gold. There are practically no base metals present, so that cyaniding will give high extractions. The country rock is andesite. The vein varies from 10 to 30 ft. wide, and has been developed for more than a mile in length. The main ore-shoot has averaged 2500 ft., extending through the three mines. Within the Santa Gertrúdis ground is another smaller orebody, and the indications are that this will join the main orebody in depth. The main shoot has been worked down to the 1000-ft. level. The average content of the ore now available for stoping is 32 oz. silver, and ¾ dwt. gold, and the average value is about $20 gold per ton. The mine has been carefully sampled, and it is reported that 308,043 tons of 'positive' ore exists that will yield $2,565,055 gold profit and 218,240 tons of probable ore that will yield $2,714,906. The cost of treatment by a modern plant will be about $11 gold per ton. The petrological examination of the vein and country rock shows nothing to indicate any change in depth. The examination of the property was undertaken by W. J. Cox, manager of the Camp Bird. E. E. Chase, of Denver, did the sampling, F. J. Pope made the geological report, G. Doveton advised on metallurgy, E. E. McIntyre, of the Guanajuato Development Co., reported on the cost of mining, and R. J. Frecheville, one of the directors of the Camp Bird company, has visited the property and given his views. The issue of these shares and debentures was underwritten, partly by L. Hirsch & Co., and partly by the Canadian Agency, Ltd., one of Chaplin, Milne, Grenfell & Co.'s companies.

MEXICO.

Zacatecas Custom Mill.—San Roberto Mine. — Palmilla Mill. — Oil Concentration at Santa Barbara.—Largest Filter Plant.

The State of Zacatecas is now engaged in custom milling, having a fifth interest in the custom concentrating and cyaniding plant recently built just north of the Zacatecas capital, and there is promise that the money invested with the object of encouraging mining in the old Zacatecas district will bring substantial returns to the State. The plant was recently placed in commission, a number of trial runs have been made with satisfactory results, and the machinery will be soon adjusted for steady operation. The response of the mining men of the district has been so general that the management of the plant has been compelled to decline ores until such time as additional storage facilities can be provided. The equipment of the custom plant consists of a 9 by 14-in. Blake crusher, two 5-ft. Bryan mills, one Card and two Wilfley tables, a tube-mill, 5 by 14 ft., six Risdon-Johnson tables, four Pachuca tanks, a Butters filter, and zinc-boxes, the whole having a capacity of 60 to 75 tons per diem. There is already talk of doubling this capacity. The facilities for handling custom ores will be materially increased during the present year, as plans are being made for custom work at three other reduction plants in the Zacatecas district. Theodore Van Wagenen and the Cape Copper Co., of London, have surrendered an option on the

Zacatacas.

San Roberto mine in the Zacatecas district, and the property is again in the hands of the owners, J. A. Petit and C. A. Bentiy, who will continue development. Shipments of high-grade ore have been made from the San Roberto during the past several months, the ore yielding unusually high gold values. The Zacatecas Syndicate, Ltd., controlled by the Goerz interests of London, is working night and day shifts on a 3-compartment shaft on property acquired last year near the Villa de Guadalupe, in the Zacatecas district. This is the second shaft started, and soon work on a third will be commenced. An option on the Santa Rosa mine in the Concepcion del Oro district of Zacatecas has been taken by the Exploration Co., Ltd., of London, and extensive development is planned. The control of the mine is held by the Victor Clement estate. Milling soon will be resumed by the reorganized San Carlos Gold Mine, Ltd., of London, in the Mezquital del Oro district of Zacatecas. The 50-stamp mill and cyanide plant are being placed in shape for operation. The ore reserves are estimated at 120,000 tons.

The first 250-ton unit of the 1000-ton plant of the Palmilla Milling Co. (Alvarado Consolidated), now under construction in the Parral district of Chihuahua, will be completed not later than next September. The equipment ordered for the plant consists of three 9 by 15-in. Blake crushers, six 10-stamp batteries, 12 concentrating tables, 3 tube-mills, 5 by 22 ft., 24 vanners, 6 Pachuca tanks, filter-press, and the usual zinc boxes. A power plant of three 300-hp. compound engines, and three 250-kw. alternating current generators, will be installed. The reduction plant was designed by Bernard MacDonald, of Guanajuato, and will be one of the most complete in Mexico. The American Smelters Securities Co. has completed a zinc mill at its Tecolotes y Anexas mines at Santa Barbara, and if it proves successful the capacity will be doubled. The Tecolotes reduction works are now handling nearly 700 tons daily. The Arizona-Parral Mining Co. has been organized to operate the properties of the American Zinc Extraction Co. in the Parral district. A plant for the Elmore process of oil concentration was recently installed. The second annual report of the Rio Plata Mining Co., operating the Santa Barbara silver mines near Guazapares, shows an income of $214,905 for the year ended November 30, 1909, and profits of $97,766. The company paid a dividend of 1½% in December, and it is expected to pay a similar dividend each quarter.

The Cometa mine in the El Oro district of the State of Mexico, immediately adjoining the property of the Mexico Mines of El Oro, has been taken under option by the Exploration Co., Ltd., of London, which controls the Mexico Mines and the El Oro Mining & Railway Co. The option has three years to run, and if it be determined that the main vein of the Mexico Mines continues into the Cometa, as is believed, the property will be purchased. The Mexico Mines development has uncovered valuable orebodies within 400 ft. of the Cometa line. The January production of the great Dos Estrellas mine was ₱766,673, and the expenses ₱324,989, leaving a profit for the month of ₱441,683. A 100-ton Butters filter-plant is nearing completion at the Dos Estrellas mill. This is the largest filter-plant in Mexico.

GOLDFIELD, NEVADA.

February Report of Goldfield Con.—Heavy Production. — Active Development.

The preliminary report of operations of the Goldfield Consolidated for February, 1910, shows tonnages of ore produced as follows: from the Combination mine, 6034 dry tons, assaying 0.86 oz. gold; from the Mohawk, 7370 tons, 0.86 oz.; Red Top, 5988 tons, 1.57 oz.; Clermont, 4474 tons, 3.20 oz.; making a total of 23,866 tons, assaying on an average 1.49 oz. gold per ton. The approximate value produced was: from the Combination, $109,034; from the Mohawk, $131,010; from the Red Top, $194,322; and from the Clermont, $295,554, making a total of $729,920. The loss in tailing was $45,692, and the estimated recovery $684,291, the percentage extracted being, therefore, 93.74%, and the average net production per ton $30.59. The total costs, including losses, were $244,422, or $10.24 per ton, leaving a profit per ton of $20.34, making a total of $485,498, the percentage of net earnings to gross recovery being 66.5. The costs are distributed as follows: bullion tax and marketing, $14,000; general administrative expenses, including corporation and legal expense, damages, taxes, etc., $13,000; mining, $95,569; transportation, $3424; milling and cyaniding, $55,800; marketing concentrate, $17,000. The total cost as outgo was, therefore, $198,795, which, with the tailing-loss of $45,629, makes $244,422. The mine produced ore of more uniform grade and at lower cost than in January. The mill treated a larger tonnage with a better extraction, and the company realized larger daily profits and a higher percentage of profit on the ore mined. The advance at the various mines was as follows: Combination, 419 ft.; Mohawk, 795; Clermont, 1135; Red Top, 1050, making a total of 3399 ft. The advance was less than in January, but the results were more fortunate. The development proved the following approximate amounts: Clermont, between the 900 and 1000-ft. levels, 17,000 tons, assaying $20 per ton; above and below the 750-ft. level, 14,000 tons, $44; above the 600-ft. level, 18,700 tons, $10; for the Red Top, above the 330-ft. level, 2000 tons, $14; giving a total of 51,700 tons, assaying $22 per ton. This ore is duly developed on two sides, and some of it only on one side. It cannot, therefore, be called more than partly developed ore, and any estimate, either of tonnage or values, may go astray. It seems fair to say, however, that the developments for January and February have been, by a considerable margin, in excess of extraction, both in tonnage and in value. The 1000-ft. level of the Clermont is developing favorably. About February 18 a small seam of good ore appeared. It assayed from $10 to $1000 per ton for a few rounds, but was too small to make the drift profitable. About February 25

the streak began to show improvement both in size and value, and for the last two days of the month the car-samples showed good ore, 40 tons averaging $33 per ton. There is reason to hope that this ore-shoot may prove better on the 1000-ft. level than on the 900. A development that cannot be other than important is the discovery, in the last two days of February, of the continuation of the Mohawk ore-shoot on the 750-ft. level of the Clermont. The vein is 8 ft. thick where intersected in a cross-cut southwest of the large Clermont orebody. The samples taken from the face assay from $20 to $30, but the car-samples taken thus far show an average of only $9. The latter ore must have been mixed with a good deal of waste.

NEW YORK.

Copper Mines and Metal. — Cobalt.—Goldfield Con. Love Feast.

The quarterly report of the Nevada Consolidated Copper Co. has just been received. It shows production for the last quarter of 1909 to be 12,969,761 lb. of copper produced from ore averaging 2%. The Cumberland Ely is still closed, while, as yet, there has been no production from the Ruth. The payment of the first dividend of 37½c. was made during the period covered by the report and a similar dividend has been declared for the current quarter. A wire from C. B. Lakenan, of the Nevada Con., gives the February production as 7700 tons of carbonate and 4,600,000 lb. of blister copper. The ore milled during the month was 165,000 wet tons, averaging 2.3% copper. Copper costs, Mr. Lakenan figures, at 7.24c. per lb. It is evident that Nevada Con., for the present, is to retain its identity. There has been a little talk of a possible campaign to be made by Utah Copper people to get the control in the open market. This is an absurdity. While Nevada Con. enjoys a fairly active market, it is, in reality, closely held and the amount of floating stock is relatively so small that any attempt to accumulate shares would be apparent at once. The Utah Copper Co.'s output for January is reported at 4,700,000 lb. of copper. Some of the shareholders are subscribing for the new stock under their rights in order that they may receive the April dividend, which, it is officially announced, will be 75c. per share. Utah Copper shares in the open market have been selling either under or so near the subscription price that there has been no market whatever for the rights. The decline in North Butte was accentuated this week by the cutting of the dividend from $1 to 50c. In most of the other Butte issues there have been advances, especially in Amalgamated and in Anaconda, which have been in process of accumulation for merger purposes. The appraisal of the various Butte properties by B. B. Thayer, president of the Anaconda, and his corps of assistants is to be an interesting piece of work. Up to the present time there has been no official announcement of just what properties are to be included in the new Anaconda, though it appears certain that Butte Coalition is to go in and equally certain that North Butte is to be left out. While there has been little outward evidence of negotiation, it is understood that the Anaconda, after absorbing the various properties now in view, will be, and is now in the market for any and all of the younger proved properties in Butte. These include East Butte, Butte & Superior, Butte & Ballaklava, and Tuolumne. The last named is especially needed by the new merger as it could be worked simply as an extension of the North Butte, and it would be possible to sink the apex trouble between the two companies in the merger. There has been a vast amount of copper ore extracted from Butte Hill in the years gone by and the revamped Anaconda will need something more than empty stopes with which to make a record that will atone for Amalgamated. The lessened production of the Butte mines for February aided somewhat the favorable anticipations in regard to the Copper Producers Association's figures covering February's production and consumption. Were it not for the preparations everywhere for record breaking production, copper metal ought to strengthen rapidly. European visible supply as of March 1, 1910, is reported at 113,460 tons as against 114,100 tons on February 15, 1910, while the reduction, in itself, is not large enough to be important, its significance lies in that there was any reduction at all, in view of the recent heavy exports from this side. A sale of 5,000,000 lb. of Lake copper, for export, was reported today, at 14c. per lb. Electrolytic for May delivery is selling at 13¾c. The improved statistical position of copper has resulted in an increased demand and a much brisker market. The American Smelting & Refining Company is said to have withdrawn all offerings for the present.

The flotation of the North Indiana, a Michigan copper property, in which Charles S. Herzig and W. Murdoch Wiley were interested, has been withdrawn and the same parties have taken up the flotation of a piece of ground at Houghton, Michigan, to be known as the South Quincy. The village of West Houghton is situated on a part of the property, which it is proposed to develop.

Cobalt is looking forward to a year of large accomplishment. The hydro-electric plant, which is to deliver power from the Montreal river, is just completed, and as current is made available each mine is expected to push development which has been held back waiting for power. Cheaper power is expected to make profitable large quantities of ore, which hitherto could not be handled at a profit, and, in this way, will go far to make for the permanence of Cobalt. Kerr Lake is paying a dividend of 50c. per share. Crown Reserve reports a production for 1909 of 4,034,325 oz. of silver from 3092 tons of ore. Gross value of bullion produced was $2,080,156, net profit was $1,664,015. The management claims for the Crown Reserve a production equivalent to one-sixth of the total output of the Cobalt camp, and states that there is much more ore in sight in the mine now than there was a year ago.

George Wingfield entertained the Goldfield Consolidated directors at a 'love feast' at the Waldorf this week. Among those present was Charles Hayden, the Boston broker, who last spring was invited to resign from the board. Hayden sold his own stock and took his own friends out a year ago believing that the value of the ore would not extend from the dacite into the latite formation. Now, that development has proved that the veins carry high gold values in the underlying latite formation, Hayden has 'made up' with former fellow directors, and Boston is said to be again buying the stock.

LEAD, SOUTH DAKOTA.

Guarding the Homestake Plant.— New Laborers. — Resumption of Mines and Mills.

All the trains in and out of the Black Hills now carry detectives, so-called 'Pinkertons', and each daily quota of new arrivals of men for the Homestake mine is convoyed by these guards. Many union men are leaving. These are mostly foreigners, with some old-timers and their families. With the exception of a few individual brawls and fist fights there has been no trouble, and the union seems to be whipped to a point of bewilderment. Mr. Kirwan and others of the Western Federation of Miners are still directing their forces, but all their moves seem to have been anticipated and checkmated by the Homestake management. The property is well guarded, two detective agencies having charge of that work, and the guards have practically a military organization, whereby all outlying pipe-lines, power-lines, mills, and property of every kind, is patrolled and watched continuously, the guards being increased at night. There are some noted fighters among these guards, such as Mr. Bartell, the bodyguard of Orchard during the Boise trial, and many men who have gone through the Western Federation fights in Colorado, Nevada, and Idaho. Unless vigilance is relaxed, it would seem difficult to damage any of the property. Of course some fanatic might do injury from a distance to a chief or to T. J. Grier. Naturally, all these men are under a great tension. Mr. Grier goes about as usual, often accompanied by his wife, and generally followed by a guard at a distance. At night a searchlight from the roof of Ellison hoist plays over the town and works, making it possible to distinguish men as far as the Highland hoist.

Mill street is always crowded, mostly with new men looking for work. These new arrivals, who are nearly all

American miners from the Kansas, Wisconsin, and Missouri lead and zinc fields, tax the capacity of the town for housing and feeding. Both sides occasionally display their streagth at a funeral. The Union could muster about 1200 men, mostly Slavonians, Finns, and Swedes.

On February 22 there were about 2300 men on the payroll, and the new men were coming in faster than they could be used in the mine. It is necessary to break in the men to the Homestake mining methods. To avoid accidents, the management wants to go slowly. On February 24 the following mills were at work: Amicus, 240 stamps; Star, 200 stamps; Homestake, 200 stamps; and Mineral Point, 100 stamps, making a total of 740 stamps dropping on ore. Cyanide No. 2 and the Mineral Point mill were started on February 23 of this month. The Pocahontas, the sixth mill, started on March 3, thus making the full 1000 stamps, and the mines and entire plant have thus resumed on a non-union basis.

SALT LAKE, UTAH.

Utah Metals.—Chino, Ray, and Gila Merger.—Chief Consolidated.—Jackling and the Guggenheims.

The Utah Metals tunnel will eventually be one of the longest and largest in Utah. From its portal in Middle canyon it has been widened for a distance of 2000 ft. for the purpose of placing a double track. It is 8 by 10 ft. for this distance, and will be driven through the mountain to the Carr Fork side of the range in Bingham, which will give it a length of 11,000 ft. The drain ditch is being enlarged below the tunnel so that it can carry from 1500 to 2000 gal. of water per minute. Heavier timbers are being installed, and a 35-lb. rail laid, with the track having a 24-in. gauge. A 6-in. galvanized vent-pipe and large compressor are being placed in position, while a large generator is to be installed for the power-plant, which is generated by the water flowing from the tunnel. After the face of the tunnel has been reached the management expects to make 400 ft. per month. The Jordan lime will be intersected within 3000 ft., at a depth of more than 2000 ft. from the surface. This deposit has been mined by the United States company in its territory, and $18,000,000 worth of silver-lead ore extracted. Some cross-cuts will be run from the tunnel-level, and the management expects to intercept at least six distinct fissure-veins.

It is generally understood that there will be a merger of the Chino, Ray Consolidated, and Gila copper properties within a short time. These are controlled by the same interests that own the Utah Copper. The Ray has 46,000,000 tons of copper ore, of an average thickness of 120 ft., and the general average throughout the mine is 2¼%. The Gila adjoins the Ray, and has more than 14,000,000 tons of copper ore averaging 2½%. The average thickness of this ore is greater than at the Ray. A 5000-ton reduction plant is now being installed on these properties, which will treat the ore from both mines. The widening of the railroad from Kelvin to Ray has been completed, and all the material for the mill will be on the ground within a short time. Chino has been said to have the thickest known orebodies in the world. At places the drill has penetrated a commercial grade of copper ore more than 500 ft. thick. Some of the orebodies in this property, which range from a few feet to 65 and 70 in thickness, contain an average grade of ore higher than 11%. In all there has been more than 14,000,000 tons of ore proved which averages almost 3% copper. The controlling interests in all of these estates have expressed a desire to place their holdings with one company, which will eliminate the expense of separate organization and management.

D. C. Jackling, vice-president and general manager of the Utah Copper, has just employed Louis S. Cates, formerly mine-manager of the Boston Consolidated, as assistant to R. C. Gemmel, who is first assistant to Mr. Jackling. Mr. Gemmel has recently inspected the Chino, Ray, and Gila properties, and Mr. Cates will next visit them and familiarize himself with the conditions. The object is said to be primarily for the purpose of relieving Mr. Jackling of so much of the field work, in order that he may devote more of his time to the Eastern end of the business. In this connection it is known that the Guggenheim interests desire to have all their mining and smelting business placed in the hands of a man with a large capacity for managing operations. They have expressed a desire to have Mr. Jackling take control of all their interests in this country, Mexico, and Alaska. He has not consented to do so while having all the business of the Jackling-MacNeill interests on hand, but it is understood that they have shown a disposition to increase his forces in the Utah territory in order that he could give his personal attention to a larger field.

BUTTE, MONTANA.

Labor Troubles Settled.—Litigation.—Guggenheims Buying Zinc.

The mines and smelters are once more running at about their normal capacity and the jurisdictional trouble between the Western Federation of Miners and the International Engineers has passed into history. For a time it looked as if the trouble might assume serious proportions. The Amalgamated Copper Co., through John D. Ryan, the president, made it plain when the trouble started that the company would stand by a contract which existed between the company and the miners. On the eve of a big mass-meeting Mr. Ryan published a lengthy review of the whole situation, and declared that the mines were going to be operated—if men were not in the city to do the work, they would be brought in. This settled the whole affair. The mass-meeting did little except talk, and in 24 hours the engineers began to apply for their jobs, and all talk of a sympathetic strike was over. Mr. Ryan in his statement declared that the company would live up absolutely to the terms of the contract with the miners so long as that organization could furnish men. The statement further declared that the company under no circumstances would discharge any man at present in its employ, and men leaving its employment might not expect to regain work. In concluding, the statement said: "The company proposes to run its mines, mills, and smelters and wishes to say to its employees who are members of other international unions that a careful and calm consideration should be given this entire controversy before any sympathetic walkout is ordered." Between the lines of the statement is the warning to all organizations that no further disputes or trouble will be tolerated, and it is believed this is intended to mean miners and smeltermen as well as all others.

A case of some interest in the mining world has been filed in the United States Court, the title being Levi M. Strong against the Berlin and North Butte Mining companies, W. D. Thornton, and A. J. Davis. Strong alleges that the defendants have 5000 shares of stock in the Berlin company which belong to him and he wants the court to issue an order giving him the stock. It appears Adam Gassert sold to Strong 10,000 shares of the stock, and in proceedings which finally were settled in the United States Supreme Court, Gassert recovered 5000 shares of the 10,000 originally sold to Strong. Now Strong alleges that after Gassert instituted the case against him to recover the stock, Thornton, in behalf of the North Butte Mining Co., entered into a contract with him whereby the mining company agreed to purchase from him the entire block of 10,000 shares, paying down $50,000 of the purchase price and agreeing to pay the remainder in $25,000 monthly installments. The agreement, it is stated, was that the stock was to be deposited with Andrew J. Davis and held until the full amount of the purchase price was paid. Strong asks that all contracts with the defendants be forfeited and terminated and that on his payment of $50,000 the 5000 shares of stock still in the hands of Andrew J. Davis be decreed to be his property. The Guggenheims are making an effort to secure interests in this State, and particularly in this district. S. D. Nicholson, Julius Rodman, and Mr. Plumb have been in the city for some time endeavoring to secure options on zinc properties especially. There is a report that they have secured an option on the Southern Cross mine for $850,000. The report is denied by the representative of the H. L. Frank estate, controlling a majority of the property. Mr. Plumb is known to have made a thorough inspection of the Southern Cross property.

General Mining News.

ALASKA.

An explosion of a powder magazine on the 1100-ft. level in the Alaska Mexican mine, on Douglas Island, near Juneau, March 3, resulted in the death of 29 men. The man in charge of the powder was killed and the cause of the accident has not been learned.——Ludwig Johnson, working on ground belonging to James Funchion, at Fairbanks, has found rich gravel near the upper end of No. 9 Below near the mouth of Deep creek. At this point it is 50 ft. to bedrock. Previously little pay-gravel had been found farther down Fairbanks creek than No. 5 Below.——Work is active along Chatanika and Cleary creeks. Max Altman has a considerable dump out on Cleary, and is increasing it. The four Riley shafts on No. 5 Below are down to bedrock. The Ballard is working, and the Berg dump is growing.——Gustard and Powell have dumps out on No. 11. On the Chatanika flats three young men, working No. 5, have made a discovery of pay-dirt. Alexander & Morrison's old ground is being worked by Mr. Webster. Sam Wise is opening up his ground, Watson is working five or six men, and Pearson has started work.

ARIZONA.

COCHISE COUNTY.

Production of copper at the Douglas smelters for the month of February was less than in January, but was at about the monthly average for the past six months. The exact figures are: Copper Queen, 8,940,000 lb.; Calumet & Arizona, 4,000,000 lb. The Copper Queen operates seven to

Map of Arizona.

eight furnaces, according to the quality of ore. In January nearly 10,000,000 lb. was produced. At the Calumet & Arizona four of the six furnaces are in blast and the average product for the past six months has been nearly 4,500,000 lb. Both smelters have had furnaces idle for two years. The Copper Queen has ten 500-ton furnaces, while the Calumet & Arizona has two 500-ton and four 300-ton furnaces. Two of the small furnaces are idle.——The entire output of ore from the Copper Queen mines is now being hoisted through one shaft, the Sacramento, and the big hoisting engine is handling the output easily. The ore is being hoisted at the rate of three tons per minute. Most of the ore is delivered to the Sacramento through the 400 and 1400-ft. levels, and the last connection with the Sacramento was made at the 1400-ft. from the Lowell. The power used for transporting the ore cars to the Sacramento is electric and the cars have roller-bearings. Some trouble has been experienced with the motors, but larger ones have been put in use on the 400 and 1400-ft. levels, and the company plans to build two locomotives especially adapted for the heavy work. A new compressor will be installed at the Copper Queen power house and will be ready for use about May 1.——The Calumet & Arizona Mining Co. has spent $1,000,000 in the development of outside properties. Development of rich sulphide ores in the lower levels of the Oliver shaft gives reasonable basis for hope that similar ores also will be found at greater depth in the Irish Mag shaft. Good ore is now being found 1000 ft. deeper than it was believed to have existed ten years ago.——At the Cole shaft of the Superior & Pittsburg company, the new orebody found on the 1000-ft. level has been thoroughly prospected and has proved to be a good sized body of rich oxide ore. The work on the bottom levels at the Cole continues to look encouraging. At the Hoatson, the 1300-ft. drift is being pushed through to the Briggs shaft. A new head-frame is being designed for this shaft. It will be ready in about four months. At the Junction shaft the 150-ft. level has been pushed toward the Hoatson at the rate of about nine feet per day for over a month. The sulphide orebody south of the shaft is practically proved now on three levels. At the Briggs shaft the 1200-ft. level is being cut, sinking being stopped while this is under way. As soon as the station is cut, sinking will be resumed.

GILA COUNTY.

(Special Correspondence).—At the Superior & Boston mine, stoping without the use of timbers has just been begun above the sixth level, in the western part of the workings. The drift being driven along the Iron Ledge fault on the sixth level, to reopen the Great Eastern lode, has advanced 100 ft. The sinking of the McGaw shaft, now in progress, has reached a point 52 ft. below the sixth level. On this level, a 1000-gal. Prescott pump is being installed. Both raises put up on the Great Eastern lode from the sixth level drift have passed continuously through 9% copper ore to the intermediate level 9 ft. above. J. D. Wanvig, the superintendent, is employing over 100 men. ——The drift north from the Telfair shaft of the Arizona-Michigan property, on the 500-ft. level, measures 488 ft., and is in quartzite, with practically no mineralization. The south cross-cut, 533 ft. long, has passed through 10 ft. of soft, faulted ground, containing a little iron, but no copper. It is expected that the directors, at a meeting at Houghton within a few days, will decide to have an air-compressor and machine-drills installed at the Telfair shaft. N. A. Nelson, the superintendent, is employing 20 men on development.——The Williams shaft of the National Mining Exploration Co. is being sunk in quartzite at a depth of 612 ft. Previously, diabase, limestone, quartzite, and black shale were sunk through by the shaft in the order named. H. W. Woodward is in charge.——The churn-drills on the property of the Miami Copper Co. are finding ore on the Captain claim, where the fourth hole is now being put down. During the last week in February, 911 ft. of driving, cross-cutting, and raising was completed on and above the 420-ft. level of the mine. The Miami Copper Co. is expending approximately $25,000 monthly in underground development.——The drift on which driving was recently begun, following the Black Hawk lode on the seventh level of the Arizona Commercial mine, has passed through 20 ft. of 7% copper ore, and since running out of this material, has been in ground running between 2½ and 3½% copper and containing, also, considerable iron. J. W. Bennie, the general manager, is visiting the property.——A churn-drill, already ordered for use on the Live Oak property, is expected to be on the ground and in operation by April 5. The average grade of ore opened by the four drifts and two raises now being driven has been 2½% for the past week. A report just made to the stockholders of the Live Oak Development Co. gives the following information: Receipts from founding of company to December 31, 1909, $192,240; disbursements, $163,746; balance of cash on hand, January 1, 1910, $28,494; net value

of tonnage developed to date, $1,875,000; tonnage blocked out monthly for past three months, 250,000 tons; past expenditures, from $3500 to $6000 a month. A call of $2 per share, payable April 1, 1910, will be made on Live Oak stock.

Globe, March 4.

GRAHAM COUNTY.

The Shannon-Arizona Railroad Company has completed its road from Clifton to Metcalf and is hauling ore over it. For the present there will be no passenger service.

MARICOPA COUNTY.

A decision has been rendered by Judge Edward Kent in the case entitled P. T. Hurley, plaintiff, United States of America, intervenor, against Charles F. Abbott and 4800 others, defendants, in a friendly suit instituted in 1905 for the purpose of ascertaining and the establishment by judicial decree, of the rights of all land owners to use water from the Salt river for irrigation. The suit was designed to wipe the slate of all complexities and prevent further litigation.——Ore assaying from $700 to $800 per ton is reported from the Vulture mine near Wickenburg. The Vulture is controlled by Canadian capitalists and is under the direction of W. Spencer Hutchinson. For the past two years the old mill only has been operated, 20 of the old stamps having been repaired and put in working order. A new mill with 20 stamps, each weighing 1500 lb., is being erected. The Vulture mine was discovered by Henry Wickenburg in the early '50s, and up to the time it was tied up by litigation, in the neighborhood of $20,000,000 was taken from it.

MOHAVE COUNTY.

The Bi-Metal mine, three miles south from Kingman, will erect a 40-stamp mill. The batteries will be similar to those of the Gold Road mill, but in other respects the plant will be different. The fine grinding will be done by Huntingtons instead of tube-mills, and since the ore is free-milling, cyanidation is unnecessary. There will be 32 ft. of plates below the stamps and 32 more below the Huntingtons. Pierce amalgamating traps will be used. The Bi-Metal, which has been under development for the past two years, has been thoroughly prospected by three shafts and numerous open-cuts. The result of this development is a body of ore estimated at 2,600,000 tons, assaying $4.16 in gold. The actual saving on all mill heads to date on plates has been about $3, or 72%. With the increased length of plates and better grinding the new mill is expected to make an extraction of about 84%, or about $3.50 per ton.——Several miles south of the Bi-Metal, in the same district, work is being started on the Gold Butte and Fay Bonanza properties. Lewis Lusk, of Spokane, one of the principal owners, has been examining the prospects. The entire bottom of a 40-ft. shaft on the Butte assays $8, while 10 in. of the vein on the Fay Bonanza runs $108. Samples taken across 20 ft. on the surface averaged $14.——The Rainbow mine has found good ore on the 225-ft. level, 175 ft. north from the main shaft, where two branches of the vein unite forming 4 ft. of good ore between well defined walls. Ten inches of the vein assay from $40 to $80 and the balance is milling ore. The breast is now midway between the south ore-shoot, which is developed to a depth of 240 ft., with ore blocked out for a length of 150 ft., and the Windsail shoot, from which the former owners shipped much high-grade ore.——The Pilgrim mine, 12 miles west from Chloride, owned by William O'Day, is being examined by engineers representing Spurr & Cox, of New York. The Pilgrim is in the same range as the Gold Road mine and has ore of a similar character. It averages about $8 in free-milling gold.——The Venture company, of Duluth, which has been in active operation at Globe as the Cactus Development Co., for some time, is the latest of the new companies to enter Mohave county. John B. Hamilton and Frank Meyers, representing the Easterners, are sampling a number of properties in the different districts of the county, and have already bonded the Oneida group in Lorena Flats, belonging to O. D. Gaddis. The Oneida properties adjoin Stockton Hill mines, on a number of which the United States Smelting, Refining & Mining Co. is extensively developing.

PIMA COUNTY.

Objecting to an order commanding all the employees of the company to trade at the company's store and board at the company's boarding house, employees of the Chesterfield Copper Co. have walked out on a general strike. The Chesterfield mines are situated about six miles from Twin Buttes. They comprise 15 properties adjoining the Esperanza claims. C. T. Roberts was appointed general manager of the properties recently. The company employs between 10 and 15 men.——An important discovery was recently made in the Esperanza mine on the 300-ft. level. The entire face of the drift is in high-grade silver and lead ore containing also gold and copper. A car shipment returned a net profit of over $1800. The Chesterfield and Esperanza are contiguous properties and can be well managed under one head, that being the present intention of the two companies. This plan will undoubtedly prove advantageous to both. Three shifts have been run on the Chesterfield in good ore. The main working shaft is now down over 300 feet.

YAVAPAI COUNTY.

The Yavapai Bullion Mining Co., owning placers in the Copper Basin district, is planning to build a three-mile pipe-line. The survey has been completed, and the pipe will arrive in a short time. W. S. Bradford, the engineer in charge, states that tests of the ground have been made at many points. The company has acquired title to 1120 claims.

YUMA COUNTY.

The railroad from Bouse to Swansea has been finished and work on the smelter of the Clara Consolidated is being rushed to completion.

CALIFORNIA.

CALAVERAS COUNTY.

The Calaveras Copper Co. has taken over from the Union Copper Co. the famous old copper mines at Copperopolis. The present 300-ton concentrator will be doubled, and a blast-furnace, of 250 tons capacity, will be installed. In addition to the reverberatory furnace now in the plant, this will give a total daily capacity of 400 tons. Two stands of convertors will also be provided. A supply of ore sufficient for two years, said to average 4% copper, is available. The new company has a capitalization of $1,000,000, divided into $5 shares. Of this amount $600,000 are issued and pooled, and $400,000 remain in the treasury. Charles M. Hayden is president, J. Newton Cole is secretary-treasurer, and J. H. Trerise is manager. The Eastern agent is Theodore Lurman, 87 Ames Bdg., Boston, Massachusetts. It is expected to begin operations in the autumn.

LOS ANGELES COUNTY.

Delegates and visitors in Los Angeles during convention week of the American Mining Congress, from September 26 to October 1, will be given the opportunity of inspecting mining and oil machinery of all kinds, models of some of the famous mines of the Southwest, and a comprehensive collection of ores and oil samples. The Sierra Madre Club, which has charge of local arrangements, has decided on such an exposition. A central down-town location will be secured and a small admission fee charged to cover expenses. The Chamber of Mines will be asked to take charge of the mineral collection. Preliminary plans for the Congress are gradually taking shape and answers to requests for co-operation from outside points are coming in. E. D. Johnston, president of the San Diego Chamber of Mines, has been elected to represent that organization on the advisory committee.——Pending legislation to regulate the issuance of assay certificates, the committee of the Chamber of Mines having this matter in charge has been authorized to take immediate steps to investigate the methods of assayers in Los Angeles and vicinity, claiming 'secret porcesses'. The Chamber of Mines also passed resolutions supplementing its previous recommendations as to the necessity for the creation of a Bureau of Mines, and also instructed the secretary to urge upon the California Representatives and members of the House Committee on Mines and Mining the passage of Mr. Flint's bill providing for

the establishment and maintenance of a Federal assay office in Los Angeles.

NEVADA COUNTY.

Splendid progress is being made in erecting the great head-frame at the Mountaineer mine. As soon as it is finished the work of sinking from the surface to connect with the lower levels of the partly completed vertical shaft will begin. The Mountaineer is in good ore and will be equipped to sink over 2000 ft. vertically.——The 10-stamp mill at the Pittsburg mine is running again, and fine ore from the drifts on the 1000-ft. level is being stoped.——At a depth of 400 ft. the Nassau shaft has struck the old workings of the Eureka mine. The Nassau was formerly the Dana. It is situated near the Idaho-Maryland and the Golden Gate.

SHASTA COUNTY.

(Special Correspondence).—The Mammoth Copper Co. has resumed work on the bag-house with 60 men. Steel work and equipment for the plant is on the way from the East. The management hopes to have the plant completed in June.——The Balaklala Copper. Co. is experimenting with the Cottrell fume-controlling device. F. G. Cottrell is in charge of the experimental work.——The remodeled furnace at the Bully Hill plant is in commission. The new jackets are of electric-welded steel, in place of the riveted point designs formerly in use. The improved furnace was designed by the engineering staff of the company and built by the Allis-Chalmers Co. A Kilker matte-dumping device has also been installed.——The working force at the Evening Star has been increased and arrangements are under way for a markedly enlarged production. The property was recently purchased by German capitalists.——The Midas is pushing developments in the lower levels. The monthly production approximates $50,000.——The Milkmaid, under new management, is working a large force of men and maintaining an excellent output. New machinery is being installed.——The Black Tom Mining Co. has been granted 30 days in which to meet the indebtedness against the Niagara mine, in the French Gulch section. Judgment against the company for $3200 was recently given in the Superior Court.——The second payment on the $115,000 purchase price of the Evening Star mine was made at Whitehouse February 26. There is a 5-ft. vein of good ore in the shaft. The working force has been doubled since the new management took hold less than a month ago.

Redding, March 5.

SIERRA COUNTY.

A discovery of rich ore was made at the Standard mine, in Sailor ravine, last week by Jason Frye and Robert Blevins. The find was made in the lowest level in the lower adit, some 180 ft. from the surface. The vein will average over 2 ft. in width. Two shots blasted down 600 lb. of sulphides and several hundred pounds of rich specimen rock. A conservative estimate places the amount obtained so far at $5000.——J. S. Johnson, general superintendent and president of the Neocene Placer Mining Co., which has the largest hydraulic mine in the world at Scales, states that work will soon be resumed. The mine is near the Plumas county line, and has been idle for many years on account of the anti-débris legislation. Since the Neocene company purchased the property last season, extensive improvements have been made by installing a large concrete dam to impound the tailings. Cuts and adits have been run into the deep ground to enable the monitors to pipe the gravel, and thousands of feet of flumes have been put in to carry the débris to the dam.

SISKIYOU COUNTY.

Joe Davidson and Ben Hall made a rich discovery in their claim in Portuguese gulch March 1. They found a vein about a foot wide, from which they have taken out a quantity of specimen quartz.

TRINITY COUNTY.

(Special Correspondence).—The Poverty-Slide hydraulic mine, at Trinity Center, has begun sluicing and the wash on Coffee creek will start up on March 10.——The outstanding debts of the Bonanza King are being paid up by the California Trust Savings Bank and the mine will start as soon as the weather permits.——The Headlight is excavating for the foundation of its 40-stamp mill.——The Strode mine, one mile northeast of Carrville, has been sold to New York and Los Angeles capitalists, the deal being negotiated by W. H. Cleary of the latter city, one of the purchasers. The price is said to be $12,000, and possession will be given on March 15. The new company will extend the lower tunnel 3000 ft., enlarge the milling plant, and develop a large low-grade free-milling vein hitherto untouched.

Carrville, March 1.

The Trinity River Dredging Co., a Chico corporation, has made its final payment on 900 acres of dredging ground along the river above Lewiston. The dredge is to be built in the spring as soon as material can be hauled to the ground. The company has bought the water-right, pipeline, and bridge formerly owned by the Fairview Mining Co., which was abandoned two years ago. The 1000 inches of water will be used to develop power for operating a sawmill that is to cut the lumber for building the dredge, and will later operate the dredge itself. The Fairview company spent thousands of dollars on the pipe-line and suspension bridge across Stuart's Fork.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The engine room on the adit-level of the East Griffith mine is being retimbered and enlarged. Electric power and machine-drills are to be installed.——The Grand Trunk adit has been driven 160 ft., and for the last 15 ft. a streak of $55 gold-silver ore, that is from 4 to 6 in. wide, has been followed.——Shipments are to be started from the Homestake property, on Lincoln mountain, during the coming month. A streak of ore is showing in the heading that is from 10 to 16 in. wide and worth 23 oz. in gold per ton.

Georgetown, March 3.

(Special Correspondence).—At the Princess Alice property at Alice, large bodies of mill ore are exposed and the 50-ton mill will be started as soon as water is available.——Max Boehmer, president of the Druid Hill Gold Mining Co., was in town last week to look over the holdings he represents. He stated that the Adduddel lateral in the Newhouse tunnel will be extended 400 ft., and a station is made from which a raise will be driven 1500 feet.

Idaho Springs, March 4.

GILPIN COUNTY.

(Special Correspondence).—A 6-in. streak of ore has been uncovered on the 800-ft. level of the Pittsburg mine that assays 130.41 oz. gold and 17.6 oz. silver per ton, with 4.8% copper.——The shaft on the Ready Cash mine is to be sunk another 100 ft., making the total depth 250. A pool of local business men is financing the work. The vein is an extension of the Eureka, one of the high-grade producers of this district.——At the S. S. M. property, in the Wide Awake district, a streak of ore has just been found 100 ft. from the entrance of the adit that is worth 208.6 oz. in gold per ton.——It is reported that the Adduddel and Frontenac properties have been merged by H. P. Lowe. English capital has been interested.——The Champion group is to operate under lease.

Central City, March 4.

LAKE COUNTY.

Leadville has had heavy snow but improvements continue to be made. The head-frame and other surface improvements recently installed on the Colonel Sellers property have been completed and are now being used. Ore is hoisted regularly. Sinking the new Colonel Sellers shaft is progressing. It is likely that the Belgian and Frenchman properties, on Iron hill, will soon be operated. These claims have never been fully developed. They contain 14 acres of patented ground on the summit and east slope of Iron hill, and directly in the trend of the largest ore-shoot in the Leadville district—the great Iron-Silver ore-shoot, which has been developed from a point 2500 ft. west of the property line up to the Belgian-Frenchman claims. Other mines east of these claims have taken up the same ore-shoot, indicating that the mineral passes through this prop-

erty. The vein on the Iron-Silver property averages 200 ft. in width and 60 ft. in thickness. At a depth of 440 ft. from the surface in the Belgian property a body of high-grade lead ore has been discovered, which, during the former operations, produced about $12,000 worth of ore. Another body bearing silver and lead with fair values in gold has produced nearly $60,000 worth of mineral.

TELLER COUNTY.

Stratton Estate mines, near the American Eagles, are doing well. Returns have been received by Geiglein & Sons, operating on block 239 from the initial shipment. The ore returned $50 per ton. It was mined in sinking the shaft, now down 30 ft. At the surface lessees found rich float and commenced saving ore before out of the wash.——The same vein is under development by Cotton & Brown, lessees, on block 238. The shaft is down about 20 ft., and between 20 and 25 tons of ore is lying on an ore-plat awaiting shipment.——Tim Moynahan is breaking ore, worth about $25 per ton, in a new shaft sunk by him on block 251, now down about 30 ft.——The February output of the Strong mine, on Battle mountain, is placed at 47 cars of ore, ranging in value from $40 to $225 per ton.——Operations have been resumed on block 20, of the Mary McKinney Mining Co.'s Gold Hill estate—originally owned by the Anaconda Gold Mining Co. The lease on this ground is held by J. H. White and associates, of Colorado Springs. A. J. Bunch has been placed in charge as superintendent, and the lease is to be operated through the Grace Greenwood shaft.——At the E. Porter Gold King mine, on Gold hill, work was begun March 1 by John Sharpe for the owner, though certain ground will be reserved for leasing purposes.——The initial shipment for the Rexall Gold Mining Co., owning and operating the Spicer mine and territory adjacent thereto, was loaded out from the main shaft last week. The shipment, made up of coarse quartz and screenings, about 27 tons in all, is estimated at about 2 oz. gold per ton. The ore was taken out in a drift, at the 900-ft. level of the Spicer shaft, on the main vein, at its junction with a new lead, now known as the Grace vein. The company will shortly start construction work on a modern and up-to-date mill.

NEVADA.

STOREY COUNTY.

It was formally announced this week that plans for organizing a great holding company to control and operate

Ward Shaft, Centre of the New Work.

the Comstock mines had been completed. While the mere announcement did not of itself create much of a surprise, for there have been rumors of its formation for several weeks, the names of those back of the plan caused a decided surprise. The committee in charge represents a majority of the shareholders of the Comstock mines, including the Alta, Alpha, Andes, Belcher, Bullion, Best and Belcher, Consolidated-Virginia, Crown Point, Chollar, Consolidated Imperial, Challenge, Caledonia, Confidence, Exchequer, Gould and Curry, Hale and Norcross, Justice, Julia, Kentuck, Lady Washington, Mexican, New York, Ophir, Overman, Potosi, Savage, Sierra Nevada, Segregated Belcher, Union Consolidated, Utah, and Yellow Jacket. It includes Franklin Leonard, Jr., chairman, treasurer of the Comstock Tunnel Co.; Adolph Lewisohn, president General Development Co., New York; Ernst Thalmann, of Ladenburg, Thalmann & Co., New York; A. L. Scheuer, of Probst, Wetzlar & Co., New York; Charles A. Ellis, Boston; B. F. Shaw, of Shaw Brothers, San Francisco; W. C. Ralston, San Francisco; James McNab, of McNab & Smith, San Francisco; and J. Parke Channing, of New York. The formation of the holding company not only enables the development of new orebodies, but it simplifies the management of the various corporations. In place of stock jobbery and inharmonious action, the work of development will proceed under one general head, and it will be performed in the most economical manner. It is primarily a combination of vast capital for exploiting the lower levels of the Comstock Lode, in the belief that the unexplored ground contains rich orebodies, which only remain to be developed to prove their great extent and richness. The capital stock of the new holding corporation will be probably between $6,000,000 and $10,000,000. It will be underwritten and amply secured. The individual companies will continue to exist, each with its own officers and boards of directors; but the control of their affairs and the actual work of development at the mines will be vested in the holding company. In the working of the mines the direction of affairs will be under the control of Mr. Channing as consulting engineer.

NYE COUNTY.

(Special Correspondence).—The first clean-up of the Tonopah Extension mill resulted in seven bars of bullion, valued at approximately $7000. The company is treating the ore stored on the dumps.——Tonopah, of Nevada, is maintaining approximate shipments of 3350 tons of ore per week, mainly from the Red Plume, Silver Top, and Valley View veins.——The orebody found on the 1100-ft. level of the Belmont has been opened for 250 ft. west of the fault, and shows a width of from 8 to 16 ft. With the exception of a small streak of waste in its centre, the vein is of milling grade. On the 1150-ft. level there is 3 ft. of milling ore.——The working force at the Tonopah Liberty has been increased and considerable ore has been opened. T. S. Carrahan, the manager, expects that a milling plant will be erected this summer.——Robert T. Christian has been placed in charge of operations for the Nevada Copper Co., operating east of Sodaville.——The north cross-cut from the 765-ft. level of the Montana Tonopah has entered the lode porphyry at a point 2700 ft. from the shaft. The porphyry is outside the proved ore-zone and was found after driving through a belt of rhyolite.——A. C. Elsen has resigned from the directorate of the Mayflower Con., and the new board of directors will at once take charge of the property. The mine, mill, and estate have been leased to the Mayflower Leasing Co. for a term of four years, upon a basis of 50% royalty of the net profits of the leasing company. Mayflower stockholders are given the preference in subscribing for stock in the leasing company. This has been incorporated for 100,000 shares, par value, $1. Stockholders will be offered 40,000 shares.

Tonopah, March 3.

WASHINGTON.

FERRY COUNTY.

Reports submitted at the annual meeting of the New Republic Mining Co. show a past production of $100,000. Much dead work has been necessary to put the mine in shape. New machinery has been installed and ore broken or in transit is considered of sufficient value to cover the present indebtedness of $6000. R. J. Howard, W. B. Parker, F. B. Babcock, M. J. Burns, John De Young, F. Kingbaum, A. Babcock, O. B. Hollis, and John Fullenweider were elected directors.

OKANOGAN COUNTY.

The Lucky Knock Mining Co. is planning to erect a 40-ton smelter for treating antimony ore. A recent shipment of 19 tons was made through Ledoux & Co., in New York. The orebody has been penetrated for 14 feet.

KITTITAS COUNTY.

An avalanche is reported to have wiped out 12 of the 16 buildings at the Skookum mine, four miles from Mount Stuart. One man was killed.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. S. Noyes has returned from Oregon.

R. V. Neily is at Prieta, Chihuahua, Mexico.

Bernard MacDonald is now at Parral, Chihuahua, Mexico.

Henry Bollweg is at the Washington mine, Cumpas, Sonora.

J. H. Trerise was in San Francisco. He has returned to Copperopoiis, California.

A. E. Drucker will sail from San Francisco for Korea on the *Tenyo Maru* March 15.

H. W. Du Bois passed through San Francisco on his way from Arizona to British Columbia.

Joseph Donnelly is now general mine superintendent for the Goldfield Consolidated Mines Co., at Goldfield, Nevada.

Hallet R. Robbins has been appointed managing engineer for the Victory Mining Co. at the Ironsides gold mine near Boise, Idaho.

Hal. McLaughlin has been appointed general manager for the Central Chili Copper Co.'s smelter and mines in the province of Coquimbo, Chile.

Robert H. Richards read papers on 'Developments in Ore Dressing Machinery' at the Pittsburg meeting of the American Institute of Mining Engineers and the Toronto meeting of the Canadian Mining Institute.

Dwight J. Lawton, formerly connected with the Bourne syndicate, and later expert in the United States General Land Office, has resigned to take charge of the old Plumas Eureka mine in Plumas county, California, for New York capitalists.

Societies and Universities.

The American Electrochemical Society will hold its next meeting at Pittsburg, Aprii 28, 29, and 30.

Cornell University has this year more than 5000 students, of which number 1724 are registered in engineering.

The Geological Society of London this year awarded the Wollaston medai to W. B. Scott, and the Murchison medal to A. P. Coleman.

The University of Wisconsin has established two engineering fellowships and is equipping a metallurgical laboratory.

Dividends.

The Round Mountain Mining Co. will pay a dividend of 4c. per share, May 25, to stockholders of record March 20.

Review of February Copper.

By Misha E. Appelbaum.*

From Febrnary 1 to 24 the copper business was at a standstill, and the market gradually sagged from 13⅞ to 13½c. delivered in 30 days, when sales to domestic consumers, aggregating about 30,000,000 lb. were made. These sales had little effect on the market, but at the end of the month, when it was found that for the first time in over a year the visible supply in Europe showed a decrease, in addition to the 43,000,000 lb. decrease in this country in January, most of the selling pressure disappeared, and producers confidently held for higher prices. There is no doubt that if the copper which is being shipped to Europe is going into the hands of consumers, and if the visible supply on this side continues to decrease, higher metal prices will be recorded. In spite of the general slackening in business, the metal manufacturers are still working full force, and as I do not share the opinion, prevailing in some quarters, that the country is facing a business reaction, I confidently expect the metal to reach higher levels, with but very slight depressions.

*President of the New York Metal Selling Company.

COMPANY REPORTS.

BRITISH COLUMBIA COPPER CO., LTD.

The report of this company, operating mines and a smelter, which also does custom work, at Greenwood, B. C., shows matters to be in satisfactory condition despite loss of three months time, due to a strike at the Crows' Nest Pass coal mines. The company now owns 132,556 shares of the capital stock of the New Dominion Copper Co., Ltd., corresponding to 53% of the total. During the year the smelter handled 373,336 tons made up of 3949 of converter slag, 6964 of custom ore, and 362,423 of ore from the company's mines. Of this latter the Mother Lode yielded 337,089, the Oro Denoro, 13,384, and the Napoleon 11,950. The yield was, fine copper, 6,325,000 lb.; gold, 18,244 oz.; silver, 64,234 oz. The yield in copper per ton of the company ore was 17.7 lb., and of gold and silver $1.03. The price realized for the copper is given as 13.08c. and the cost, after crediting the value of the gold and silver, 9.829c. The cost per ton of ore, including all charges from ore in place to sale of metals, was $2.68, according to J. E. McAllister, general manager.

RIO PLATA MINING CO.

This company operates mines in Chihuahua, Mexico, and maintains executive offices at New York. The company sends to its stockholders monthly reports, of which that for January 1910 is abstracted below, the figures being given in U. S. currency. Net returns on shipments, $14,030; stamp-mill, operated in part all the month, equal to 29.93 days at full capacity, crushed 1706 tons of dry ore, containing 93,872 oz. silver, gross, and produced 36 tons concentrate; cyanide plant, operated to about three-fifths of its capacity, treated 1276 tons of tailing, containing 38,142 oz. silver, gross; tailing stored in pond during month contained 19,695 oz. silver; expended on mine development, $1400; recovered in concentrate, 36,035 oz. silver; recovered in shipping ore, 2676 oz. silver; recovered in bullion (by cyanide), 32,453 oz. silver; total silver recovered, 71,164 oz.; value of silver recovered, $33,510; operating expenses, 13,463; operating profit (exclusive of stored tailing), $20,046.

In the second annual report covering the year ended November 30, 1909, the president, H. W. Miller, summarizes important developments as including: (1) The paying off in full, in the month of May, of all indebtedness on the mine. Funds for this were derived mainly from the sales of the product of the mine, and disbursements for the same amounted to $109,013. (2) Completing the plant and improvements as follows: cyanide plant; auxiliary steam-power plant; increased water-power plant; two tube-mills; electric-power plant; and other necessary equipment. Total disbursements for these purposes during the year amounted to $105,607.

The general manager, D. W. Shanks, states that there was mined during the year 14,580 tons of ore, averaging 63.8 oz. of silver, containing 930,638 oz. from which was sorted 35.1 tons shipping ore, assaying 1135.3 oz., containing 39,851 oz., and sent to the mill 14,545 tons averaging 61.21 oz. The cost of mining was $1.89 per ton; this covering labor, timbers, explosives, hoisting, and tramming. Milling operations for the year are summarized as follows: Delivered to the mill, 14,545 tons of ore; average assay value, 61.21 oz. of silver; total contents, 890,787 oz. of silver; recovered in concentrate, 360,776 oz. of silver; tailing from concentrate, 14,212 tons; contents, 530,011 oz. of silver; average value, 37.3 oz. per ton; treated by cyanide, 2143 tons tailing; contents, 70,031 oz. of silver; recovered, 61,361 oz. of silver; extraction, 87.6%; leaving for storage, 12,069 tons tailing; contents, 459,980 oz. of silver; average value, 38.1 oz. per ton; total tailing stored in pond to December 1, 1909, 26,685 tons; contents, 1,105,098 oz. of silver; average value, 41.03 oz. per ton; cost per ounce of silver recovered, 27.5c.; cost per ton of ore handled, $8.181.

It will be noted that the recovery by concentration for the year ended November 30, 1909, was 40.4% of the total value, while for the fiscal year 1908 it was 52.8%. This is accounted for by the appearance in the upper level of barium sulphate, the specific gravity of which is so nearly that of silver sulphide as to make it impossible to exclude a considerable portion of it from the concentrate. While the recovery was thus reduced, the contents of the tailing, from practically the same tonnage as that milled in 1908, was nearly the same. This lower extraction operated to increase the cost per ounce, but if the charges against cyaniding included in 1909, but not incurred in 1908, be deducted, the cost per ton remains virtually the same—$7.11 in 1908 and $7.18 in 1909. Barium sulphate does not affect the extraction in cyaniding, so that values not recovered by by concentration are saved later in the cyanide plant. In designing the plant 85% was given as the probable recovery in the cyanide plant; the average has been 87.6, and for November was 90 per cent.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

A PRIMER ON EXPLOSIVES FOR COAL MINERS. By Charles E. Munroe and Clarence Hall. Bulletin 423, United States Geological Survey. Washington, D. C., 1909.

Although specifically addressed to coal miners, this little book is of almost equal application to blasting in metal mines and in open rock-excavation. Furthermore, it is well to state that the senior author of the primer may be called America's Berthelot, the greatest authority on explosives in this country, than whom no man can speak with greater understanding of these treacherous materials, both on the theoretical and practical side. The work is extremely elementary, free from technicalities, and addressed in plain language to the plain men who are concerned in the actual use of these assistants of the miner and quarryman. Therefore the treatise opens with an account of combustion, leading logically to the explanation of this process when sustained by oxygen liberated in contact with certain substances, independently of aid from atmospheric oxygen, which is the principle of explosive mixtures. Incidentally a classification of explosives is attempted, but the line of demarkation is not sharply established. Mr. Munroe divides them into low and high explosives—perhaps the most useful classification—but the attempt to limit these classes by composition fails as soon as examination of the modifications of 'high' explosives is made. The saltpetre explosives, which undergo merely rapid combustion, as contrasted with the nitroglycerin class, whose normal habit of dissociation is practically instantaneous detonation, do not comprise all 'low' explosives by any means, as he himself shows later on. The tendency has been quite distinctly to depart from saltpetre explosives in an effort to secure slow-acting rending effects by means of modified nitroglycerin or nitro-cotton mixtures, together with various nitro-substitution compounds. The description of the latter type of explosive seems to us to have been rather too briefly given in relation to its growing importance. While these nitrated coal-tar products are, as stated in this primer, generally susceptible to injurious change from absorption of moisture, some of them are remarkably water-proof, and may be used to envelop and protect the more hygroscopic compounds, producing an explosive possessed of resistance to water, either in storage or in wet blast-holes, equal to that of the gelatin dynamites. Their lessened sensitiveness to shock, moreover, commends them on the side of safety. It is quite noticeable that the authors refrain from expression of opinion concerning the merits of different makes of explosives, contenting themselves with statements of proved and well known facts, which is as it should be in a Government publication that must avoid anything likely to work to the detriment of the manufacturer, but it appears in many cases that more details might have properly have been given. The subject of 'chlorate powders' is dismissed rather summarily, with a warning as to their sensitiveness, but with rather too brief an account of 'stabilizers' through which it is hoped to produce safe mixtures capable of being locally manufactured, thus avoiding both the peril and the high cost of transportation. One of the chief advantages of such a primer as this lies in its explanation of the nature and behavior of explosives. Mere rules for safety are not

enough; the user may forget the rule when the reason for it is unknown, but if he comprehends the nature of the substance with which he deals he can be his own guide to rational use. In this respect the book as a whole is excellent, but the case mentioned above, in connection with chlorate of potash powders, constitutes an omission, all the more serious because these are being brought to the attention of people in this country as a result of the partial success obtained with them in Europe within the last few years.

The instructions regarding the handling and care of explosives are excellent, but we regret that a more explicit description of the phenomena of freezing of the nitroglycerin mixtures was not given, nor any caution as to the conditions under which even frozen dynamites are dangerous. A note of warning is sounded, which cannot be too strenuously insisted upon, regarding the powders in which the freezing point is lowered by the admixture of ammonium nitrate and other substances. Storage in the dark is counselled, which is well. Although explosives are made with a degree of care seen in few articles of manufacture, so that spontaneous decomposition is extremely rare nowadays, nevertheless the action of light promotes chemical change, disturbing the delicately balanced chemical equilibrium of the mixture. An explosive is like a glass ball poised on the top of a spire; it is in equilibrium, but unstable; a drop of moisture too much on one side suffices to precipitate it through a violently destructive process to a new but permanent equilibrium. Commendation is due for the emphasis laid upon the need of dry-storage. In calling attention to the fact that excessive dryness also has its disadvantages it might have been well to inveigh against the common practice of storing explosives in tunnels. Even in the dryer parts of the desert regions of the Southwest a moisture-content of from 7 to 12% is found in the rocks at a short distance from the surface, and this leads to a moist magazine as the mouth of the tunnel is tightly closed by a door.

It is because of our admiration for this work that we are disposed to examine it so minutely. It is a treatise that should be in the hands of every man who uses explosives. It is the only work now in print, suitable for the non-technical man, and it is authoritative and able. We are merely pointing out what seem to us omissions, caused evidently by the desire to keep within narrow limits of space. The report is too condensed. We think the Geological Survey might well have given the authors freer rein while the work was in the doing. Our only distinct difference of opinion with the teachings of the book is in regard to storage magazines. We cannot see by what process of reasoning brick or stone structures can be recommended for this purpose. They absorb and retain moisture to a greater extent than surfaced and painted weather-boarding; they become hotter, and render ventilation more difficult in a hot country; and, if an explosion occurs, every brick and stone in the structure becomes a dangerous missile, with a destructive range dependent upon the quantity of explosive in storage at the time. A frame magazine with double hollow walls, one filled with broken glass and one with dry sand, is both vermin and bullet-proof, and a sand or earth-wall, properly maintained as a surrounding barrier, serves both for fire-protection and as a deflector to circumscribe the area of danger in case of an explosion, while the magazine itself is merely reduced to splinters by it.

We have not touched upon the questions of fuse, squibs, and detonators, electric and fuse-firing of charges, and the preparation of primers, which are all adequately discussed; nor have we been able to review the special pages devoted to the use of explosives in gassy mines. The latter is extensively presented, together with a description of the admirable work which has been going on for two years under the guidance of J. A. Holmes at the experimental testing laboratory of the U. S. Geological Survey at Pittsburg, Pennsylvania. The conditions under which explosives ignite dangerous mixtures of coal-dust or gas, and air, are set forth, and the methods employed at the testing works for determining the safety of blasting powders. This is accompanied by a list of the permitted explosives.

THE ELEMENTS OF MACHINE DESIGN. Part I. By W. Cathorne Unwin. New edition. Pp. 532, ill., index. Longmans, Green & Co., New York, 1909. Price $2.50.

For thirty-three years Unwin's treatise on machine design has been a standard, familiar to engineering students, and to practical workers in the shops, throughout the world. While not elaborately illustrated, it gives a clear exposition of principles that makes the way easy to the solution of the problems arising in everyday work. The new edition is in fact a new book in appearance and in content. It has been wholly re-written, greatly enlarged, and contains many new and useful features.

GEOLOGY AND WATER RESOURCES OF THE NORTHERN PORTION OF THE BLACK HILLS AND ADJACENT REGIONS IN SOUTH DAKOTA AND WYOMING. By N. H. Darton. U. S. Geol. Surv. Prof. Pap. 65. Pp. 105, ill., maps, index. Washington, 1909.

WINTER SCHOOL OF MINES—ANNOUNCEMENT. Quart. Bull. State College, Vol. 2, No. 3. Pp. 10. Pullman, Washington, 1909.

A brief announcement of short courses for the benefit of coal and metal miners given January 4 to March 30.

MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN THE WESTERN STATES AND TERRITORIES IN 1908. By A. H. Brooks, C. N. Gerry, V. C. Heikes, C. W. Henderson, H. D. McCaskey, Chester Naramore, and C. G. Yale. U. S. Geol. Surv., Min. Res. U. S. Pp. 314. Washington, 1910.

INVESTIGATIONS OF COAL FIELDS IN INDIANA, NORTH DAKOTA, AND MONTANA IN 1908. By G. H. Ashley, C. D. Smith, R. W. Richards, L. J. Pepperberg, and C. H. Wegemann. U. S. Geol. Surv., Bull. 381-A. Pp. 110, maps. Washington, 1909.

QUALITY OF SURFACE WATERS IN THE UNITED STATES. Part 1. Analyses of Waters East of the One Hundredth Meridian. By R. B. Dole. U. S. Geol. Surv., Water-Supply Paper, 236. Pp. 123. Washington, 1909.

GEOLOGY OF THE WHANGAROA SUB-DIVISION, HOKIANGA DIVISION. By J. M. Bell and E. de C. Clarke. New Zealand Geol. Surv. Bull. 8, N. S. Pp. 115, ill., maps, index. Wellington, 1909.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

E. S. A., San Antonio, Texas: A specimen of calc-tufa.

J. A. F., West Point, California: A specimen of black tourmaline.

H. O. Y., Bowman, California: No. 1, pyrrhotite in hornstone; No. 2, massive tremolite.

H. W., Burrough, California: Quartz with sulphide of iron.

R. W., Winnemucca, Nevada: A metamorphic rock with cubes of pyrite; the geological age cannot be determined from the specimen.

J. P. L., Battle Mountain, Nevada: The brown sulphide is pyrrhotite and the greasy brownish silicate is garnet; some chalcopyrite is present.

J. P. C., Goldfield, Nevada: No. 1, altered rhyolite; No. 2, rhyolite with cubes of pyrite; No. 3, altered rhyolite; No. 4, volcanic tuff. The base of these specimens has altered to clay.

J. S., Bearmouth, Montana: No. 1, tetrahedrite in barite with a little secondary malachite and azurite; No. 2, tetrahedrite and chrysocolla. The green color is due to copper.

O. S. G., Porterville, California: No. 1, yellowish green serpentine; No. 2, oxidized pyrite.

EDITORIAL.

NIGHT LETTERS by telegraph is an innovation which will be appreciated by the public. Fifty-word messages (in plain English only) will henceforth be transmitted at night for the same sum as ten-word messages at other hours.

THE PRESIDENT of the Philadelphia Rapid Transit Company finally consented to meet the president of the Amalgamated Association of Street & Electric Railway Employees. So long as the strike merely entailed inconvenience to the public, occasional rioting, and some loss of life, the company refused to arbitrate. It is said that its change of attitude was due to the refusal of members of the Stock Exchange longer to support the stock of the company. Such incidents make more anarchists than dozens of Emma Goldmans.

ANNOUNCEMENT of the isolation of a considerable quantity of the rare metal polonium, by that gifted experimenter Mme. Curie, is of supreme interest for the scientific world. Polonium is even more energetically radio-active than radium, and its transformation occurs at an enormously rapid rate. The study of its transmutation offers an opportunity to work out important physico-chemical laws. The polonium obtained by Mme. Curie was extracted from pitch-blende, and it is stated that in a period of 140 days one half of the total quantity isolated disappeared as a result of its transmutation into other substances.

WARFARE seems to be the lot of the Anaconda Copper Company as long as it persists in performing the work of smelting copper, for which it was organized. The old smoke-suit has been granted a re-hearing, and now comes Uncle Sam with a brand-new Pandora's box of troubles, threatening injunction to save the National Forests. Dispatches from Washington mention the possibility of solving the smoke problem by making the fume into sulphuric acid to be used in converting raw phosphate to the soluble form. This is all possible, but it would involve an enormous outlay of capital and continuing losses in operation. Incidentally, Uncle Sam himself has withdrawn all phosphate land from entry, temporarily at least, discouraging such an enterprise.

CYANIDATION of sulphides is a matter of such great importance that the article on the treatment of concentrate by Mr. A. E. Drucker, published in this issue, will attract wide attention. The statements of Mr. Drucker acquire the greater weight because the method which he has finally adopted for installation at the works of the Oriental Consolidated

Mining Company in Korea is the fruit of lengthy experiments, and of observation of cyanide practice in all parts of the world. Mr. Drucker has recently studied gold milling in Australia, India, South Africa, and the United States. This should equip him for superior electicism. The result is shown in the extraction of 92 per cent of the precious metal from the concentrate at a cost of less than $3 per ton of original ore milled, including all-sliming and air-agitation.

WHEN the Osceola mine in the Lake Superior copper district was turned over to the Calumet & Hecla Mining Company by virtue of the decision permitting the latter to own and vote stock in the former concern, the market quotations of Osceola shares immediately rose. This showed in an unmistakable manner the preference of the public for Calumet & Hecla management. While operated as a Bigelow property good results were obtained, and in 1906 a dividend of $10 per share was paid, due in part to the phenomenal average price of 18.89 cents per pound realized for the year's output of copper. With the exception of that year the dividends earned varied from $2 to $7; but in 1909, on 13.30-cent copper, the Osceola has paid a dividend of $10 per share, justifying public confidence in the superior ability of the Calumet & Hecla staff to operate efficiently a Michigan copper property. The average copper content of the ore stamped was only 16.9 pounds per ton, and the cost of production was forced down to 9.03 cents per pound.

CONSTRUCTION IN BOND for export is the basis on which the Fore River Shipbuilding Company, of Quincy, Massachusetts, has been able to underbid its over-sea rivals, and obtain the contract for two battleships for the Argentine Republic. Whenever one looks into the binnacle of the shipping industry, though the arrow points due north, the compass is found to be compensated against local attractions. The business, in none of its branches, ever seems to be conducted in the frank and open manner which admits of free competition. Even the building of ships in bond is not alone sufficient to yield an advantage so great as to enable the American to bid on each 'dreadnaught' $900,000 less than the lowest English offer. By this method the cheap foreign market for Pittsburg steel is transplanted under hot-house conditions to the fringe of our own protected country. While an American firm gets the contract, and more American laborers are employed, a large quantity of the structural material will be the product of foreign cheap labor, which should burn the fingers of the union workmen on Massachusetts Bay. The matter is full of perplexities for every class of theorist.

THE SENATE COMMITTEE on Mines and Mining has unanimously reported the bill for creating a Bureau of Mines at Washington. We are glad to note that the House bill is amended by providing for a Director at $6000 per year in place of a Commissioner at $5000. It is also provided that the Director shall be a man equipped by training and experience for the office, and in every possible way it is assured that the Bureau will be a scientific organization with a scientific man at its head. Any pretense of authority to inspect mines or supervise metallurgical plants is expressly disclaimed. All this is excellent, though the last merely puts into the act a recognition of facts which Congress itself could not have changed if it would. However, there has been such persistent misunderstanding of the purpose and functions of the proposed bureau that it is, perhaps, just as well to be even over specific. Omitting, however, the words, in defining the functions of the Bureau "to foster, promote, and develop the mining industries of the United States," is, we think, conservatism run wild. The phrase is common in the organic acts of various similar government bureaus, and we are quite unable to see where it is wrong "to foster, promote, and develop the mining industries of the United States" while right to do all these things in the case of agriculture and manufacturing.

Natomas Consolidated.

The Hirsch Syndicate, Limited, of London, has exercised its option to underwrite $5,000,000 of the bonds of the Natomas Consolidated of California. This will produce a favorable impression. The Natomas Consolidated represents the combined interests of the Feather River Development Company of Oroville, and the Natomas Development Company and the Folsom Development Company of Folsom, which were consolidated on January 1, 1909. The holdings of this concern consist in the main of 7000 acres of tested gold gravel deposits, 60,000 acres of valley land along the Sacramento and American rivers, ten operating gold dredges, eight of which are working at Folsom, and two at Oroville, and two rock-crushing plants at Folsom of 2000 and 1500 tons capacity respectively. Among the dredges is one having buckets of 13½ cubic feet capacity, which has become justly celebrated. This dredge handled an average of 8397 cubic yards of gravel per diem, or 251,910 cubic yards per month, during 1909. The delays in operation on this great dredge are reputed to have been less than 16 per cent throughout the year. Various estimates of cost have been unofficially stated, ranging from 2½ to 4 cents per cubic yard. Unfortunately the company has adopted a policy of secrecy that has aroused scepticism as to its achievements. Frank publication of data would undoubtedly remove the cause of considerable hostile criticism. The fact that the Hirsch Syndicate has assumed the responsibility of underwriting a $5,000,000 bond issue on the strength of a favorable report by so distinguished a mining engineer as Mr. Charles M. Rolker, would indicate that the company has no skeleton of operating troubles locked in its private office. The bonds are for a term of 20 years, bearing 6 per cent interest, and both principal and interest are payable in San Francisco, New York, or London. The denomination of the bonds is $500 and $1000. The capital stock of the corporation is $25,000,000 in $100 shares, approximately $11,500,000 having been issued. The stock is not listed on the Exchanges, but curb quotations range from $20 to $25. When the consolidation was effected, bonds

were authorized to a total amount of $25,000,000, divided into two classes, $15,000,000 of Class A, constituting a first mortgage on certain properties, and a second mortgage on others. The remaining $10,000,000, Class B, were the reverse of the former, namely, a first mortgage on the property pledged as second mortgage under the Class A bonds, and vice versa. Of these bonds $1,000,000 worth were sold for cash; the total amount issued, partly in payment for properties and for other purposes, being $5,261,000 Class A, and $2,500,000 Class B.

The money realized by this bond issue will be available within thirty days, and it is said that five additional dredges will be built at once. The valley lands will also be developed, and the prospects are that the colonization enterprise will surpass the gold mining operations as a producer of revenue. These low-lying lands, now subject to annual overflow, are of extraordinary richness. Building of levees has resulted in reclaiming large areas in the lower Sacramento and San Joaquin valleys, and such lands are in great demand. The Natomas Consolidated will become a factor of increasing importance in the development of the resources of California.

Individualism or Collectivism.

Speaking of the common miscarriages of justice in America, Judge Curtis H. Lindley gave expression to some advanced thought in a recent address on 'Reform in Our Legal Procedure' before the Commonwealth Club of San José, California. He remarked that "exaggerated respect for the individual as the 'isolated centre of the universe', which has come down to us with its seventeenth century coloring, is the cause of most of our troubles. Ever since the beginnings of legal instruction in America the neophyte has been saturated with the Blackstonian postulate which subordinated and circumscribed the social group to the strict narrow standard of the individual. The ancient dogma of the common law that 'the public good is in nothing more essentially interested than in the protection of every individual's private rights', placed the individual above society."

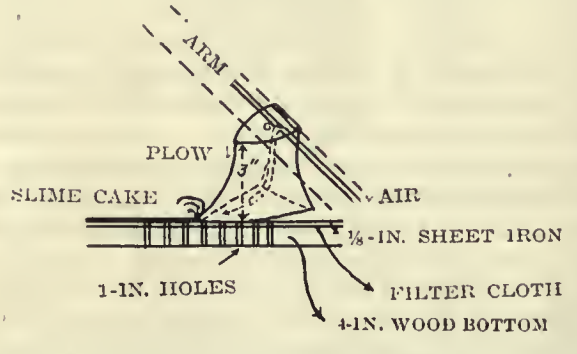
This is capable of a wider application than that involved in the 'adjective law', as the machinery of justice is called. It is important as showing the tendency of legal opinion. The conceptions of the leading lawyers exert their influence upon the judges through pleadings at the bar, and get written as case-law, thus establishing the course of social evolution. The crystallization of custom into law, whether of the legislature or of the bench, largely determines a people's attitude toward the great problems of life, and the customary thought of the age finds no surer index than the utterances of so distinguished a barrister as Judge Lindley.

We have pointed out in previous editorials that the decisions of the Western courts during recent years have been notable for the emphasis laid upon one and the other extreme of this question of individualistic right. The matter is somewhat complicated by the mingling of diverse legal principles where the common law and the civil code have come into conflict in the Southwest. The view of the people in the territory absorbed from Mexico has been greatly influenced by the laws and customs originally prevailing, and which in many respects were peculiarly adapted to the physical conditions there existing. It was only a few days ago that Chief Justice Kent, of Arizona, in deciding the famous Salt River valley case (Hurley *v.* Abbott), rejected the common law doctrine of riparian rights so far as they interfere with the use of water for irrigation. Furthermore, Judge Kent recognized individual claims to consideration, to the extent of fixing the status of every piece of land in the valley, involving more than four thousand defendants. The decision is in line with the deference shown to the individual in the case of Arizona Copper Company, Limited, *v.* Gillespie. This is the most recent deliverance from the bench in line with the precedent established in California in the débris case (Woodruff *v.* North Bloomfield Gravel Mining Company), and in Utah (McCleery *v.* Highland Boy Mining Company), where the judge affirmed that "public policy is more concerned in the protection of individual rights than in the profits to inure to individuals by the invasion of those rights." Some famous cases on the other side have been the Mountain Copper in California, the Bunker Hill & Sullivan in Idaho, and especially the Anaconda smoke-case in Montana. The decisions in the Anaconda and the Arizona Copper cases represent the most recent expressions of judicial opinion on opposite sides of this question. The Arizona case has been appealed to the Supreme Court of the United States, and the Anaconda dispute is to be reviewed in the ninth circuit of the Federal Court. The outcome of these important cases will go far to determine the future trend of social evolution in the West. Just now it is toward relaxation of the old common law zeal in protecting the man as an independent agent, while the rights of society are elevated. It is a matter of units; the molecular rather than the atomic social unit is attracting attention in the effort to better regulate the body politic. We cannot help looking upon the pioneer miner and homesteader, hewing success out of hard conditions by individual brawn and heroism, as a type the loss of which involves a loss of inspiration. The protection of the individual means the protection of this kind of initiative and wholesome endeavor. It was a class characteristic of the pioneer days, which has almost been swept into the limbo of the past. The social structure of today is built on the foundation laid by men of that class. It may be time to put away the old style along with the top-boots and the patriarchal beards of the Argonauts. Judge Lindley has shown, not only his personal viewpoint, but that of a growing number of thinkers in the West. The application of his doctrine to criminal law need not concern us here; it would lead to swifter and perhaps more even justice. The question that lies near to us is what the effect will be in the struggle between the small operator and the corporations that are daily growing more powerful through gigantic combinations. The way of evolution is the way of necessity, and whatever one or another may think or say, that which means in the end the greatest good to the greatest number will triumph.

Cyanidation of Concentrate.

Written for the MINING AND SCIENTIFIC PRESS
By A. E. DRUCKER.

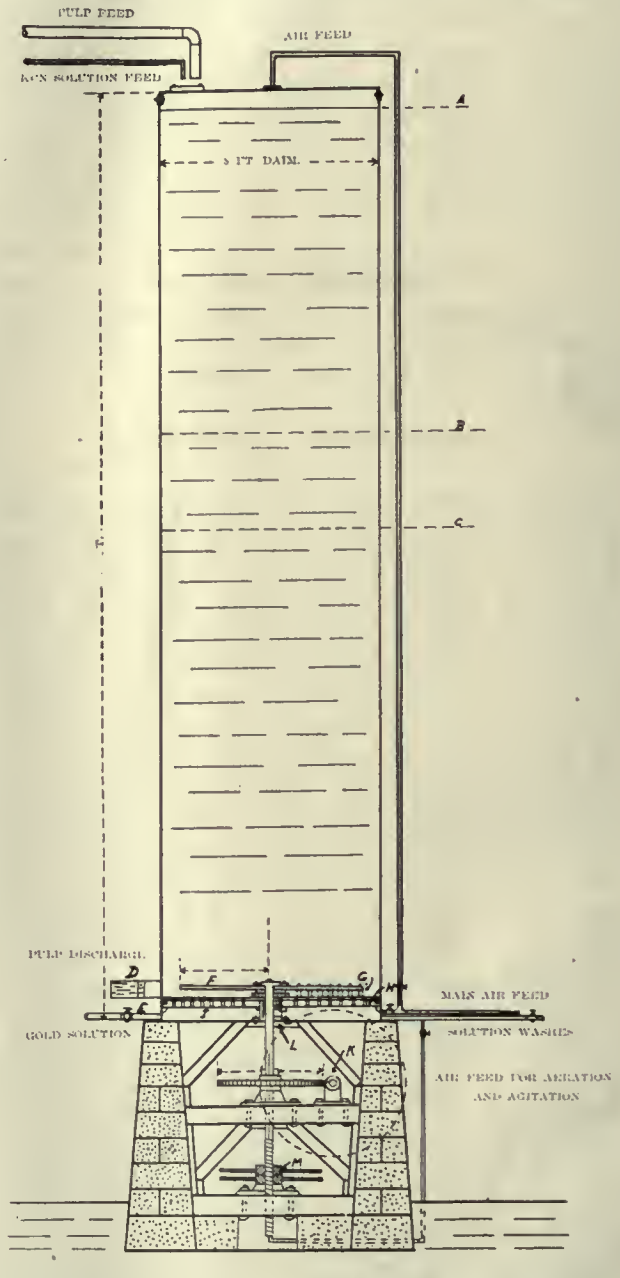
After about three years of experimental work in Korea with the Oriental Con. M. Co., in connection with the treatment of sulphide slime, and also after an 18 months tour and study of cyaniding methods in India, New Zealand, Australia, South Africa, and the United States of Ameriea, I have come to the conclusion that the combined air-agitator and continuous leaching vat as shown in the drawings accompanying this article is the most economical and effieient system of any in use at the present time for the treatment of a high-grade slime containing gold and silver. This agitator is the result of selecting the good points of other styles I have seen in various places. What I claim as being original is the arrangement and device for keeping the bottom filter free from slime-cake, thereby allowing the gold-bearing solution to leach through the slime and to pass the filter to the zinc-boxes, while at the same time the pulp is being aerated and air-agitated. This agitator is par-



ticularly adapted to the cyanide treatment of gold and silver-bearing sulphide slime, and in fact to any other high-grade slime where it is desirable to get the highest possible extraction in the shortest time.

These agitators may be made in three sizes: 15 by 6 ft. diam., 10 tons capacity; 25 by 7 ft. diam.; 20 tons capacity; and 35 by 8 ft. diam., 40 tons capacity, all dry weight. These are the figures given for a clean sulphide slime. The consistenee of the sulphide slime under treatment is about 1 to 1 by weight. All details of construction of this combined agitator and leaching vat will be found in the drawing. There are four arms F at right angles to eaeh other, revolving at about 6 rev. per min., and to these are attached 26 east-iron double plow-shoes G equally spaced. The shoes on opposite arms are arranged to work in between, so as to keep the whole filter-bottom free from slime-cake.

The cloth filter is well braced about 6 in. from the bottom, and ean neither bulge one way nor the other under pressure or vacuum. This filter-bottom consists of 3-in. pine boards H, bored with 1-in. holes, and placed as elosely together as possible. In addition to these holes the top of the 3-in. boards are grooved so as to get the full benefit of the filtering area when the eloth is placed above and ealked to the sides of the vat by means of a rope. As a proteetion to the filter-eloth a ⅛-in. sheet-iron eover, bored also with 1-in. holes to eorrespond to the 1-in. holes below in the wood bottom, is placed on top of the cloth and secured. The filter-cloth is between, and the inch holes above should coincide with those below, as is shown in the drawing. The plows G attached to the arms F can be easily raised or lowered 2 or 3 ft. by means of the lower threaded end of the vertical driving-shaft. This is important if it should be desired to stop the agitator while the pulp remains in the vat. These plows are driven by means of the worm-gear K beneath the vat. On stopping, the arms are raised, say 2½ ft., and the slime allowed to settle. On starting again, the plows are set in motion and gradually lowered through the settled slime until



the points just begin to touch the filter. There it is made secure by means of a clamp wheel M on the threaded end of the vertical driving-shaft. The plows revolving close to the filter prevent any slime-cake from forming, thereby allowing continuous leaching from above of the gold solutions into the compartment I beneath the filter, and thence to clarifying presses or sand-tanks, through which the elear solution passes to zinc-boxes.

There is no trouble in lowering the arms when plow-shaped shoes are attached. I have never found any other form of shoe that would suecessfully work down on this heavy thiek sulphide slime after it was

once allowed to settle, especially the last layer of slightly coarser material next to the filter, which packs like cement.

An agitator of this type is particularly adapted to the treatment of heavy sulphide slime. There is always a small amount of fine concentrate that is bound to escape into an agitator from the classifiers, even though all is ground to pass a 200-mesh screen. With a sulphide, the coarser portion passing a 200-mesh screen will give serious trouble to any other form of agitator upon allowing the charge to settle, on account of being unable to work down on a cemented sulphide.

Compressed air for aerating, agitating, and softening of cake is introduced through the hollow vertical driving shaft, and from the top is conveyed by means of small pipes to the points of each plow as shown. At the end of each air-jet within the plow a rubber nipple is attached, so that when air is being forced through the nipple expands and allows the air to do its work. When the air is turned off the nipple contracts, preventing any slime from entering the pipes and clogging them. The air-connection at the bottom of the hollow shaft is made by means of a swivel and rubber hose, so as to allow a vertical movement upward or downward of the arms to which the plows are attached.

The object of forcing air beneath the cutting-points of the plows is to somewhat soften the cake, thereby helping the plows in their work. At the same time this air is being well distributed at the bottom of the vat, and bubbles up through the charge, keeping the pulp well agitated and preventing settlement of the slime. Everything seems to be actually boiling. Aeration and agitation are perfect at every point of the vat. Each agitator has a friction-clutch beneath the vat for starting or stopping the plows. With four of these vats placed in a row one main horizontal line-shaft *K* drives all, a friction-clutch being needed for each vat.

The vertical driving shaft to which the arms are attached passes up through a stuffing-box *i* in the bottom of the vat, so as to prevent leakage of solution pulp at the entrance of the shaft. This packing box is placed so that it can be readily tightened from beneath the vat when required. After removing the first strong cyanide solution down to about 30% moisture by means of pressure-filtering, all subsequent barren cyanide washes, if necessary, are to be forced up through the vertical driving shaft, and out through the pipes on the arms to the points of each plow. By this means the wash is added at the bottom of the vat and works itself upward through the thick pulp, giving a perfect mixing and wash. After sufficient wash-solution has been added it is turned off, but the arms are caused to rotate, while pressure-filtering is resorted to for driving the solution through the filter to the zinc-boxes. When this operation is complete there remains about 30% moisture within the thick pulp. This slime is forced into a filter-press where it is given a weak wash, and the 3-in. cakes finally discharged as residue with about 10% moisture.

With a 40-ton vat (8 by 35 ft.) treating clean sulphide slime, and requiring a 4-day treatment, the following power is necessary:

40-TON CHARGE.

	Horse-power.
For driving short arms (intermittent power)	1
Air agitation (15 cu. ft. air per min. at 26-lb pressure; intermittent power)	1½
Total intermittent power	2½
Continuous power	2
Continuous power per ton treated	0.05

The operations can be divided as follows after all-sliming the sulphide within a tube-mill in cyanide solution, taking for example a 4-day treatment:

1. Collecting a full charge in agitator (undergoing an air-agitation and leaching while filling).....24 hours
2. Air-agitation and continuous leaching (cyanide solution carrying gold and silver, continuously flowing to the zinc-boxes; pulp finally pressure-filtered down to 30% moisture before washing).36 hours
3. Intermediate barren cyanide wash (mixing and finally pressure-filtering down to 30% moisture before sending to filter-press).....12 hours
4. Filter-pressing, weak wash, discharging.....24 hours

Total ..... 4 days

ANALYSIS OF SULPHIDE SLIME TREATED IN KOREA.

No. 1 Sulphide.

	Per cent.
Iron pyrite (FeS_2)	56
Galena (PbS)	36
Sphalerite (ZnS)	6
Arsenopyrite (FeAsS)	2
	100

No. 2 Sulphide.

Arsenopyrite	72
Marcasite	27
Galena, Sphalerite	1
Copper pyrites	traces
	100

The No. 1 sulphide carries from $40 to $50 in gold. Only a fraction of an ounce of silver is present in this sulphide. An actual extraction in bullion of 92 to 94% was obtained by my combined agitator and leaching-vat at the experimental plant in Korea during 1908. The old method of leaching No. 1 sulphide (without all-sliming in tube-mill) for 18 days in shallow vats, with strong cyanide solutions, gave an extraction of 84%. No. 2 sulphide carries from $20 to $30 in gold. A 16-day leach in shallow vats (without all-sliming) gives an actual gold extraction of about 70 to 75%. Upon all-sliming this sulphide in a tube-mill, and finally treating in my combined agitator and leaching-vat, the extraction was increased to 92% with only a 4-day treatment. Costs depend upon conditions, and these vary greatly in different parts of the world. In Korea our expensive item is power, while labor is cheap and efficient. A comparison between old and new methods of treating sulphides in Korea per ton of clean sulphide treated (1200 tons per month), shows: (1) Old method, 18-day leaching in shallow vats, estimated at $2.17 to $2.37; new method, all-sliming and tall air-agitators, estimated at $2.75 to $3 per ton of ore milled or concentrated (20,000 tons per month). (2) Old method, 13 to 14c. (taken from company report); new method, 16 to 17c. (estimated).

In a great many places (Australia, America,

Mexico, and New Zealand), the ore is concentrated before cyaniding, and the sulphide concentrate shipped to the nearest smelter for reduction, the owners being content with high smelter and transportation charges. Besides, the smelters do not completely extract the precious metal. If one realize 95% of the true assay value he is lucky, after taking into consideration the percentage of moisture and improper sampling. Why ship concentrate to smelters that can be successfully treated by the cyanide process? The majority of gold and silver-bearing sulphides can be treated on the spot at a far better profit than by shipping to the smelters.

Most sulphides (concentrate) offer little trouble to a successful cyanide treatment provided the following points are observed: (1) To be treated fresh and re-ground in a tube-mill with strong cyanide solution (0.15 to 0.20% KCN) so that the resulting product going to the agitator will all pass a 200-mesh screen. (2) To be air-agitated and aerated in the combined agitator and leaching vat shown in the drawing. Treatment from 20 to 36 hours. (3) It is a very important point to continuously leach at the same time the pulp is being air-agitated, so that at the end of the 20 to 36-hour treatment practically the bulk of the gold and silver has been deposited in the zinc-boxes. This method gives excellent results. It not only cuts down on the time of treatment to a large extent, but also avoids the numerous washes formerly required with the old methods of agitation in one solution. (4) Keep an eye on the protective alkalinity of the cyanide solutions. Do not attempt to use cyanide solutions testing only 0.05 to 0.15% KCN and expect to get good results in a 20 to 36-hour agitation. About 0.25% in free KCN I find suitable for most sulphides. Use KCN in preference to NaCN, when air-agitation is employed. KCN gives the best results at a less consumption of cyanide. (5) Do not allow the strong cyanide solution to become so foul as to become inactive. This is one of the serious troubles in treating sulphides. A newly made solution, free from reducing agents, will give the best extraction, and have the greatest dissolving power, but as it becomes older and takes up various foreign substances, which act as reducing agents, robbing the solution of its oxygen, the extraction gradually falls. The cheapest and most effective way of maintaining the extraction and overcoming this reducing action is by a thorough aeration while agitating the pulp with cyanide solution. In treating concentrate (sulphide) it is not a bad plan to make a new strong solution every six months.

The relation between volatile matter and efficiency in coals used in house-heating boilers is of particular interest to people using coal from the central part of the country, as in Indiana, Illinois, and Iowa, as these coals contain much volatile matter. The volatile content of the coals tested recently by the United States Geological Survey ranged from 18 to 44%, and as the volatile matter increases the efficiency decreases, for much of the volatile passes out of the stack unconsumed. The efficiency is 60% with coal containing the least volatile matter, but is reduced to 47% for coal having the greatest amount.

STANDARDIZATION OF ASSAY TERMS.

The Committee for standardization of bullion and assay values, of which G. T. Holloway is chairman, has reported to the Institution of Mining and Metallurgy, and the matter is now being discussed. The Committee was formed for the purpose of recommending rules which should, as far as possible, be followed by assayers, metallurgists, and mining men, in reporting the results of assays and tests of which assays form an essential part, so that ambiguity should be avoided and the possibility of misinterpretation or misuse of reports minimized. Reports of assay results, extraction tests, metallurgical and ore dressing trials, are sometimes so worded as to permit a wrong interpretation, and the Committee urges the necessity for definite statements as to the nature and condition of the sample as assayed, and, where advisable, an indication of the method of assay. Thus, in the case of such metals as copper, tin, lead, antimony, etc., where both 'wet' and 'dry' methods of assay are in use, results should be reported as obtained by 'fire' assay or by 'wet' assay, with further details as to method, if judged advisable. Similarly, a statement should be made as to whether the sample was assayed in the condition in which it was received, was 'air-dried', or dried at—°C. In reporting that an assay for such a constituent as tin, arsenic, tungstic acid, etc., corresponds to so much 'black tin', 'white arsenic', 'wolfram' or other recognized salable product, the report should give the assay result for such constituent, together with a definite statement as to the figures used in calculating such salable product. Thus, an assay showing 1% of metallic tin might be reported as 1% of metallic tin, equivalent, if all could be extracted as such, to 1.5% of 'black-tin' containing 66.6% of metallic tin.

The Committee submits the following recommendations for adoption by the Institution: (1) Assay reports shall state the exact condition of the sample as to dryness when assayed. (2) Assay values of gold and silver ores and products shall be represented in pennyweights and decimals or in ounces and decimals, and not in ounces, pennyweights, and grains. They shall be expressed in terms of fine gold and fine silver respectively, not as 'bullion'. (3) Assay values of alluvials shall be reported in grains and decimals of a grain of 'fine' gold, or in pence (at 2d. per grain of 'fine' gold), or cents per cubic yard. It is recommended that, in the absence of specific information, one cubic yard of ordinary alluvial, excluding boulders, be taken as equivalent to 3000 lb. (1½ short tons). (4) In reporting assay values of cyanide and other solutions, the results shall be given in parts by weight in a stated volume of the solution. (In the case of cyanide solutions, the use of the 'fluid ton of 32 cubic feet' is recommended. It closely approximates to 2000 lb. and is in common use.) (5) When it is necessary to state or estimate the money value of an ore, etc. (other than of gold), it shall be accompanied by the assay value, and the basis on which the former has been calculated from the latter shall be stated. (6) Laboratory sieving tests shall be made with the I. M. M. Standard sieves, or else the widths of the apertures shall be stated.

Reopening the Mexican Mine, Comstock Lode.

Written for the Mining and Scientific Press
By Whitman Symmes.

Although the Mexican mine contains the deepest workings on the Comstock Lode, it has never produced enough ore to be worth mentioning. The only ore milled from the present Mexican area consisted of 308 tons, assaying $13 per ton. This was taken from a stringer on the 2700-ft. level in 1883. In 1884 the Mexican 3100-ft. winze was sunk to the 3300-ft. level, and three diamond-drill holes were driven out. The results being disappointing, all work in the lower levels at the north end was discontinued, and from that time until recently, no work has been done in the mine below the Sutro tunnel level, at a depth of 1600 ft. In 1906 a drift 215 ft. long was driven north from the Mexican-Ophir line on the 2000-ft. level, but this yielded no results, and for a couple of years there was not a miner engaged in the Mexican workings.

In July 1908 a drift was started north on the

Fig. 1. Union Hoist, Virginia City.

Fig. 2. Consolidated Virginia Mine.

2200-ft. level, on which the Ophir was working a body of good ore only 70 ft. from the Mexican line. When in 215 ft., this drift picked up a small vein of quartz (now known as the 'west vein'), from 2 to 5 ft. wide, and assaying from $5 to $30 per ton. The ore-shoot thus exposed, however, was only a few sets long. In the spring of 1909 I was placed in charge, with the usual instructions to find a body of pay-ore in the shortest possible time.

The conditions for mining, however, were unusually bad. The company then had a one-third interest in the Union shaft, which has a modern plant, but the territory it was desirable to explore was not connected therewith. The only access was by way of the C. & C. shaft, and the Con.-Virginia and Ophir workings. Waste had to be trammed to the shaft, and timbers brought in through nearly 2000 ft. of drifts, 500 ft. of which was through the 2350-ft. Con.-Virginia 'snow-sheds', where the thermometer showed the exhilarating (?) temperature of 122 to 132°F. The mine was lacking in equipment. The rock-temperature in the Mexican drift was 107°F., and the air for ventilation, which was furnished by the Ophir management from their own insufficient supply, was 103°F., and the current was scarcely strong enough to make a candle flicker. The compressed air supply which came all the way from the shaft through a 2-in. pipe, and did yeoman's service on the way, had an unaccommodating habit of periodically dropping to 45 lb. Under the circumstances I could not muster much enthusiasm for 'following the ore'. A vision of balmy adits, fresh air, and other precursors of efficiency, presented itself as an overpowering attraction.

For many months, therefore, the Mexican did only 'dead work'. A south drift from the Union shaft workings on the 2000-ft. level was driven to a connection with the Ophir workings. A natural draft of air thus circulated along that level and up the Ophir incline, which is the up-cast for the north end mines. A blower was installed on the 2000-ft. level, and a relay blower on the 2200-ft.; and these delivered air to the Mexican 2200-ft. drift through a maximum of 1200 ft. of 15-in. pipe. By this means a fair supply of air was obtained. A 2-compartment raise was then driven to the 2000-ft. level, at about the centre of the Mexican territory, and was connected with the drift from the Union shaft. The raise (or winze, as it is now called), thus became a down-cast, and the Mexican and Ophir now have an abundance of cool dry air, circulating naturally through their 2200-ft. drifts. Although the immediate objective work was upon the 2300, 2400, and 2500-ft. levels, the 2000-ft. level was chosen for access to the ore-zone, instead of some deeper level, for the reason that the former has been for a considerable time drained of all hot water and is now cool. Thus the 1850 ft. of tramming is made easier, and the air-supply reaches the ore-zone with a minimum addition of heat and moisture, which would not be the case were connection with the Union shaft made at a lower horizon, near the water level. The present temperature at the station of the Mexican 2000-ft. winze registers 87°F. The wet-bulb temperature is 73°, showing only 53% saturation. The amount of air passing through the drift in January, 1910, was 22,000 cu. ft. per minute.

On the 2000-ft. winze-station was placed a No. 6 Sturtevant multivane fan, direct-connected to a 20-hp. motor, with a speed of 1120 rev. per min. It is rated at 13,500 cu. ft. per minute against a 2-in. water-gauge, with a consumption of 22 brake horse-power, 11,060 cu. ft. against 4-in. pressure, taking 19.5 brake horse-power, and 8500 cu. ft. against a 5-in. water-gauge, with a consumption of 16 brake horse-power. A 20-in. trunk-line pipe runs down the winze, with 15-in. branches on the different levels.

The 2400-ft. station is thus kept down to 90°F. By a simple arrangement of gate-valves the fan is made to suck air after blasting and to deliver the smoke into a drift that connects with the Ophir up-east. On the same station was installed a double-drum electric hoist, driven by a 30-hp. A. C. motor, with a maximum hoisting speed of 450 ft. per minute. In putting through the raise, progress was limited by inability to handle more than a certain amount of waste. Therefore the Mexican winze is constructed with only two compartments. The single cage is balanced by a counterweight in the compartment used as a pipe and ladder-way. The maximum load when hoisting a car with 1800 lb. from the 2400-ft. station is 1700 lb., and when hoisting the counterweight and lowering the empty cage it is 1630. Waugh stoping drills were used in raising, with Waugh 'sinkers' for plugging. In driving and sinking Sergeant 2½ and 3-in. machines are used. The Waugh 'sinkers' are not regularly used for sinking, as they cannot keep the holes sufficiently clear in the stiff clay that is encountered.

The results of this preliminary work at once became apparent. Previously the 'pass' system had been necessary. In the hotter and more humid headings on the Comstock, the men work a 'pass' at the face and then go out to the cooling-station to cool off: but since obtaining the Mexican air-connection with the Union shaft the 'pass' system has been abolished, and all miners in the Mexican mine now put in a full shift at the face. The labor-cost of driving immediately dropped to 46% of what it had been under the previous management for the entire mine, and to less than 40% for the drifts connected with the Mexican winze. The labor-cost in the winze drifts for the past three months has averaged $5.50 per foot, the wages of all men underground being $4 per day. Most of the rock was a fairly hard diabase, but some was soft vein-matter and required timbering. The cost of driving is considerably increased by hoisting in the winze and shaft, tramming 1850 ft. on the 2000-ft. level, and by fixed expense, which features are now receiving attention. Apart from the general pumping expense, in which the mine shares, there is no reason why work may not soon be conducted as economically as in other places which have similar rock, and where equal wages are paid.

The principal orebodies at the north end of the Comstock Lode (excepting on the outcrop) have not been found in the main 'vein', but in branch fissures which extend from the Comstock vein-matter upward into the hanging wall. This formation is shown in Fig. 4, which gives a composite cross-section, east and west, through the Con.-Virginia and Ophir. The time honored method of prospecting on the Comstock has been to drive lateral drifts and cross-cuts at random through the main 'vein' and hanging wall, and then to follow any promising stringers that were thus found. At the north end there is a belt in the hanging wall more than 800 ft. wide, sufficiently decomposed in places to have been classed by the old-time miners as vein-matter, and as this belt contains a million stringers it will be seen that the old method was a task of some magnitude. Drifts were formerly driven on all sides of

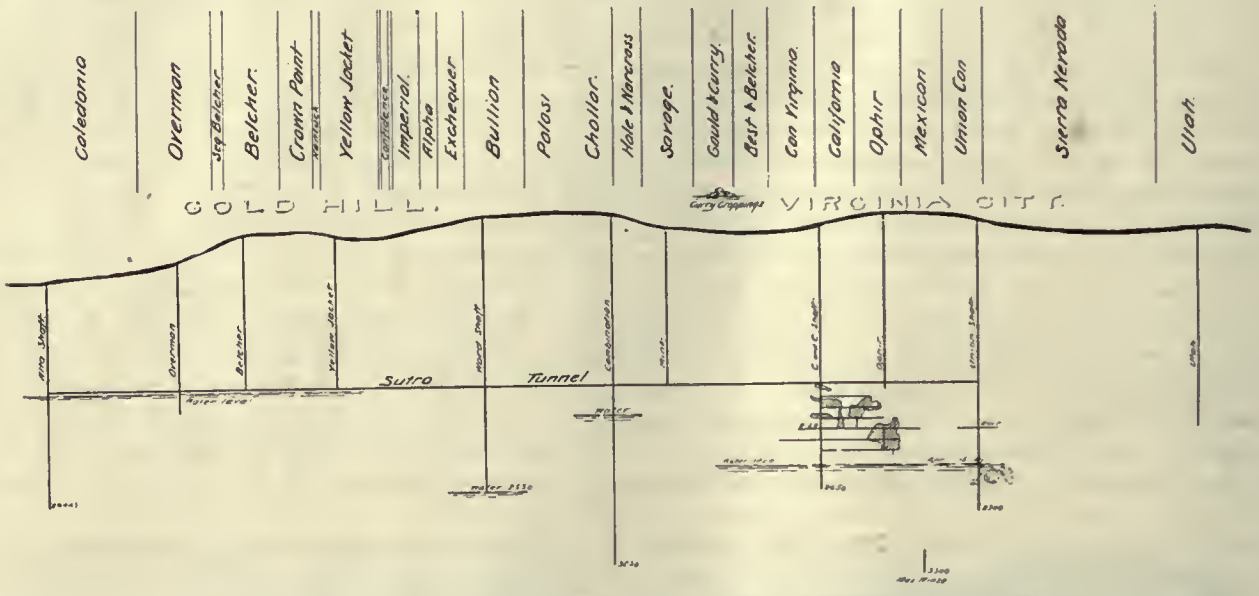


Fig. 3. The Comstock Lode Showing Water Level in 1909 and Ore Extracted Since 1890.

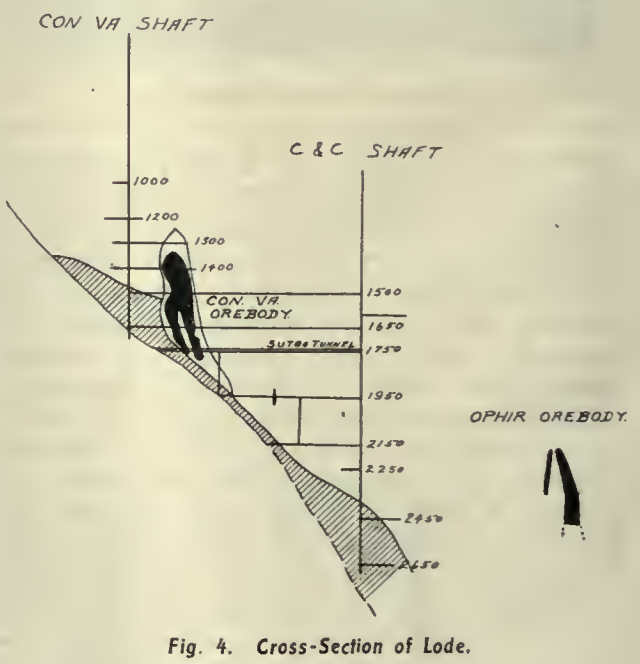

Fig. 4. Cross-Section of Lode.

the orebody lately worked in the Ophir without suspicion of its presence 250 ft. above.

Becker states:[1] "Openings of the type of that which contained the Con.-Virginia and California

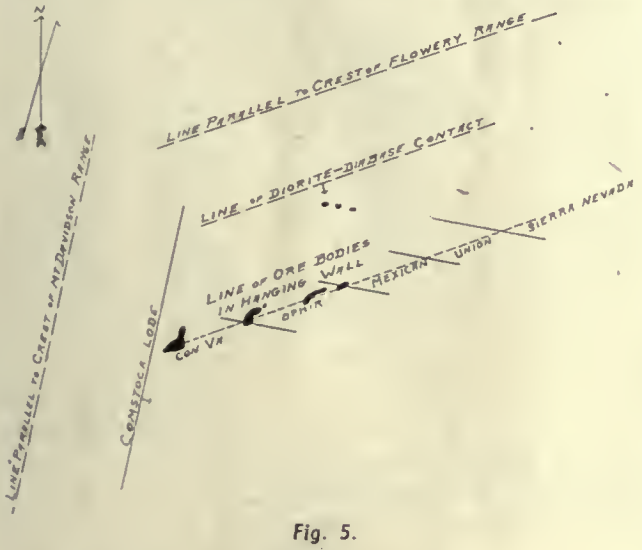

Fig. 5.

bonanzas may occur at any point on the vein, and wholly without warning from above, as was the case with that body." He believed that the orebodies occurred near points of non-conformity of the hanging and foot-walls of the lode. Church,[2] who examined the Con.-Virginia bonanza some years previous to Becker, was of the opinion that the Con.-Virginia ore was in the main Comstock vein-matter. In 1905 John A. Reid[3] made a study of certain portions of the Comstock district, giving most of his attention to the cross-faults which he found on the surface. Unfortunately he was not allowed more

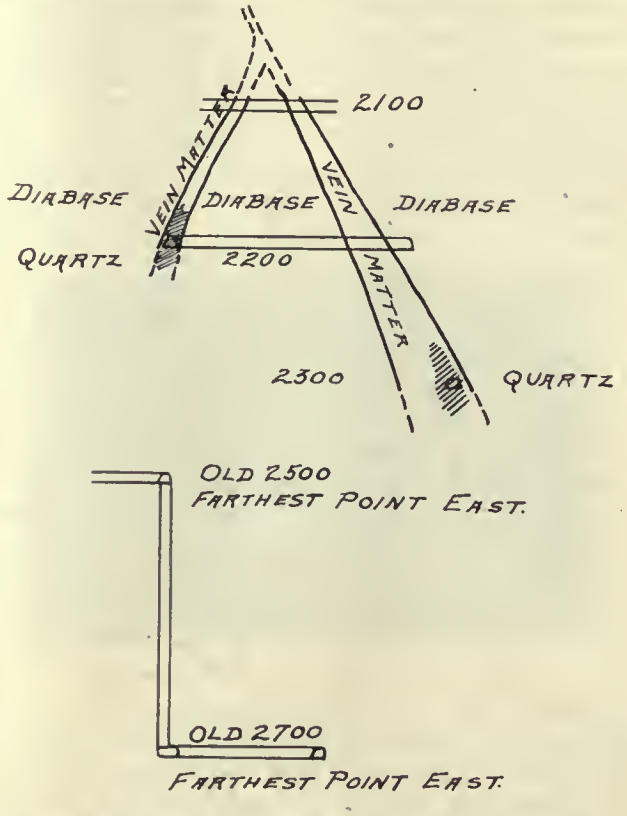

Fig. 6. East-West Cross-Section, near Mexican-Ophir Line

than a momentary inspection of the deeper mine-workings. He proposed that the ore-bearing gashes

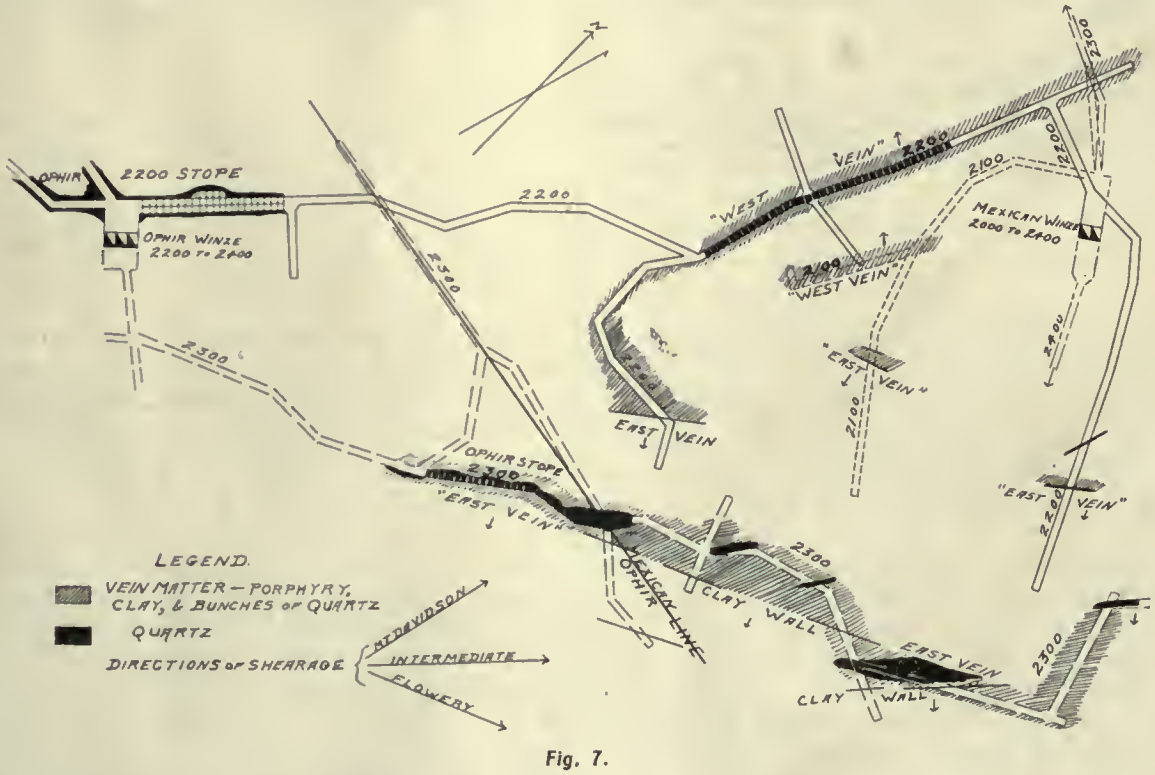

Fig. 7.

that extended from the main vein-matter into the hanging wall should be known as 'rifts'. He stated that other rifts might be found by driving exploratory drifts farther east and at greater depth, but was able to offer no more satisfactory advice.

In 1909 I began an investigation of the structural geology of the north end with a view to obtaining data for guidance in a search for ore in the Mexican

[1] 'Geology of the Comstock Lode and the Washoe District'. By Geo. F. Becker. Washington, 1882; p. 287.

[3] 'The Structure and Genesis of the Comstock Lode'. By John A. Reid. Univ. of Cal. Publications, Vol. 4, No. 10; pp. 177-199. The University Press, Berkeley. 1905.

ground. I found that the hanging wall was sheared in two principal directions and that the orebodies had been deposited in rifts in the hanging wall along the zone of intersection of these shear-planes. One series contains shearing parallel to the contact of the diabase of the hanging wall, with the diorite of the Mount Davidson range on the west, that is, parallel with the main Comstock Lode; and the other series contains shearing parallel to the contact of the hanging wall diabase with the diorite of the Flowery range on the north, along which contact lies the east fork of the Comstock vein-matter (Fig. 5). The ore has been deposited in rifts made by these two shearing movements. A series of intermediate shearing also exists, bisecting the angles made by the other two, and bringing 'feeders' into them. I projected the plane of the intersection of the Davidson and Flowery shear-zones into the Mexican ground and found it to lead to the east of all the old workings. Accordingly last August I persuaded the Ophir management to join with the Mexican in driving an east cross-cut from the Ophir northeast drift on the 2300-ft. level, the cross-cut following the boundary line between the two properties. The Ophir joined reluctantly, because it was the opinion of its superintendent and foreman, who had spent their lives on the Lode, and are experts in the 'stringer method' of prospecting, that no ore could be found in that

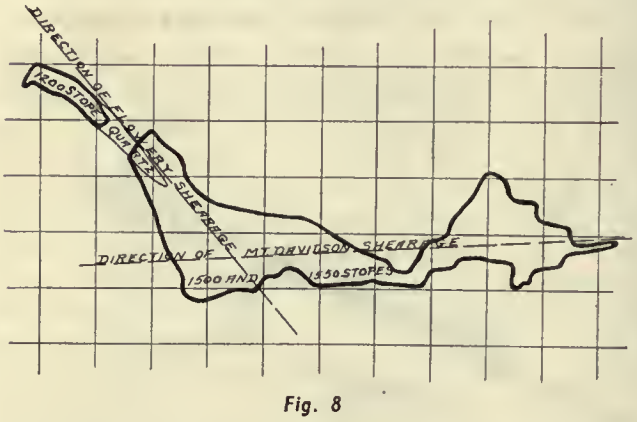

Fig. 8

direction. The joint east cross-cut, however, exposed the junction of the shear-zones, and with it a 10-ft. vein of quartz. The Ophir drove southwest along this 'east vein' and has stoped ore for a length of 60 ft. The 'sets' averaged from $18 to $58 in value, but the ore extended above the 2300-ft. level for only four sets. The Mexican started northeast through ore that averaged as high as $65, but when the drift had been advanced only 20 ft. the quartz suddenly gave way to clay and porphyry. The vein-matter has now been explored for a distance of 250 ft. northeast from the Mexican line. It is composed mostly of clay and decomposed diabase, with bunches and veinlets of crushed quartz of low assay value. A few small bunches, however, gave good assays, some as high as $120. It may be noted, in passing, that the 1100-ft. level of the Con.-Virginia, which tapped the upper tip of the 'big bonanza', went through a similar soft leached zone, and had to be closely timbered.

The ore extracted by the Ophir and Mexican from the 'east vein' is identical in mineralogical composition with the other orebodies of the north end. Exploration has also shown the structural formation to be the same. The 'west vein' in the Mexican lies in the Mount Davidson shear-zone, a little north of its junction with the Flowery range zone. It is a spur from the 'east vein' and dips to the west, while the latter dips to the east. It is shown in cross-section in Fig. 6. On the 2100-ft. level it contains only clay and bunches of crushed quartz of no value. On the 2200-ft. level, however, it shows a firm clean-cut lens of quartz for about 70 ft., with clay and crushed quartz of no value between the vein-walls at either extremity of the lense. The quartz averages from $10 to $30 in assay value. The exploration of this vein, on the 2300-ft. level, is now about to begin.

The east vein does not lie along a single shear-

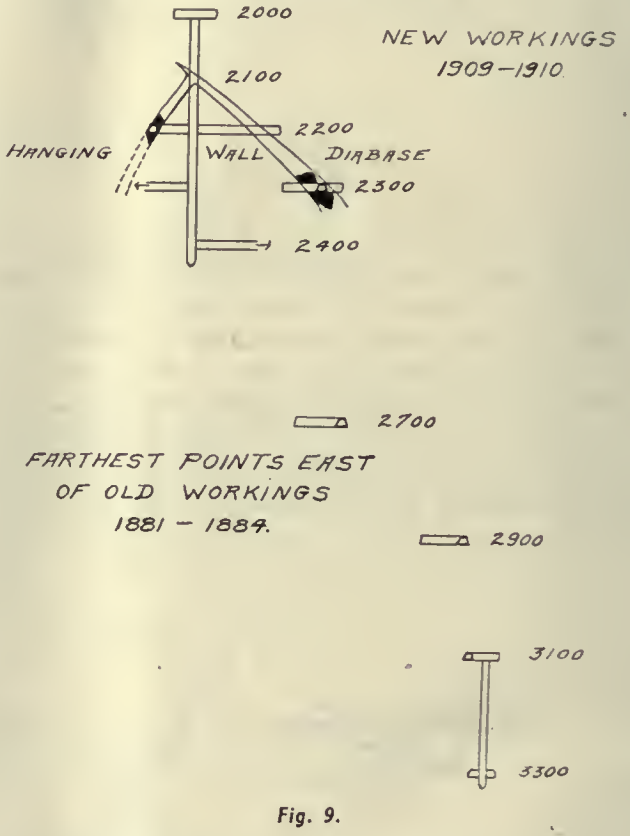

Fig. 9.

zone, like the west vein (Fig. 7). At the south, in the Ophir, the quartz follows the Flowery shearing, which is the only one that is there well defined; but in the Mexican ground there is a combination of shear-planes, and the quartz is found mainly in the intermediate sheared area, at and near the junctions with the Flowery shear-planes. In the Con.-Virginia, Ophir, and Mexican, the formation appears to be identical. Valuable deposits of quartz appear to originate along these three shear-zones only. In the larger orebodies, where the hanging wall has been considerably shattered, and the three shear-zones above mentioned are intermeshed with numerous minor shear-planes, jointings, and east and west faults, the wall-rock between the principal shear-zones has to a large extent been replaced by quartz. A vertical section through the Con.-Virginia bonanza would show a zig-zag outline, due to the shearing having different hades. In Fig. 8 the direction of the two principal shear-zones, as found in the Mexican, are superimposed upon a plan of the Con.-Virginia bonanza. It may be noted that in the latter, as in the present Ophir-Mexican orebody, on the

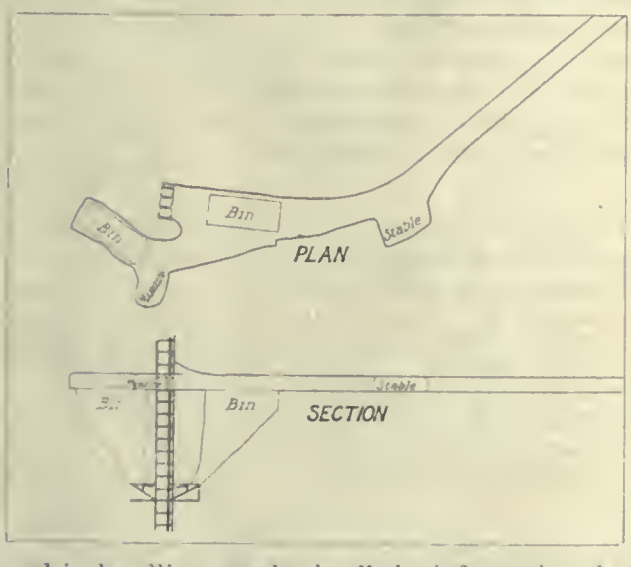
upper levels the ore appears at the south end, and in the Flowery shear-zone only.

The structural geology of the Comstock is complicated, and has never received an amount of study commensurate with its importance. The north end has already reaped some benefit from such work, and I believe that the middle and Gold Hill areas can also obtain similar benefits. The pumps at the C. & C. shaft are now lowering the water-level at the north end below the 2300-ft. level of the Mexican and Ophir, where it has stood for several years. Both of these mines have sunk their winzes to the 2400-ft. level, and are now cross-cutting toward the east vein. Whether or not they find ore there will merely determine the size of the one particular ore-body that has lately been stoped on the 2300-ft. level. The important fact has already been demonstrated that good ore can and does exist to the east of all former workings in this part of the Lode (Fig. 6); and it would also appear that exploration on the Comstock, by following stringers, is an antiquated method that must now give way to quicker, surer, and more scientific work.

EXPLOSION AT MEXICAN MINE, ALASKA.

Written for the MINING AND SCIENTIFIC PRESS
By ROBERT A. KINZIE.

At 11:30 on the night of March 2, 1910, a powder magazine on the 1100-ft. level of the Mexican mine, of the Alaska Treadwell Gold Mining Co., Douglas Island, Alaska, exploded, killing 37 men and injuring 9. The accompanying sketch shows the position of the mine-magazine. A description of the method



used in handling powder is all the information that can be given in regard to the explosion. Powder is delivered to the mine-magazines, one of which is provided on each level, once every 24 hours. Sufficient powder is delivered to supply the night and day shifts. In the case of this magazine the amount is between 20 and 30 boxes. This magazine furnished powder for the 1100-ft. level only.

The magazine in question consisted of a chamber, cut out of the rock for this purpose, and boarded up in the front. A partition divided the magazine into two rooms, and each room had a door. The door has an open grating through which the interior of the magazine can readily be seen from the outside. These doors are always kept locked, except at 'powder time', when a stope-boss is in the magazine to pass out powder to the miners, who call there for it.

The magazine is lighted by an incandescent 16 candle-power light, which is situated a short distance inside the door, no wiring crossing the stored powder. There is no heat brought into the magazine, as all powder is always thawed before being delivered to the separate mine magazines. The situation of the magazine near and beyond the shaft excludes the possibility of any men being cut off from escape in case

Magazine Marked by X X at 1100-Ft. Level.

of accident. A rescuing party was at the scene of the explosion within 35 minutes after it occurred, and no one was overcome by gas, showing that the ventilation was good, and thus serving as an argument for the advantage of placing the magazine near a shaft.

The explosion occurred just at the time the shift was waiting to go to the surface for midnight supper. Had it occurred at any other time, few, if any, would have been killed.

The men on the 990-ft. station, 110 ft. above, report two explosions; the first one put out their lights, but was of no great violence. They lighted their candles and had started for another shaft, when the second explosion of great violence occurred, knocking them over, seriously injuring one, and slightly injuring three others. The explosion consisted of a shock, followed by concussion.

The skip-chute men who were loading the skips from chutes 45 ft. below the station were uninjured, and the men on the 1200 and 1300-ft. stations were uninjured. The explosion knocked out the posts of the station-set, which, with lagging and other timbers, formed a mass of débris, closing the shaft. Among the débris were recovered 22 bodies, and five injured men.

As ore was being hoisted from the 1100-ft. level the doors were down, closing the hoisting compartment below the skip-chutes. One body was found on these doors. The man-cage compartment was open, and eight bodies were recovered from below in this compartment of the shaft.

The stable, a light board shed, was entirely demolished, and here two bodies were recovered. The stable contained two horses, one of which was killed, while the other was uninjured.

Two bodies were recovered along the drift between the station and the shaft, and the fragments of at least one body were found in a corner of the magazine. I have absolutely no clew to the cause of the explosion and cannot account for it.

Relation Between Mineral and Chemical Industries.—I.

By George T. Holloway.

*In their highest state of purity, minerals are definite chemical compounds—chemicals as truly as the manufactured products—but made by natural processes. It is, in fact, now possible to manufacture a large number of 'minerals' by artificial means, such products being often so true to nature as to almost defy detection, and many being of commercial importance. It is true that, in nature, replacements are numerous, the composition of certain minerals being frequently varied and complicated by a partial substitution of one element for another without interfering with their crystalline habit, but the same applies to manufactured chemicals, as is well instanced in the case of the alums. Minerals also so commonly occur in admixture that, although the component minerals may be, and frequently are, chemically pure substances, they require to be separated in order that their respective commercial values may be realized. In the case of the majority of metalliferous minerals, mechanical 'dressing' or a preliminary metallurgical or chemical treatment is a necessity.

In the hope of being able to avoid the mere stringing together of a series of isolated facts, and to correlate such details as can be given in the time at my disposal, it is my intention to trace the formation of certain typical minerals from their primary igneous source, the molten magma or its solidified representatives, whose molecules, through natural agencies, have ultimately become rearranged into the forms familiar to the mineralogist.

In the production of mineral substances, the action of nature differs in no way from that of the chemist or metallurgist, but she has the advantage that her supply of raw material is unlimited, that her resources as to fuel, fluxes, and labor are unbounded, and that such details as time and balance-sheets are matters of indifference. Heat, water, air, and time are the principal factors through which her work is accomplished.

Our knowledge as to the composition of the earth is mainly confined to the examination of a thickness of the crust extending for less than fifteen miles from the top of the highest mountain to the lowest depths of the sea (but practically only of definite value for quite a small proportion even of this thin layer), out of the 4000 miles separating us from the centre of the earth. It is true that volcanic disturbances afford some clue to the conditions existing at greater depths, but the composition of the ejected material differs in no way, except in physical condition, from the deposits with which the mining man has to deal.

The fact that the density of the earth is about 5.5 (a little higher than that of magnetite) while the average density of the crust works out at rather over 2.6 (about the same as that of quartz, which is a distinctly light mineral), shows that the composition of the interior must be largely different, either generally or locally, from that of the crust.

Many attempts to estimate the relative proportions of the principal elementary constituents of the earth's crust have been made, the latest being that of F. W. Clarke, who in 1900 published figures based on analyses of 830 samples of the older crystalline rocks throughout the world and ignoring water and air. In 1898 and 1899, Professor J. H. L. Vogt, of Christiania, Norway, published an estimate, in which the rocks, air, and sea are included together.

The figures of Clarke and Vogt are as follows:

	Clarke, per cent.	Vogt, per cent.
Oxygen	47.02	50.00
Silicon	28.06	26.00
Hydrogen	0.17	0.90
Carbon	0.12	0.20
Phosphorus	0.09	0.08
Sulphur	0.07	0.06
Chlorine	0.01	0.17
Fluorine	0.01	0.03
Nitrogen	...	0.02
Aluminum	8.16	7.45
Iron	4.64	4.20
Calcium	3.50	3.25
Magnesium	2.62	2.35
Potassium	2.35	2.35
Sodium	2.63	2.40
Titanium	0.41	0.30
Manganese	0.07	0.07
Other elements	0.07	0.17
	100.00	100.00

It is interesting to note the great preponderance of non-metals over metals, the former constituting about 75% of the total, while aluminum, which by the mineralogist may almost be considered a non-metal, accounts for at least one-third of the remaining 25. The principal elements occur as oxides and the proportions in which such oxides exist have been calculated by Clarke as follows:

	Per cent.
Silica (SiO_2)	59.71
Alumina (Al_2O_3)	15.41
Ferric oxide (Fe_2O_3)	2.63
Ferrous oxide (FeO)	3.52
Lime (CaO)	4.90
Magnesia (MgO)	4.36
Potash (K_2O)	2.80
Soda (Na_2O)	3.55
Water (H_2O)	1.52
Titanic acid (TiO_2)	0.60
Phosphoric acid (P_2O_5)	0.22
	99.22

It will be observed that, with few exceptions, none of the ordinary metals of commerce are included in the above estimates, the proportions being far too small for individual mention. Even lead, with its annual production of about 1,000,000 tons, copper, with about 762,000 tons, zinc and tin, with their respective annual productions of over 724,000 and 108,000 tons, are all included among 'other elements', as also are the precious metals. It may be mentioned here that all figures throughout this paper are in tons of 2240 lb. Notwithstanding the fact that gold is almost as widely distributed as water and is the most sought after of all the metals, the 21,000,000 or 22,000,000 troy ounces of 'fine' gold extracted an-

*Abstract from Bulletin of the Institution of Mining & Metallurgy.

nually and valued at from £89,000,000 to £93,000,000, is in fact one of the least important of nature's products, when quantity is considered. It is probably produced at a loss, allowing for the expenditure on the unproductive enterprises of the gold-seeker. The ore from which this gold is obtained averages throughout the world under one-third of an ounce of precious metal, or, say, one part in 98,000, and amounts to well over 60,000,000 tons.

Apart from metalliferous veins which have filled fissures in the earth's crust from below, the primary source of most minerals is the fused or igneous matter which, by rapid cooling at the earth's surface, has yielded lava or the natural glasses, the latter being known as obsidian in the case of highly silicious matter, and by other names when more basic in composition. This fluid or semi-fluid igneous matter has often been acted upon by steam and other gases or vapors, and has thus given rise to vesicular and hair-like forms of lava, the former of which is known as pumice. When such igneous matters have been slowly cooled under pressure, as is the case with the deeper seated masses, such highly crystalline rocks as granite, syenite, diorite, and the like, or such semi-crystalline rocks as rhyolite, trachyte, andesite, and basalt have resulted, according to the rate of cooling. As with furnace slags, so in nature, rapid cooling tends to produce glassy products, and slower cooling the more stony or crystalline varieties.

Taken in mass, the natural glasses, having been produced from the same molten mass or magma, have the same composition as the corresponding semi or highly crystalline rock. During the slow cooling to which the latter have been subjected, however, aided often by the action of volcanic gases, steam, and other agencies, whose powers under the conditions existent are scarcely comparable with any of which we have actual experience, the minerals to which they owe their crystalline structure have separated. The more basic usually crystallize from the magma first, the order of separation being one of decreasing basicity, the quartz, which may be regarded as the excess of the acid constituent, silica, or that unused by the bases, crystallizing last of all, and commonly enclosing many of those minerals which were first formed. The partial solidification of a rock magma therefore usually results in the increased acidity of the remaining fluid portion, so that the composition of rock magmas may vary between highly acid and highly basic, and in classifying the igneous rocks, a transition from the vitreous to the crystalline state must be recognized, and a variation in chemical composition from highly acid to highly basic.

A concise classification of the igneous rocks is difficult, but for general purposes a tabulated statement such as Table I is convenient.

For my present purpose, it will be convenient to consider the crystalline igneous rocks as a whole, and Table II is intended to indicate the more important of the numerous products to which these rocks eventually give rise.

The most potent factors which result in the decomposition of rocks are air and moisture, aided by frost and the action of plants. Total submersion of a rock or mineral in water may, and commonly does, serve as a preventive to atmospheric action, but moist air has a power which few silicates and still fewer of the non-oxidized metalliferous minerals can resist.

The action of the organic acids produced from decaying vegetation and even the mechanical power of the roots of living plants, are also powerful disruptive and decomposing forces. These acids act as direct solvents, and they and other agents produced by the decomposition of plants are commonly powerful reducing agents, so that the insoluble peroxides in rocks and minerals become reduced to protoxides which pass into solution in combination with the organic acids or with carbonic acid. By this abstraction, red rocks are bleached, and the coherence of even compact stones is weakened until they crumble down to soil. The ferruginous solutions thus produced may, by oxidation, deposit their iron elsewhere.

At the depths and temperatures at which the rocks themselves were formed, silica is the most powerful of all acids. Practically non-volatile at temperatures at which most other acids evaporate or are decomposed, silica destroys or prevents the formation of compounds other than silicates until the affinities of the bases in the magma have become satisfied by it, any excess of silica separating out as quartz. A homely illustration is afforded by one of the most common of analytical processes—the fusion of silica or silicious matters with sodium carbonate. If quartz, the densest and most inert form of silica, be thus treated, carbonic acid is expelled with the formation of sodium silicate or 'water-glass'. If the latter be dissolved in water and treated with car-

bonic acid, carbonate of soda is re-formed, while the bulk of the silica is precipitated as gelatinous silicic acid (H_4SiO_4).

The action of carbonic acid in the natural decomposition of feldspars and of many other silicates of which the rocks are composed, is exactly similar, but the action is so slow that other factors intervene and the direct and complete decomposition explainable by formulae is thus often replaced by most complicated reactions resulting in the production of an immense variety of products, including clays, zeolites, and other minerals. But for the diluted condition of the attacking acid, the extremely dense nature of the crystalline silicates and the smallness of surface exposed to chemical action, decomposition would be effected far more rapidly than is actually the case.

So far as granite and many other igneous rocks are concerned, the chief decomposable constituent is the feldspar. There are many varieties of feldspar, the term being applied to a group of double, triple, or even more complicated silicates of aluminum and bases such as potash, soda, lime, or magnesia. These compounds occur in varying degrees of purity, and commonly merge one into the other, the potash variety, orthoclase, typical of granite, generally having a portion of the potash replaced by soda, lime, or magnesia, while the soda feldspar, albite, and the lime feldspar, anorthite, generally contain some bases other than the soda or lime which are their essential bases.

During the degradation of granite another of the principal constituents, the quartz, is also commonly transported (although to a less distance, on account of its coarseness) and ultimately reappears in such well known deposits as pebbles, gravel, and sand, containing also a large variety of other weather-resisting minerals which formed part of the original rock.

Such pebbly deposits, whether formed originally from granites or other rocks may, by the addition of clayey material or by the deposition of iron oxide, silica, carbonate of lime, etc., by percolating solutions, become eventually consolidated into conglomerate or pudding stone.

Should the percolating solutions be mineralized to any extent, or should the deposits become mineralized by any other means, commercially valuable products may be formed.

The well known 'banket' gold ore of the Transvaal affords an excellent example of this kind, immense beds of rounded quartz pebbles of varying dimensions having become compacted into hard rock. In this case the cementing material is mainly silica of a somewhat ferruginous character, the iron being oxidized above water-level but pyritic at depth. The origin of this material has been, and still is, the subject of much discussion, many interesting theories having been propounded to account for its formation and mineralization. It has been found that no gold exists in the pebbles themselves, all metal values being contained in the matrix or cementing material. The whole value of this, the most important group of gold-producing deposits, depends therefore on the secondary minerals through whose agency the gold was concentrated. Although throughout the Transvaal the ore non-treated averages under a third of an ounce per ton, the amount of fine gold produced there in 1908 was 7,054,621 oz., worth nearly £29,000,000, over one-third of the world's output.

As regards the soluble products from the decomposition of the igneous rocks, it is scarcely necessary to point out that many substances which are commonly considered insoluble, dissolve to a sufficient extent under conditions existent in nature, to produce most important commercial results.

Silica, in the form in which it is produced by the decomposition of silicates, dissolves in alkaline or practically neutral solutions. The deposition of silica from such solutions has resulted in the formation of flints, agates, jaspers, opals, and all varieties of chalcedony; of the petrified forests of Arizona and elsewhere, in which it has replaced the woody fibre of trees; and of the silicious terraces of New Zealand in the formation of which the silica has deposited from hot solutions almost as quickly, and in much the same manner, as carbonate of lime deposits from a 'petrifying spring'.

Vegetable and animal organisms also collect their tithe from dissolved silica and the enormous beds of kieselguhr or diatomaceous earth which are mined to the extent of thousands of tons annually for use as an abrasive, as a non-conductor, and as an absorbent in chemical industries, particularly in the manufacture of dynamite, consist of the outer shells or skeletons of fossilized minute infusoria, vegetable organisms which are remarkable for collecting silica to protect their tissue instead of the carbonate of lime which foraminifera and shellfish absorb, or the phosphate of lime which animals secrete.

The enormous use of quartz and other forms of silica in glass-making and for many other purposes, scarcely requires mention here. Quartz is one of the few minerals obtainable in quantity in a state of almost absolute purity, and reference may be made to its increasing use as the only source of silica glass, for the production of such important electric-furnace

products as elementary silicon and alloys of silicon with iron and copper, and of carborundum, alundum, and silundum, three carbides of silicon used as abrasives and for other purposes.

The solution of lime in carbonic acid during the decomposition of rocks and its reappearance as beds of limestone, marble, Mexican onyx, and other ornamental varieties, or as stalactitic deposits, or, after serving to build up the skeletons of foraminifera, corals, shellfish, etc., as chalk, and the like, is too well known to require more than passing mention, but it is worth while to point out that carbonate of lime, which has been collected from solution by such organisms, is thereby purified with formation of deposits of great purity.

Local or complete change of deposits of carbonate of lime has commonly occurred through infiltration of solutions containing sulphates, phosphates, and the like. This has resulted in the production of gypsum and other varieties of sulphate of lime, and of rock phosphate, the former minerals being used for ornamental purposes and in the production of plaster of paris, and the latter in the manufacture of chemical fertilizers. Some idea of the importance of these secondary mineral deposits, which are not of course all derived in this direct manner from carbonate of lime, may be gained from the fact that nearly 4,000,000 tons of gypsum is annually mined and that apatite and phosphate rock for manufacturing fertilizers, is mined to the extent of about 4,500,000 tons, of which the United States produces over half. The Atoll islands of the South Pacific Ocean, originally coral formations, are extraordinarily rich in phosphates, and deposits on two islands in the Gilbert group are stated to contain 50,000,000 tons suitable for export.

In the case of rocks less acid than granite, the weathering action, although essentially similar to that already described, results in the formation of larger quantities of the more basic products. In the basic rocks, the dark ferro-magnesian and aluminous silicates are in excess, and in decomposition, their peculiar products predominate, the distinctly magnesian ones yielding serpentine, while those more aluminous alter to chlorite, in either case with separation of such important minerals as iron oxide and carbonate, calcite, dolomite, magnesite, talc, asbestos, together with valuable accessory minerals such as chrome iron ore, magnetite, and possibly the oxidized nickel and cobalt ores which occur as double silicates with magnesia, in New Coledonia.

The important mineral, bauxite, a hydrated oxide of aluminum containing oxide of iron and other impurities, is a decomposition product of highly aluminous silicates. Opinions differ as to its exact mode of formation in many instances, but there is no doubt that processes similar to those already enumerated have played an important part in its production. The consumption of bauxite in the United States in 1907 was 122,841 tons valued at £171,770, and France, in the same year exported over 100,000 tons. About 60,000 tons of bauxite was consumed in 1907 for the production of about 32,000 tons of aluminum, but bauxite has many other uses.

Over 130,000,000 tons of iron ore varying in iron content from under 30 to nearly 70%, and averaging slightly under 40, is mined annually, the United States contributing considerably over a third of this total, and also supplying ore of higher average iron content than any other large producing country. The world's annual production of pig iron amounts to about 60,000,000 tons, Great Britain contributing about a fifth, and the United States nearly two and a half times as much. About four-fifths of the pig iron is converted into steel, and from first to last it is probable that well over 130,000,000 tons of fuel is consumed in mining and converting the iron ore into finished metal. By far the larger proportion of this fuel consists of coke made from bituminous coal. In the production of this coke, immense quantities of by-products, such as ammonia and ammonium sulphate, are produced, together with tar whose amount is now about equal in quantity to that produced in gas works and similar to it, although somewhat inferior in value. Waste gases, rich in combustible gas and intensely hot, as they leave the blast-furnace in which the pig iron is produced, are now no longer run to waste, but are employed for motive power to drive the whole plant, and I have seen, at Middlesbrough, the overplus employed for evaporating brine which has itself been raised from the strata below the works by pumps operated by engines driven by combustion of the waste-gases.

The manner in which one industry affects others, and in which each may depend upon the other for its success, could not indeed be better shown than in the case of the iron and steel industry. The direct effect on mining and on the chemical industries through the quantities of ore and fuel required and the immense amount of waste power and by-products resulting, is by no means the end of the tale.

The requirements of the steel-maker have resulted in an enormous use of ores containing manganese, chromium, and nickel, and the producers of such ores depend now more on this use than any other, and are able to dispose of ores which, when the chemist was practically the only purchaser, were unsalable, an ore which is utterly unsuitable for one purpose being often the best for another. In the case of manganese ores, pyrolusite or peroxide of manganese is practically the only one employed on a large scale by the chemist, while braunite, which may be described roughly as the sesqui-oxide, and others of the less highly oxidized ores, are preferred by the steel-maker and the producer of ferro-manganese and spiegel, who prefer as little available oxygen as possible. Lime is objectionable, but phosphorus harmless to the former, while to the metallurgist the position is exactly reversed.

It is worthy of note that over 100,000 tons of waste manganiferous residue from the roasting of franklinite and other zinc ore from New Jersey, were smelted for making spiegel and ferro-manganese in 1908, and that much of the true manganese ore which is smelted also contains zinc. So much zinc oxide is produced from blast-furnaces as to almost justify the installation of zinc retorts by the iron-masters.

A study of the manner in which certain minerals are usually found associated in nature; commonly

those which are isomorphous or which contain the same group of elements, but very often of entirely different mineralized and chemical character, is of particular importance to the commercial man, and should be of great assistance to such chemists and physicists as study the genesis of minerals and elements and the so-called degradation of the latter. Just as the Periodic Law of Newlands and Mendeléef was evolved from the tabular marshalling of chemical and physical data, and was found capable of prophetic use, so one may learn and predict much from a study of the known associations of minerals, and particularly those of the rare metals. There is the advantage of knowing that minerals have been produced under natural conditions where no mistakes or errors of manipulation can have occurred and where no difficulties due to want of time, material, or facilities for experimenting existed; in other words, where the personal factor was absolutely non-existent.

Probably the most promising field for research exists in the oldest plutonic rocks and particularly in such pegmatites and other extremely old granitic and other rocks as have been subjected at great depth and pressure and at high temperature, to the action of intruded flows of fused mineral matter from still deeper-seated sources, or of vaporized mineral matter of similar origin. Such rocks exist in many parts of the world, but the pegmatites of Norway, the old granites of Greenland, and many of the old but less highly crystalline tin-bearing deposits of Cornwall may be instanced as likely to throw light on the origin of many metals, and especially of those at the 'heavy' and 'light' ends of the periodic table.

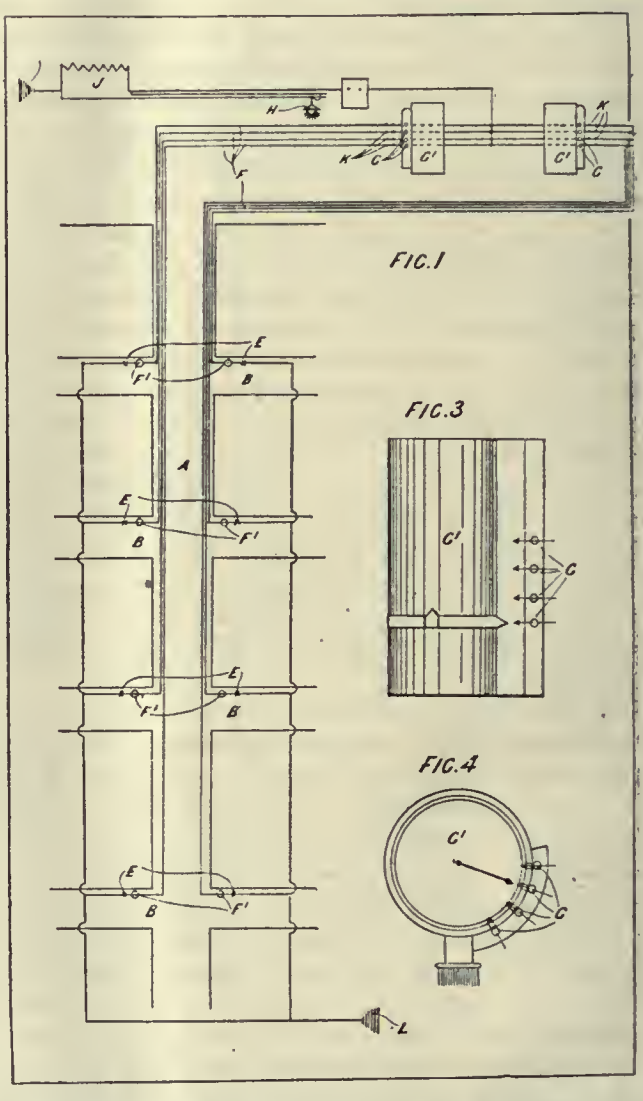
Improvements in design of steel mine timbers must go hand in hand with accurate knowledge as to the character of the loads to be sustained and the stresses produced in the material itself. Where the strata are horizontal, or approximately so, the loads are applied normal to the collar with a practically uniform distribution and produce therein bending moments, with compressive stresses in the legs, these stresses in the legs being equivalent to the half load on the beam, and the minimum amount of material is employed when the legs are exactly proportioned to this half load. Where the dip of the strata is great or where the ground is swelling, legs and collars may be called upon to take both bending and compressive stresses at the same time, and allowance must be made in the design for this joint action. In a vertical mine shaft through solid ground, the loads which need be borne will be not much greater than the weight of the lining itself, and stiffness and strength will only be required for the proper alignment of the cage guides. In heavy ground liable to displacement, or in an inclined shaft, the wall plates may be called upon to carry both bending and compressive stresses, and certainly the buntons will be called upon to sustain a large share of the load.

Calumet & Arizona has paid $10,600,000 in dividends on a capitalization of $2,000,000, par value $10 per share. The present dividend rate is $4 per share, but the company is earning more. The stock sold as high as $184 in 1906.

Electric Signals in Shafts.

By W. E. Wainwright.

*Several serious accidents, which had occurred owing to the station or 'plat-man' leaving the plat without first withdrawing the 'chairs' from the shaft, set me scheming to devise a mechanically operated system which would obviate such accidents and be 'fool-proof'. It was obvious at the outset that some means of indicating to the engineer by the movement of the chairs themselves, whether they were 'in' or 'out' of the shaft, was necessary. An arrangement for signaling similar to railway semaphores was



considered, but was rejected owing to the difficulties accruing from the large number of communicating wires which would be required down the shaft—two for each level. After several experiments, a comparatively simple and efficient electrical system was devised, and which is covered by Commonwealth Patent No. 10,402. One of the chief features of the apparatus is its simplicity, and its strongest point is the fact that both the engineer and plat-man receive visual indication of the position of the chairs.

The arrangement consists of miniature colored glow lamps, one for each level of each shaft compartment, arranged and placed beside numbers and arrows corresponding to the various levels, on the hoist-engine indicators. There is also a large indi-

*Abstract from *Trans.* Aust. Inst. Min. Eng.

cating glow lamp installed at each compartment at the various levels, in proximity to the levers for operating the chairs. Upon moving the levers an electrical current is completed which instantly indicates in the engine room by the glowing or extinction of the corresponding miniature lamp, the position of the chairs. The large glow lamp at the underground station indicates in unison with the small lamp on the engine indicator, giving ocular notice of the position of the chairs to the man operating them, and is a visual reminder not to leave the plat without withdrawing the chairs. The plat and engine indicator lamps are arranged in series, so that one cannot illuminate without the other, a defect in one causing

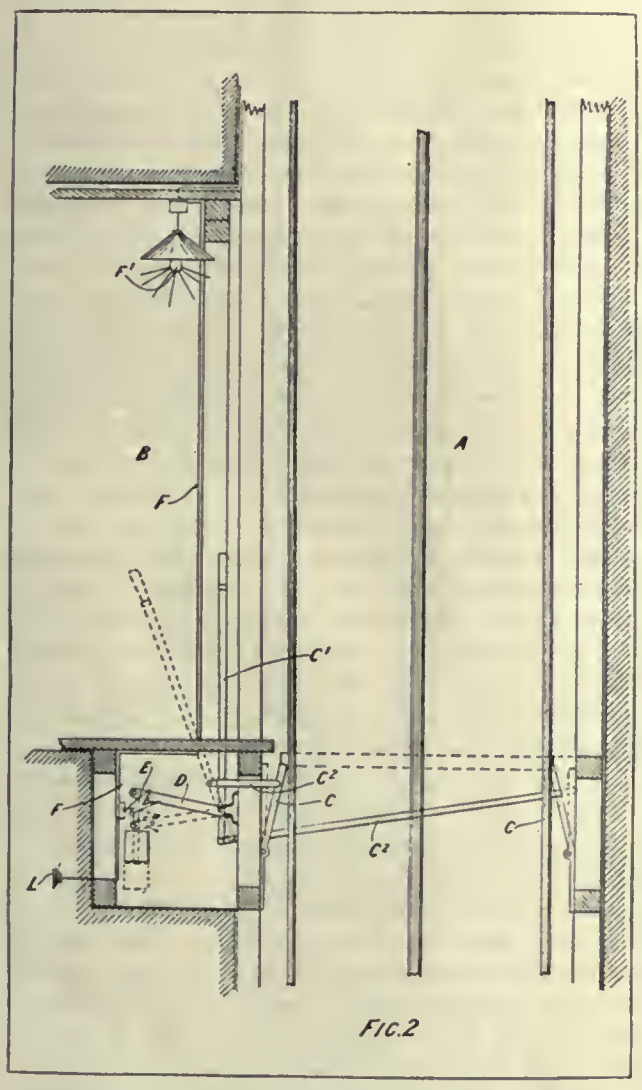


FIG. 2

non-illumination of both lamps. This arrangement is a safeguard, as the glowing of the plat lamp indicates the recording of a similar signal on the winding engine indicator.

By reference to the diagrams (Fig. 1, 2, 3, and 4), the arrangement of the equipment will be readily understood. Fig. 1 represents a two-compartment mine shaft with four plats. Fig. 2 represents a side section of shaft and plat at one of the levels, showing the connection with the chairs. Fig. 3 and 4 are detailed views of drum and dial indicators, showing position of the miniature indicating lamps at winding engine. A is the shaft, and B, B, B, B, the four plats at which chairs C are arranged for operation by the lever C^1, and connecting rods C^2. An arm D, engaging with an electric switch E, operates a circuit F, which causes a current to pass through the indicating glow lamp F^1 in the plat, and thence through the circuit F passes through the miniature indicating glow lamp G, arranged opposite the arrows and pointer for the various levels on the winding engine indicator G^1.

Upon the plat-man operating any of the chairs at the various levels, the large glow lamp for the corresponding compartment immediately glows, and thereby informs him that the engineer has notification of the chairs being in at such level and compartment. A further casual advantage is afforded by the increased illumination at the plat from the glowing lamp, when the chairs are in for loading or unloading the cages. A pilot lamp H, in Fig. 1, arranged to glow at a low temperature, and placed in direct view of the hoisting engineer, is advisable, as the extinction of this gives immediate notification of any failure of the current from the source of supply to the indicator circuits. The current for operating these lamps may be taken from any convenient lighting circuit at 50 to 120 volts, and is shown in Fig. 1 at J, which represents the secondary of a transformer operated by alternating current; the latter is preferable for damp or wet shafts, but a common return is preferable to an earth return in cases where telephones are installed in the same shaft. The estimated cost of installing the apparatus in a double compartment shaft of six levels is approximately £75.

Investigations made by the United States Geological Survey have disclosed the fact that the total cost of fires in the United States in 1907 amounted to almost one-half the cost of new buildings constructed in the country for the year. The total cost of the fires, excluding that of forest fires and marine losses, but including excess cost of fire protection due to bad construction and excess premiums over insurance paid, amounted to over $456,485,000, a tax on the people exceeding the total value of the gold, silver, copper, and petroleum produced in the United States in that year. The cost of building construction in forty-nine leading cities of the United States reporting a total population of less than 18,000,000 amounted, in 1907, to $661,076,286, and the cost of building construction for the entire country in the same year is conservatively estimated at $1,000,000,000. Thus it will be seen that nearly one-half the value of all the new buildings constructed within one year is destroyed by fire. The total fire cost in this country is five times as much per capita as in any country of Europe. The first cost was greater than the value of the real property and improvements in ony one of the following States: Maine, West Virginia, North Carolina, North Dakota, South Dakota, Alabama, Louisiana, Montana. The actual fire losses due to the destruction of buildings and their contents amounted to $215,084,709, a per capita loss for the United States of $2.51. The per capita losses in the cities of the six leading European countries amounted to but 33c., or about one-eighth of the per capita loss sustained in the United States. In addition to this waste of wealth and natural resources, 1449 persons were killed and 5654 were injured in fires.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Slime Concentration.

The Editor:

Sir—I desire to continue the subject of 'Slime Concentration' introduced last July in your 'Discussion' department, commenting upon the relatively low efficiencies maintained by belt and table concentrators, and consider the possibility of constructing a modification of one or the other which should be capable of universal application or at least beneficial in individual cases. It is but natural to look to the manufacturers of concentrating machinery for help in this direction, but they seem to be so enthusiastically engaged in developing their respective machines from a commercial standpoint that but little attention is given to improving the working principles. Yet I may say here, that as much as ten years ago, John W. Nesmith introduced a successful system of concentration which today is practically unknown in the gold-producing counties of California where milling and concentrating is practised so extensively. Along the Mother Lode, and especially in Nevada and Sierra counties, the concentrates are all obtained by belts and canvas tables and there are no vibratory tables save in a few cases. These have there been rejected after brief periods of trial. It is not my intent to criticise milling or concentrating practices in California, but to endeavor to show the defects in existing machines, and to suggest reasonable remedies, and to emphasize Mr. Nesmith's sound advice: 'avoid slime-losses; don't make slimes'.

There are individual particles of sulphides that will not settle owing to their physical structure, such as thin scales which float buoyantly; finely ground mineral which floats in moving water, but would settle immediately in quiet water; particles which will settle to the belt but do not develop friction to cause adhesion to the belt and withstand the sluicing action of the stream. Other particles settle upon the belt midway between the distributer and the discharge, and the attendant having been instructed to save the mineral clean, permits that percentage of mineral to escape by using too much clear water.

In the case of highly mineralized ore, when a certain percentage of mineral settles to the belt it finds the surface already occupied by other particles, and is then sluiced off with the rest of the pulp. Also, there is quite a percentage of mineral which gets past the pulp-distributer to the space between the pulp and clear-water distributers, where it is exposed to the action of the clear water and is washed away with but little chance of returning.

I have watched concentrating tables for hours, studying their behavior with a powerful glass, and I can testify that the loss from this one cause is considerable. At times I have been able to check this loss by using one and sometimes two clear-water distributers, made as follows: a piece of 2-in. pipe as long as the width of the vanner and perforated with $^1/_{16}$-in. holes, 1 in. apart. The last holes at each end were swaged a little to compensate for excess material next the lip. Water connections were made through reducers from 2 to ½ in. at each end, and both fed from a single valve, centered above and connected with a small suspended reservoir having its inlet protected by a piece of 30-mesh screen to prevent the holes in the distributer from choking. This style of distributer admits of being secured to the frame, and may oscillate with the belt, provided a short length of hose be used to connect it with the clear-water valve. Its chief value lies in distributing an even film of clear water without splashing or channeling, and the water being under pressure at both receiving ends, a much more uniform distribution is effected. Care must be exercised in boring and reaming the holes, as ragged edged holes cause trouble.

Having ascertained the losses, the next consideration should be, how can some of these losses be avoided? For the purpose of illustration, let one of the so-called 'free-milling and concentrating' properties in California, equipped with a 20-stamp mill, vanners, and canvas tables, be the object of investigation. Begin by carefully panning and re-panning the tailing below the vanners, noting and recording the physical characteristics of the minerals forming the concentrate so panned, and also the middling. Recover 4 oz. of fairly clean mineral and middling from average samples of tailing and then prepare a rubber pan as follows: cut a disk of rubber from an old vanner-belt free from pits or cracks, of a diameter which will snugly fit into a gold-pan from the bottom up the sides to within 1 in. of the rim; then take the pan and bore a dozen holes ⅛ in. diam. equidistant around the side of the pan and about 2½ in. below the beveled rim; next punch a series of holes in the rubber disk to correspond with those in the pan. A bucketful of water on the disk in the pan answers very well as a weight to hold it firmly in position while the holes are being punched. As each hole is punched it should be riveted, using copper rivets and washer, swaged on the outside of the pan. Be careful that the bottom is smooth and tight. Take half of the sample of concentrate, throw it into the pan, and cover with clean water to a depth of ¼ in. or less, and agitate briskly and then 'corner' suddenly, noting whether the middling hugs close to the cornered mineral or lags behind; next agitate slowly and regularly, 'corner', and again note the position of the clean mineral and the middling. If there is no clean mineral in the corner no further experiment need be tried, but if clean mineral appears, proceed further by holding the pan nearly level in the left arm, and vibrate by striking gently with the right hand, imparting a horizontal motion and allowing a recoil by keeping the left arm rigid, repeating these movements rapidly until the clean mineral and middling have stratified over the bottom in an even film, showing lines of demarkation reasonably clear. Then, still keeping the stratification wet by gently tipping the pan so that they remain saturated but not disturbed, have an assistant introduce a small flow of clear water, equal to one of the graduations on the clear-water distributer of the vanners, letting it down

into the pan identically as in actual practice, and note the amount of mineral that withstands this flow. At this point, as a rule, inspirations are born. The interested observer generally discovers his clear-water distributers to be too high above the belt. Anyway, whatever shows in the pan to have resisted the flow is precisely what will be saved in practice. Further proof of the vanner's ability to save more under certain conditions may be obtained by roughly panning down 250 lb. of tailing and dyeing the concentrate resulting therefrom a readily distinguishable color, and after drying throw the same into a launder leading to a vanner and then watch the cleaning-space which will presently show an appreciable quantity of the dyed mineral. In any event the experiment with the pan will govern the next step, which is to set up and put in first-class working order a spare vanner of any convenient size and deliver to it half the tailing from one of the other operating machines. With the pulp flowing freely, and all adjustments in working order, notice that the vanner is saving a small amount of mineral. An effort is made to save this by reducing the inclination a degree at a time, until, having cut the fall in half as compared with the other machines, the pulp barely discharges. At this point commence to add clear water to the launder feeding the pulp, diluting it until the pulp discharges as freely as on its more steeply inclined companions, simultaneously reducing the speed a little at a time and increasing the oscillations a few strokes per minute until in appearance the machine is loaded like its neighbors and is saving just as much in proportion. It will, however, have the advantage that the pulp remains on the belt nearly twice as long, affording time for the mineral to settle. Fully 60% of what had been found in the pan will be saved clean, and 15% more, if a small quantity of middling and coarse gangue be allowed to come through with the mineral.

FRANK R. PORTER.

Blair, Nevada, January 23.

Modern Quicksilver Reduction.

The Editor:

Sir—Replying to H. W. Turner's letter appearing in your issue of November 20, his correction that "the soot is formed in the condenser" is timely as well as self-evident. Regarding the percentage of mercury recovered as pure metal and from the soot, the statement quoted from Spirek ("only 6.5% of the total production being recovered from the soot" at Monte Amiata), does not agree with Schnabel, who states, in Vol. II, 'Handbook of Metallurgy' (Ed. 1907), page 341, that "thus at Monte Amiata only 20 to 30% of the mercury is got in the form of the metal—the rest is converted into 'stupp';" on page 430, he states that "recently at Idria, of the total production of mercury, including a loss of 9%, 56% was obtained by pressing the soot and 15% by distillation of soot residues;" on page 435 he states that, "according to recent communications from Mitter, in Idria, the extraction of mercury is at present distributed as follows: metallic mercury taken direct from the condensers 20%," and then follow the figures quoted on page 430. It is evident from the above that there is considerable difference of opinion among those who are authorities. The high extraction made in California, 70% of the total mercury being recovered as pure metal from the condensers, is excellent work as well as interesting information.

LESTER W. STRAUSS.

Lima, Peru, December 20.

The Editor:

Sir—Concerning the disagreement in the statements of Schnabel and Spirek as to the amount of free metal obtained in the Monte Amiata quicksilver furnaces, quoted by Mr. Strauss, it may be noted that Spirek was the metallurgist in charge of these furnaces during the period reported on by him, and should have known absolutely all the details of the recovery of mercury.

H. W. TURNER.

San Francisco, January 13.

Dredging in Montana and Idaho.

The Editor:

Sir—In the article on 'Dredging in Montana and Idaho' in your excellent annual number (January 1, 1910), I am quoted as authority for the statement that "N. S. Shaler was responsible for tests which proved the portion of Ruby valley that receives the wash from Alder gulch to be profitable dredging ground." This statement is too broad, and owing to the respect given to articles in your paper, it may lead to an erroneous impression. The success of the Ruby valley dredging field has attracted attention to the development of that enterprise, and as the property holds a unique position in gold dredging annals, the profession is interested in more accurate historic details.

It was in 1896 that the first steps were taken to prove the value of the area below Alder gulch for machine-mining. J. C. Sloss, a well known and experienced placer-miner, superintended the preliminary explorations by test-shafts and drilling with Keystone drills. The general recognition, acquisition, and early development of the property were due to P. N. Moore who had charge of the engineering features and to the late H. G. Bixby who looked after the business side. Although Mr. Shaler was a business associate, and was familiar with the situation, he did not see the property until after the exploration and acquisition by the syndicate of which all the gentlemen named were members. The history of this enterprise, particularly from an engineering point of view, is highly interesting to those engaged in auriferous gravel mining. The struggle for success has been of great educational value to the profession, and perhaps all the better modern machines embody in some details the mechanical improvements evolved, particularly in the bucket-line and in the practice for cold-weather operating.

A. H. WISEMAN.

Seattle, March 1.

Tungsten salts are used in fireproofing cloth for curtains and draperies; in weighing silks; in glass making; as a mordant in dyeing; and for other purposes.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Excavation in earth by a 90-ton steam-shovel should average about 18 cu. yd. per hour.

Maximum length of drill-steel for open rock-work, drilling deep holes, may be as great as 20 feet.

Pile-heads immediately upon being cut should be coated with hot asphaltum thinned with creosote oil.

The Federal mining law does not extend to Texas, the Philippines, Porto Rico, nor the Hawaiian Islands.

Asphaltum should be applied to all cut surfaces of creosoted timbers, when fitting and setting up, either in framed structures or in mine timbering.

Creosoted timber twenty years old has been found by tests in testing machines to be as strong as newly treated timber.

Leading-hose for conducting compressed air to the upper bench in driving the Bergen Hill tunnel of the Pennsylvania railroad was of rubber and cotton, covered with woven marlin, 3 in. outside diameter.

Powder consumption at the Alaska Treadwell mines averages 2 lb. per ton. This is slightly in excess of the usual amount, due to the character of the ore, which is hard and tenacious.

Eight elements only are of special interest as regards quantity in the earth's crust. Of the others the proportions are so small that probably few exceed 0.01 per cent.

Placer locations are required to conform as nearly as practicable to the rectangular system of the public surveys, so as to prevent 'shoe-string' locations. The ideal lode-location is in the shape of a parallelogram. A placer claim should be square in form even when within unsurveyed land.

Actual work in the removal of gravel for extraction of the metallic content, the sinking of shafts, or the installation of mining equipment for operating a placer claim, is the character of improvement contemplated by law as performance of annual labor to hold title.

Alumina in excess in a charge for copper smelting requires generally an increase in temperature, and leads to conditions favoring the reduction of iron to the metallic form, causing serious difficulties in smelting. In rare cases slags containing as much as 24% Al_2O_3 have been successfully smelted.

Annual labor on an association placer-claim of 160 acres, as required by law, is the same as for an individual claim of 20 acres, namely, the equivalent of $100 worth. Work done in good faith to operate or explore a deposit, whether productive of a profit or not, is acceptable, so long as it is done to benefit the claim.

Steel used in drilling the new tunnels for the Pennsylvania railroad through the diabase mass of Bergen Hill, New Jersey, including that lost and scrapped, was almost exactly 1 ft. for each 10 cu. yd. of excavation, or 1¼ in. per cubic yard. The loss due to sharpening was from ¾ to ⅞ in. per cu. yd., that work being done with an 'Ajax' sharpener.

Inspection was formerly relied on in steam-boiler practice to maintain them in condition. It is still wise to make periodical investigation of the internal condition of boilers, but the true way to get the best results is not to allow mud and scale to accumulate inside, but to remove all such impurities from the water before it enters the boiler. The best way to keep a boiler clean is to put only pure water into it.

Grouting the surface of concrete in order to make it smooth, leaves it subject to unequal wear, owing to the lack of uniformity in the degree of hardness in such a thin layer of cement. The 'set' of a thin sheet of cement is not the same as that of a larger mass. For this reason the tops of concrete blocks for setting heavy machinery should not be made 'true' by grouting, but by dressing down after the block has set, in the same way as the surface of a stone would be finished.

Launders should not be made of concrete. Such launders cut rapidly under the abrasion due to mill-pulp. Steel and iron abrade still more rapidly. Concrete lined with wood makes a good launder. The softer woods are better for this purpose than hard woods, but 'clear' stock should be selected. In the Garfield mill of the Boston Consolidated Copper Co. (now absorbed into the Utah Copper Co.) concrete launders lined with plate-glass are employed, and the wear is reported to be inappreciable after two years' service.

Disruptive power of frost is merely physical. Its shattering force is comparable with the grinding of ore in a mill prior to its chemical treatment, although its effect is limited to a large extent by the physical condition of the mineral itself. One mass of rock or mineral may be comparatively unaffected, while an adjacent deposit, of practically the same mineralogical composition, may be completely disintegrated and decomposed, merely on account of the physical condition of the latter being favorable to the entry of films of water between the crystals or interspaces, or into fissures or cracks.

Titanium, which is usually regarded as one of the rarer elements, occurs in greater proportion than most of the commercial metals, but it must be remembered that most rocks and most aluminous minerals contain titanium either as an accessory mineral or as an impurity, although true titanium minerals such as rutile, ilmenite, and the like, are comparatively rare. The proportion existing in the earth's crust is, however, no criterion as to the amount of an element commercially available. Iron, for example, is present in the crust to the extent of over 4½%, but the great bulk exists, as in the case of titanium and aluminum, only in the rock-matter or in other forms not available for use.

Special Correspondence.

CAMBORNE, CORNWALL.

Tin Mining.—South Crofty Pays Dividend.—Carn Brea and Tincroft Ore Poorer.—Dolcoath Report.—Wheal Vor.—National Minerals Promotions.

It is pleasant to be able to record that South Crofty has joined the list of dividend payers. This mine is close to Dolcoath and in days gone by was worked for tin under the guidance of practically the same people as Dolcoath. Owing to the high content of wolfram and arsenic, and also to shortness of capital, operations came practically to a standstill. In 1906 during the boom in tin, the Allen-Meyerstein group in London came forward and provided new capital for reorganizing the mine and the plant. The old cost-book company was transformed into a limited liability company with a capital of £50,000. On flotation the vendors received 20,000 shares credited 15s. paid with a liability of 5s., and the promoters subscribed for 20,000 shares at par. In 1907 and 1908 the remaining 10,000 shares were issued at £4 per share. The total cash capital subscribed was therefore £65,000. The company has sunk a new shaft and has by instalments provided 60 stamps, together with tables and magnetic separators. For some time the mine has been paying its way, and for the year 1909 a dividend of 3s. per share has been distributed. The report for the year 1909 shows that the production was 696 tons of tin concentrate valued at £53,481, 142 tons of wolfram valued at £12,462, and 666 tons of arsenic valued at £6950. The actual receipts during the year from sales were slightly different from the value of the production, being £52,669, £13,939, and £7443 respectively, making a total income of £74,223. The cost of mining and dressing was £58,469, and London expenses came to £1105. The amount written off for depreciation of buildings and plant was £3266, and the balance of profit for the year was £10,791. Out of this amount £7500 has been paid as dividend and £2738 written off for development. The average extraction was 26.28 lb. of tin concentrate per ton, 5.38 lb. of wolfram, and 25 lb. of arsenic, these figures all show an increased extraction over the previous year when the corresponding figures were 23.8 lb., 5.18 lb., and 21.3 lb. The total value of the produce per ton was 24s. 7d. and the mine cost was 19s. 5d., as compared with 22s. 2d. and 20s. 11d. respectively in 1908. The mine has now been unwatered to the 225-fathom level and the new main shaft is nearly to that depth. When sinking is completed to that level unwatering and sinking will be continued for another 20 fathoms. During the year the company has completed the arsenic refining works and the output is sold well in advance. The last unit of 20 stamps out of the 60 came into operation at the beginning of the year. Other recent additions have been made to dressing plant, including an additional Buss table, four Frue vanners, and three slime tables.

In writing of Carn Brea and Tincroft six months ago I expressed a hope that the increased energy of the management would place this company on a permanently sound footing. The mine is a neighbor of Dolcoath and South Crofty and is the second largest producer of tin in Cornwall. Unfortunately the grade of ore has fallen off and the results for the second half of 1909 have not been so favorable. Though the ore treated is larger than ever before, being 37,813 tons, as compared with 34,790 during the second half of 1908, and 36,825 tons during the first half of 1909, the extraction has only been 29.52 lb. of tin concentrate per ton, as compared with 34.55 lb. during the previous half-year. Consequently, though the average price per ton has increased to £72, as compared with £69, the total income has been only £35,888, as compared with £39,428. Other small items of income from arsenic and copper ores brought the total income to £39,006. Against this the mining expenses were £41,266 and the lord's dues £1398, leaving a loss on the year's operations of £3657. The cost per ton of ore treated was 22s. 7d. Development work has about kept pace with the extraction, and it does not appear probable that the current year's operations will show any marked improvement.

Dolcoath did not do so well during the second half of 1909 as during the first. In the earlier part of the year richer ore was mined with the express object of employing less labor, which could therefore be transferred to development. It is not altogether a surprise therefore to find that the output of tin concentrate has diminished by 97 tons. The output of ore was 46,349 tons of ore and 903 tons of concentrate was produced. In August last I recorded that the produce during the first half-year was 1000 tons, and mentioned that this figure had not been reached since 1901. The produce during the second half of the year was 43.68 lb. per ton, as compared with 48.85 during the first half, but nevertheless, with this exception, it is the highest yield per ton since 1901. The average price per ton was £82 6s. 6d., as compared with £79 16s. 4d., and the total receipts £74,411, as compared with £79,864. Other items brought the total income for the half-year to £75,854. Against this the total cost was £63,132, including royalties of £4960, leaving a profit of £12,722, out of which £3203 was allowed for depreciation, and £8500 distributed as dividend, which is at the rate of 5% per annum on the capital, £350,000. The new main shaft is now down 2832 ft. from the surface, as reported in your columns at the time connection was made at the 440-fathom level between the present workings and the new shaft, in September last.

The Cornish mine known as Wheal Vor was re-opened in 1906 by the Dolcoath people. It is situated in the Breage district of Cornwall and in years gone by was a large producer. The work of re-opening has so far been confined to unwatering and clearing the shafts and levels, and it has been delayed by the unsuitability of the electric pumps provided at first. R. Arthur Thomas, the consulting engineer, reports that the present installation of electric pumps is working satisfactorily and that the mine is now unwatered to the 144-fathom level. The various levels have been explored and cleared, and some development has been done by tributors. Tin-bearing veins have been found at a number of places, and a substantial one averaging 30 lb. of black tin per ton is receiving attention. A significant remark made by Mr. Thomas recently was this: "It is no use disguising the fact that from the examination of the workings we find that the old men have been there before." More money is wanted to continue the work. The nominal capital of the company is £90,000, divided into 120,000 ordinary shares of 10s. each and 60,000 priority shares of like value. Of these all the ordinary and 24,000 of the priority have been issued. Of the ordinary 24,000 were issued, credited as fully paid, in payment of the purchase of the lease, and 96,000 were subscribed in cash on flotation to provide working capital. There are many overdue calls on the ordinary shares outstanding, and great difficulty is experienced in making shareholders pay. The priority shares were created in June of last year when funds ran short. Of the issue of 60,000 only 24,000 were taken and 2s. 6d. per 10s. share has been paid upon them. Certain London brokers have signified their willingness to underwrite the remaining 36,000 if they get any encouragement by local shareholders showing some disposition to subscribe for some of them.

I have from time to time referred to the doings of the London promoting firm known as the National Minerals Corporation in Cornwall in connection with the Falmouth Consolidated, St. Ives Consolidated, and St. Agnes Consolidated. The Corporation does not now issue the reports of its companies to the press; at least the yearly report of Falmouth Consolidated has not been issued. This company owns the Wheal Jane group of old mines between Truro and Chacewater, and I have already recorded how ball-mills were first installed and then thrown out, and stamps substituted. The stamps are now ready to start work and the chairman of the company recently announced that they should be in operation by March 1. It is nearly a year since the ball-mills were ejected, and the reason for the delay in getting the stamps ready is not quite clear. The chairman says the blame must be thrown on the weather. Fancy saying of any place in Cornwall: "In wintery weather this is a very boisterous place, and during the past few months the gales have been such as to render work on the surface, except at odd times, extremely difficult and painfully slow."

I do not know what the champions of the so-called 'Cornish Riviera' will say to this. My remarks in a recent issue about the exaggerated claims of Cornwall as a winter health resort brought hornets round my ears, but I never said anything half as bad as this. As regards the ore reserve, the chairman has indulged in even wilder and more ludicrous statements. Instead of giving a detailed account of the known, probable, and possible ore, he says that "in the opinion of the company's engineers the mine is of sufficient capacity to eventually keep supplied 500 or even as many as 1000 stamps." Most mining engineers had hoped that public opinion had been educated sufficiently during recent years to refuse to listen to such Whitaker Wright statements, and the profession generally is sorry that such methods are still in existence. Another point in connection with the methods of finance pursued by this corporation should be mentioned. In floating the Falmouth Consolidated the promoters received £75,000 in shares, £5000 cash, and an option over 20,000 more shares at par. This was out of a capital of £150,000, of which £44,683 were subscribed by the public. What did the promoters do to earn this preponderating interest? Nothing but transfer the leases of the properties to the new company and do a little hauling by horse-whim. The properties belong to Lord Falmouth and others, and are held on 21-year leases at a rental merging into royalties. In the prospectus the astonishing statement is made that nothing is being paid for goodwill. As a matter of fact there is no goodwill in an abandoned mine. But what was that £75,000 in shares paid for anyway?

WASHINGTON.

Alaskan Coal.—Reservation and Leasing Proposed.

A reasonable estimate of the value of the mineral wealth of Alaska is wanted in Washington just now. Representatives of the Guggenheim-Morgan syndicate, who appeared before the Senate Committee on Territories several days ago, gave startling figures. Their statements, made with the avowed purpose of counteracting the influence of muck-raking magazines, created more of a sensation in political Washington than any of the stories that had appeared in the magazines themselves. It left Congress in confusion. Mr. Beveridge, chairman of the committee, rallied and introduced two bills in the Senate. The first provides that all deposits of coal, lignite, and associated materials in the lands of the United States within the District of Alaska shall be withdrawn from location, entry, or sale and reserved for future disposition by Congress; provided, that the surface of such lands and other mineral deposits therein may be taken up and title thereto acquired under the laws that would be applicable thereto if this act had not been passed; and provided further, that all patents for lands hereafter taken up in this district shall expressly reserve to the United States and its lessees all deposits of coal, lignite, and associated mineral in the lands patented, and the right to use so much of the surface as may be necessary in the mining thereof. The second bill provides that all deposits of coal, lignite, and associated minerals, belonging to the United States in the District of Alaska, with the right to use so much of the surface as may be necessary in the mining thereof, shall be disposed of only by lease, under such rules and regulations and upon such terms and conditions as the Secretary of the Interior may prescribe; provided, that no lease shall be made to any one person, association, or corporation, of deposits underlying a greater area than 2560 acres, nor for a longer term than thirty years; nor shall any such lease be assigned or otherwise disposed of except by the express permission of the Secretary of the Interior; and all such leases shall be reported to Congress at the beginning of the first session following the granting of such leases.

Mr. Beveridge gave his estimate of the value of Alaska in the following language: The Geological Survey estimates that in all the coalfields now known there is a tonnage of 15,104,500,000 tons, that the areas known to be underlain with coal aggregate 1202 sq. mi., and that the present known coalfields aggregate an area of the enormous sum of 12,867 sq. mi. That, upon the basis of the testimony of the manager of the Alaska syndicate before our committee, would run the money value of the now known coalfields in Alaska into many billions.

DENVER, COLORADO.

Mining at Cripple Creek. — Proposed Asbestos Merger. — Coal Mine Inspector's Report. — Decision of the Inter-State Commerce Commission.

Mining operators in the Cripple Creek district were especially busy during February. The production for this, the shortest month of the year, was $1,206,527. The grade of ore averaged $22.81, which is slightly above the usual figure. Many leases have been granted during the month, and several rich finds made by lessees and by companies. The Deep Drainage tunnel advanced 259 ft., making a total distance of 12,604 ft. from the portal. The Elkton and Pharmacist companies paid dividends amounting to $37,500 and $7500 respectively. This brings the total of announced dividends up to $150,000 since the first of the year. It does not indicate, however, the profits made by lessees or by close corporations. On February 26 the properties of the Keystone Mining & Milling Co. and the Ida May Gold Mining Co. were sold by the sheriff under writs of execution issued by the district court of El Paso county. The Keystone properties were bid in by Horace G. Lunt on a judgment of $9858. The Colorado Title & Trust Co. secured the Ida May properties on a debt of $3437. James F. Burns has filed a petition in district court asking for a receiver for the Magnet Rock Mining Co., whose principal property is the Monte Cristo lode claim at Cripple Creek. He alleges that the company has held no stockholders meeting since 1906, and that since the officers, with the exception of the secretary, are out of the State he cannot examine the books. The Petrel Gold Mining & Milling Co. has recently been incorporated under the laws of Wyoming, to operate the properties of the Papoose Gold Mining Co. situated on Squaw mountain, besides other territory acquired by the new company amounting in all to about 30 acres.

There appears to be a movement on foot to form an asbestos trust. Representatives of the Amalgamated Asbestos Corporation of Canada have been examining the large deposits near Casper, Wyoming, and an offer, it is said, of a million dollars has been made for the control of this deposit covering about 1200 acres. The United States Asbestos Mining & Fiberizing Co. of Berkeley, California, and the International Asbestos Co., North American Asbestos Co., and the Wyoming Consolidated Asbestos Co., all of Casper, Wyoming, are interested in the merger. The organization of such a company would control 90% of the asbestos production of the world.

The report of the State coal mine inspector relative to the Primero mine disaster of January 31 has been handed to the Governor. The report holds the Colorado Fuel & Iron Co. responsible for the 76 lives lost in the explosion. The inspector holds that the company neglected to sprinkle the mine as required by law. Because of the excessive amount of coal dust in circulation the explosion extended throughout the mine, whereas it would have been only local had the mine been properly sprinkled. The report recommends that a law be passed by the legislature prohibiting miners, other than shot-firers, from taking powder, matches, or explosives of any kind into a coal mine. The United Mine Workers of America have also investigated the cause of the explosion. The report of their committee to the president of the organization charges the coal mine inspector and his deputy with allowing the company to violate the law. It might be urged at this point that the number of deputy inspectors be increased so that the mines could be properly inspected at frequent intervals, and that each inspector be made responsible for a certain number of mines. It is a physical impossibility for the present force of inspectors to do the work expected of them in anything like a thorough manner.

The Interstate Commerce Commission has recently handed down a decision that is of interest to all mining men in Colorado. The decision establishes joint rates from the Walsenburg coal district in Colorado to points in Texas, Kansas, and New Mexico. Heretofore the through rates

have been prohibitory. Under the law, a satisfactory through rate is required if demanded by the shippers. The Cedar Hill Coal & Coke Co. was the complainant to test the law. Strong opposition was put forth by the railroads affected.

GOLDFIELD, NEVADA.

Goldfield Con. Ore-Shoots.—Florence Goldfield Improvements.

The Consolidated Goldfield Mines Co. is mining and milling 300 tons of ore per day from its Clermont workings and 200 per day each from the Mohawk, Red Top, and Combination. The four shafts are sunk from 1000 to 1500 ft. apart along the north strike of the ore-bearing zone, which has an approximate length of 6000 ft. and a maximum width of 2000 ft. The orebodies in this zone, which occur in shoots and lenses, have usually a dip northeast, the gangue being a quartz and silicified dacite. In the Clermont shaft shoots of ore have been opened on all the levels. The ore-shoot on the 600-ft. level is 170 ft. long, and has an average width of 15 ft., the ore carrying an average, thus far, of 6 oz. gold per ton. This same orebody has been opened on the 750-ft. level, where there is also a separate shoot 450 ft. long and 25 ft. wide; for the distance of 100 ft. the ore from the latter averaged over 20 oz. gold per ton. An orebody was recently opened by driving a cross-cut from the 1000-ft. station, the average of the ore for two weeks being $30 per ton, the gold in this is associated with bismuth and antimony as sulphides. The principal tonnage from the Clermont is being taken from the 600, 750, 900, 1000-ft., and intermediate levels. The Clermont ores now mined average $50 per ton. An important ore-shoot has been cut on the 600-ft. level of the Mohawk, a similar shoot on the 450, and still another on the 350-ft. level. Some ore of good grade has been found recently on the 250-ft. level, above the old Hayes-Monette stopes. The most important of the newer Mohawk developments, however, is the opening of the shoot of ore on the 600-ft. level. New orebodies have been found on the Mohawk and Clermont, within the last two months, on practically all the levels, as well as a new ore-shoot on the fourth level of the Red Top. No new orebodies have appeared in the Combination workings, though the grade of ore there is said to be improving. The Mohawk ores run about 2 oz. gold.

The Florence Goldfield mine and mill are operated under the management of Willis Laurence. The main working shaft, single-compartment, 500 ft. deep, is being enlarged and re-timbered from the lowest station upward, to make room for two hoisting compartments. When the work is finished the 1½-ton skip now in use will be supplanted by four others of ample capacity for hoisting a large tonnage of ore. The double-drum electric hoist, Hendrie & Bolthoff make, now installed, will probably meet the requirements when the larger production is undertaken. The Rand air-compressor, electric and belt driven, has capacity for driving 25 air-drills. About half that number are now in use. Sullivan drills are used for sinking and driving and the work in the stopes is done with Waugh and Shaw drills. The first orebody is about 100 ft. below the surface and the first working level is at the depth of 150 ft. The second level is at 250, the third at 350, and the fourth at 500 ft. There are, however, intermediate levels from which ore is taken through chutes to the main levels. The equipment of the shaft for four hoisting skips will include a 100-ton ore-loading pocket at each of the main stations. The old workings, most of which were done by lessees, show there was a continuous orebody 1200 to 1500 ft. in length. It runs at right angles to the contact of dacite and andesite, and averages 8 ft. wide. There is, though, little regularity in these orebodies. Another vein, known as Engineers', is mostly in dacite, 60 ft. east of the main body, and about 75 ft. long, as it seems cut off by a fault-plane at each end. Much high-grade ore has been taken from it. The dacite-andesite contact, through which the main veins cut at right angles, strike east and stand nearly vertically. The north section of the mine is in dacite and the south, including Little Florence and Rogers shafts, is in dacite. Rich ore is exposed on all the levels; some of the highest grade that has been mined in the district came from the Florence. That which is now being mined and milled has an average value of $25 per ton. In the mine-work all stopes are stulled, the square sets being put in only where there is an orebody of great width, or where it is close under heavy buildings on the surface. A force of 60 men is engaged underground, and 50 on the surface. The mill of the Florence Goldfield M. Co. is treating 175 tons every 24 hours, by amalgamation, concentration, and cyanidation. The crushing is performed by 40 stamps, arranged in two sections of 20, set face to face, the mortar discharge from both sections being into a central launder between the two. Part of the stamps are 950-lb. weight, the others 1050. Their drop is 5 to 6 in., 100 per minute. Half the mortars are of the Hendy type, gauged for 9-in. shoes and dies; the other half are of another type. These are to be standardized. The battery screens are 16-mesh, in which No. 19 wire is used. The pulp from the batteries passes over amalgamating plates, each divided into four sections, resulting in the recovery of 40 to 50% of the gold content of the ore. It is then pumped to three hydraulic classifiers, the spigot discharge from which is concentrated by ten Card tables; the overflow product passes to ten Callow tanks. The concentrate product of the Card tables carries only about 5% silica, the bulk of it consisting of clean sulphide carrying 5 to 7 oz. gold, 2 oz. silver, and 2% copper per ton. The table tailing passes to a hydraulic cone, the spigot product of which is fed into two tube-mills by which it is pulverized to not less than 80-mesh; the tube-mill product is joined by the overflow slime from the hydraulic cone, the two being raised by centrifugal pumps to three hydraulic classifiers. The discharge from the latter is re-concentrated on Card tables, the overflow going to Callow tanks. The settling from these tanks is concentrated over vanners. The Callow overflow and the vanner tailing make up the material that passes to the cyanide plant. It is first received in three collectors, each 36 ft. diam. and 20 ft. deep. It is then passed from the collectors through a mixer to four agitating tanks, 17 by 17 ft., where cyanide solution is first introduced, 1 lb. KCy to one ton of slime being used. After agitating six hours the slime is drawn into Butters filters, the gold solution from the latter being drawn to the precipitating boxes of zinc shavings. The mill work is in the competent hands of W. H. Barton, who was formerly at the Desert mill at Millers, Nevada. Mr. Barton states that by the three processes employed in the mill the total extraction is equal to 95%. In the work of concentration the highest product is from the vanners.

MEXICO.

Oil War.—Shipping Facilities at Tuxpan.—San Pedro Analco — Cinco Minas.—San Rafael y Anexas.

The oil war continues in Mexico, with the Pearson-Aguila interests still forcing the pace. These people claim that the war so far has cost them much less than their competitor, the Waters Pierce Oil Co., and that at the present cut prices they are securing a profit from some grades of oil from their Minatitlán refinery. Sir Weetman Pearson, head of the English firm of S. Pearson & Son, Ltd., who was expected in Mexico at an early date to personally investigate the present oil situation, has changed his plans and will visit Buenos Aires before coming here. It is reported that an agreement for a division of the Mexican territory was recently drawn up by the competing concerns, but that the settlement was abandoned as a result of a demand by the Pearson-Aguila interests for a division of crude-oil contracts, and the refusal of the Waters Pierce company to comply. The Mexican Petroleum Co., at present the most important producer of oil in Mexico, is delivering crude oil and distillate from the Ebano wells and refinery in the State of San Luis Potosí to the Waters Pierce refinery at Tampico, and will be soon in a position to increase deliveries of 'crude' as a result of the opening of the Huasteca fields in the State of Vera Cruz. In the Potrero del Llano, not a great distance from Tampico, the Pearson-Aguila interests have brought in a well that is said to be capable of producing 500 barrels per day, and a 200-barrel well was recently brought in by

the same people at Tanguijo, a new field south of the Tamiahua lagoon, in Vera Cruz. In the San Cristóbal field in Vera Cruz, in which the Pearsons have been operating for some time, oil has been struck in a new well. Deliveries of oil from the Furbero fields of the Oil Fields of Mexico Co. to the Minatitlán refinery will be commenced as soon as the pipe-line to the Gulf port of Tuxpán is extended under water to a point outside the bar, a distance of two miles. Great buoys will be placed at the end of the pipe-line, and tank steamers will be loaded there. In addition to supplying the Mexican markets the Pearsons are exporting refined oil to England. The recent return of a steamer-load of Minatitlán oil from England has been made a feature of the oil war by the Waters Pierce interests, but the Pearsons explain that the oil was some of the first produced at Minatitlán, that it was not properly refined, that their representatives in England made no effort to dispose of it, and that it was returned for re-refining. The steamer that brought the oil to Mexico took back a shipment of the highest grade Minatitlán. A well brought in some time ago by the Mexican Fuel Co., a Waters Pierce concern, in the Topila district of Vera Cruz, is producing steadily.

Some of the money received by José Landero y Cos and associates from the Camp Bird interests for their Santa Gertrúdis stock will be used to equip the San Pedro Analco mines in Jalisco with a cyanide plant, continue development,

Cinco Minas, Hostotipaquillo, Jalisco, Mexico.

and complete the hydro-electric plant on the Santiago river. Mr. Landero y Cos was president of the old Santa Gertrúdis Co., and has been heavily interested in the San Pedro Analco Co. for several years. The San Pedro Analco has just added, by denouncement, 79 pertenencias to its holdings, and the new ground has been given the name of Santa Gertrúdis. John M. Nicol, a mining engineer formerly of San Francisco, has taken a contract to sink a deep winze for the Marcus Daly interests at the Cinco Minas in the Hostotipaquillo district of Jalisco. The winze was started last year, and will be carried to a depth of 1000 ft. The new development work in the Cinco Minas continues to give gratifying results. The Daly interests are organizing a company to carry on operations. Ore assaying from 15 to 22 kg. silver and from 100 to 152 gm. gold per metric ton is being shipped from the Casados mines of the Consolidated Mining Co. in the Hostotipaquillo district. Returns from shipments more than cover development expenses. No stoping is being done, and a big tonnage of high-grade milling ore is being placed in sight. The Virginia & Mexico Mine & Smelter Corporation, which built the first modern reduction plant in the Hostotipaquillo district last July, is now producing from ₱8000 to ₱10,000 per week. Difficulties at the plant are being overcome, and it is expected to double the output within a few weeks.

During the last six months of 1909 the San Rafael y Anexas Co. of the Pachuca district of Hidalgo produced 44,348 kg. of silver and 204 kg. of gold, the value being ₱1,397,187. In that period dividends to the amount of ₱410,000 were paid. The expense of treatment in the company's cyanide plant was ₱3.84 per ton. Orders are being placed for equipment for the 300-ton cyanide plant that the Camp Bird interests will build at the Santa Gertrúdis mines in Pachuca.

NEW YORK.

Amalgamated Co. Reports Holdings.—Copper Producers Assn.—February Figures.—Nevada Con. Direc ors Elected.—United Verde Stock Sold.—Anaconda Appraising Mines.

The great interest shown in the statement of the Amalgamated Copper Co. made last week, has been the cause of no little comment. No corporation founded on mining as a basis has in this country been so widely known. The exposé of the formation of Amalgamated copper, the uncovering of the various cellars, sub-cellars, and secret passages, to say nothing of ground floors, was the first big gun in the campaign of muck-raking that is still in progress. It is not remarkable, therefore, that those who have followed this market leader should be interested in learning what stands back of the hundreds of thousands of shares that have been bought and sold. The application made to the listing committee of the New York Stock Exchange when released showed that the company does not entirely own any of the properties in which it is interested. Its holdings are given as follows: 620,000 shares of Anaconda copper, par $25, out of a total issued capital of 1,200,000 shares; 149,915 shares of Boston & Montana, par $25, total shares issued 150,000; 197,220 shares of Butte & Boston, par $10, total shares issued 200,000; 115,299 shares of Parrot Silver & Copper, par $10, total shares issued 229,850; 9995 shares of Trenton Mining & Development, par $100, total shares issued 10,000; 30,459 shares of Washoe copper, par $100, total shares issued 30,464; 6395 shares of Big Blackfoot Milling Co., par $100, total shares issued 6400; 149,993 shares of Diamond Coal & Coke, par $10, total shares issued 150,000; 1107 shares of Mountain Trading Co., par $100, total shares issued 1110; 100,000 shares of Greene Cananea, par $20, total shares issued 2,500,000; 50,000 shares of Butte Coalition, par $15, total shares issued 1,000,000. The output of the producing mines Anaconda, Washoe, Parrot, Butte & Boston, Trenton & Boston, and Montana is stated to have been during 1909, 292,000,000 lb. copper, 9,837,268 oz. silver, and 59,074 oz. gold. It is further stated that the company has never considered it necessary to block out large ore reserves, but that there is as much ore blocked out now as at any time. The Big Blackfoot Milling Co. is stated to own over 1,000,000 acres of timber lands, and two large saw mills. The profits derived from this company have not been distributed in dividends, but have been invested for some years in additional property. The Big Blackfoot Milling Co. is to be reorganized into the Big Blackfoot Lumber Co., and all of the stock will be owned by the Amalgamated. The property of the Diamond Coal & Coke Co. consists of about 13,000 acres of coal land in Uintah county, Wyoming. The laws of Wyoming do not allow a mining company to operate company stores. The Mountain Trading Co., was, therefore, organized to take over the commissary department of the coal company. This is the first statement ever made by the Amalgamated, giving a list of the securities owned by it, and the statements made by the various subsidiary companies are also the first ever made covering their production. Butte & Boston reports a profit for the six months ending June 30, 1909, of $282,384; Boston & Montana for the same period, a profit of

$1,134,911; Washoe Copper, a profit of $667,791; the Parrot, which has for a long time been reputed to be making just about a new dollar for an old one, shows a deficit for the period covered, of $42,860. The income account of the Amalgamated covering a period from May 1, 1909, to January 1, 1910, shows dividends received from subsidiary companies, $2,949,354; other items, interest on loans, etc., $405,762, total income $3,355,116, less administration expenses, $70,682; net income for the eight months, $3,284,434. There is outstanding $153,887,900 of the capital stock of the Amalgamated, and the net earnings as given are equal to a little more than 2.13% on the issued capital, or a little better than 3% per annum. Amalgamated copper sells at about $82 per share, and pays 50c. per share quarterly. Goldfield Consolidated sells for $8.50 per share and pays 50c. per share quarterly. This is not the only comparison that is being drawn against some of the coppers. Utah copper is selling at $50 per share, and paying $3 per year, while Kerr Lake, the Lewisohn property at Cobalt, is expected to declare the same rate, 75c. per share quarterly, at its next meeting, and Kerr Lake sells for between $8 and $9.

There was not a little disappointment manifested when the figures of the Copper Producers' Association appeared March 10. February being a short month, and Western mines having a great deal of severe winter weather to contend against, it was expected that production would show a material curtailment and that the copper surplus would as a result of further inroads be reduced to a comparatively negligible quantity. It was something of a surprise, therefore, when the report showed an increase of nearly 9,000,000 lb. Exports are figured by the association at 37,369,518 as against custom house figures of 55,538,000 lb. This discrepancy is due to the fact that some 23,000,000 lb. of copper billed for export were included in last month's figures of the Producers' Association, but did not clear through the ports until in February. The production in February was 112,712,493 lb., being a decrease of but 3,834,794 lb. from January figures, and being really an increase in per diem production. The copper surplus on March 1 was 107,187,992 lb., as against 98,463,309 February 1, the net increase being 8,724,683. Domestic deliveries for February were about what was to be expected, totaling 66,618,322 lb. The statistical position of copper is not as strong as it was thirty days ago, and the necessity for further curtailment is plain. To paraphrase the late John Sherman, "the way to curtail is to curtail."

The long drawn out struggle between the Utah Copper crowd and the Nevada Consolidated stockholders headed by James Phillips, Jr., has resulted in the exchange of 859,361 shares of Nevada Con. This is not sufficient on its face to carry the absolute control of Nevada Consolidated, which has an issued capital of 2,000,000 shares, par $5. At the meeting held March 10. C. M. McNeill, D. C. Jackling, and S. Guggenheim were elected to the board of directors.

It has not generally been supposed than any stockholder of the United Verde Copper Co., outside of Senator W. A. Clark, held as much as 500 shares of United Verde. There was a good deal of interest, therefore, in the sale of 500 shares of the stock this week at auction in New York at $70 per share. Otto Sussmann is making an examination of the Granby for the American Metal Co., Ltd., which is the American representative of Henry R. Merton & Co., Ltd., of London. The examination of the Granby has renewed the talk of the consolidation of the important producers of the boundary camp. A. B. W. Hodges, who has for many years been general manager of the Granby, has recently resigned his position to become general manager of J. B. Haggin's Cerro de Pasco mines in Peru. Mr. Hodges' successor has not yet been chosen. Mr. Hodges has also for several years been consulting engineer for the Shattuck-Arizona, one of the recently developed producers at Bisbee, Arizona. The Esperanza Mining Co., Ltd., of El Oro, Mexico, has increased its quarterly dividend, according to London advices by cable March 10, from 1s. to 1s. 6d. J. F. Kemp, of Columbia University, Herman Keller, and P. L. Foster, of New York, are engaged with B. B. Thayer, of the Anaconda Copper Co. in making the appraisals of the various Amalgamated mines at Butte.

TORONTO, CANADA.

Cobalt Shipments and Improvements. — Railway to Porcupine Promised.—Mackenzie & Mann Invest on Bear River.

Shipments of ore from Cobalt for February amounted to 2276 tons, as compared with 2115 for February 1909. The list for February last is headed by La Rose with 566 tons, followed by Nipissing 400 tons, Kerr Lake 388, and Crown Reserve 291. The Cobalt Power Co. has for some time been delivering power in small quantities from Ragged Chutes on the Montreal river and the supply has lately been increased, among the companies receiving power from this source being the Coniagas, the Cobalt Central, and the Temiskaming. The Nipissing and La Rose are also preparing to handle it. The Mines Power Co. is developing an electric current from the Matabetchouan Falls, and will have two stations at Cobalt for generating compressed air, and in addition wires have been erected for electricity. Contracts have been signed with a number of companies. It is altogether reasonable to anticipate that the arrival of cheap power will largely increase shipments. One effect is already evident in a slight upward movement in the stock market, affecting mainly the cheaper issues. At the Temiskaming high-grade ore has been found at the bottom of the shaft at 425-ft. depth. The quartz-calcite vein in which it occurs runs through the mine, but previously had not carried anything better than a little milling ore. The pay-streak varies from 2 to 12 in. At the Nipissing the Meyer vein at 185 ft. shows a width of 6 to 8 in. of high-grade ore, and on the 75-ft. level the ore runs in places 9000 oz. per ton. Vein No. 100, worked from the Fourth of July shaft, varies in width from 2 to 4 in., with rich silver content. Raises are being driven to connect the first and second levels of the Fourth of July vein, where stoping will shortly be commenced. On vein No. 64, remarkable for its great width, 18 to 36 in., high-grade ore has been found at 300 ft. The two lower levels are being connected with raises preparatory to stoping, and development in this and other workings has considerably increased the ore reserves. The Gifford has struck a 3-in. calcite vein heavily mineralized with copper, galena, and iron. The Rochester in driving and cross-cutting at the 45 and 75-ft. levels has encountered a number of promising veins. At the 45-ft. level from the new shaft known as No. 3 the vein which showed at the surface over 5000 oz. silver per ton, was again cut. It is 5 in. wide and apparently as rich as on the surface. Two narrow high-grade veins have been found at the Crown Reserve in a cross-cut at the 100-ft. level. At the La Rose in a raise from the 135-ft. level from the shaft on the hill on No. 3 vein a new ore-shoot has been found, and driven on about 50 ft. It averages 4 or 5 in. of high-grade ore.

The Ontario Government has announced that railway facilities are to be given to the Porcupine mining district. A branch line of the Government road, the Temiskaming & Northern Ontario, will be run through Whitney and Tisdale townships. The first shipment of ore has been made from the Porcupine camp. It comprised six tons of high-grade ore and was from Timmins Bros., who are operating the Hollinger property. The Ontario Government just now is being subjected to severe criticism in the Legislature for its vacillating and unbusinesslike way of dealing with the Gillies Limit properties. The whole business is being overhauled by a committee of the Legislature. One particularly rank deal entailing a heavy loss to the province has been disclosed whereby the lot now owned by the Wyandoh company was sold to J. A. Young and M. J. O'Brien for $10,000, and a few weeks afterward changed hands at $330,000. Of course valuable discoveries had been made in the meantime, but the question naturally asked is why the Department of Mines, with the resources at its disposal did not make them before putting the property on the market.

D. D. Mann, of Mackenzie & Mann, vice-president of the Canadian Northern Railway, has made an important investment in British Columbia mining lands. In association with a number of American and Canadian capitalists he has secured control of 4368 acres along the Bear river in the northern part of the province, north of Prince Rupert and the main line of the Grand Trunk Pacific.

General Mining News.

ARIZONA.

GRAHAM COUNTY.

The New England & Clifton, formerly known as the Copper King, has a shaft down 8875 ft. on the old Copper King vein. During the year the New England has installed large compressors and machine-drills, and an aerial tramway about two miles in length. A concentrator and smelter are promised during the present year.——The Polaris mine is now being operated by a development company, which has a bond on the stock of the old Polaris company. The company owns about 40 claims, and has done considerable development which has exposed some important bodies of copper ore of good grade. This property is in the vicinity of the New England holdings.——The Weaver group has recently been taken hold of by the Shannon Copper Co., which is now pushing development. As the surface showing is good, this property should be heard from as a producer.

MOHAVE COUNTY.

(Special Correspondence).—The U. S. S. R. & M. Co. has nearly completed road building and equipment work, and mine development is under way. At Stockton Hill three large hoists have been installed on the Banner, Bryan, and Infallible properties, and sinking started. The Banner, which is generally regarded as the strongest vein in the Cerbat range, is already partly developed by an adit 1900 ft. long, every foot in ore, making the longest continuous ore-shoot in Mohave county, and one of the longest known. The ore is a lead-zinc, containing gold and silver.——Farther north, and in the same range, the Champion and Twins mines have been equipped with new hoists. The shafts are being enlarged and retimbered preparatory to additional sinking. In its Little Jimmy and Big Bethel mines, which adjoin the Golconda zinc mine, the company is drifting and cross-cutting. The shaft of the Big Bethel is in a porphyry dike, whose average width is 75 ft., and as the zinc of the district occurs in such dikes, a cross-cut to prospect it has been started from the 200-ft. level.——Ore has been found at 45 ft. in the new shaft on the C. O. D. property.——At Chloride draining of the Tennessee mine is progressing slowly. Though the surface waters, which were believed to be the main cause of the delay have been flumed, two pumps of 120-gal. capacity have been unable to lower the water in the shaft. A bad cave, at a depth of 115 ft., caused more trouble and resulted in shifting of timbers for 70 ft. above. A 150-gal. Dow pump is now being installed.——The Dandy mine, in the Weaver district, about 25 miles northwest from Chloride, has been sold by William Hall to J. P. Hutchinson, of Chicago. Mr. Hutchinson, who is associated with Charles Schwab in the San Toy silver mines of Chihuahua, Mexico, sampled the property several months ago. The main vein, which is developed by a shaft 220 ft. deep, and by about 1000 ft. of drifts, contains an average of 3½ ft. of ore, assaying $20 per ton. A cross-cut from the 200-ft. level has exposed a second vein with 5 ft. of ore averaging $11. All the ore is free-milling and a high saving has been made in the small mill on the property by a straight amalgamation process.——The discovery made at the Tom Reed, at Oatman, last week at a depth of 250 ft. in shaft No. 2, is showing better with development. Driving has been started toward the main shaft 1500 ft. away, and the entire face of 5 ft. shows high-grade milling ore. The new mill has been accepted.——The Boundary Cone mine is installing a hoist and compressor. On an adjoining prospect Bob Rohe and Henry Lovin have exposed a vein from which samples taken across 4 ft. assay $8 per ton in free gold.——Work has been started on an extension of the Kingman power line to the Hercules mine, in the Silver Creek district, where a stamp-mill and cyanide plant are to be built.——H. N. Tracy, president of the power company, was in the district a few days ago and stated that another unit would be added to the plant at Kingman immediately.

Kingman, March 12.

PIMA COUNTY.

The Pioneer Smelting Co. will have its new customs smelter completed by next July. J. A. Highlands, the general manager, is in Denver, where the machinery is being built. Mr. Highlands recently contracted in New York for a traction engine and several freight cars for use in hauling the machinery to the smelter. The site for the smelter has been graded and everything now awaits the material.

YAVAPAI COUNTY.

The Consolidated Arizona Smelting Co. has announced that its plant will be open for receipt of ore not later than April 1.——The Great Republic has discovered a body of sulphide ore containing copper and gold in the cross-cut from the 300-ft. station of the main shaft. The ore, as far as exposed, shows an average thickness of 20 ft. Driving the cross-cut has been discontinued, but the shaft is being sunk to the 500-ft. level.——Active development is to be resumed at once on the properties of the Commercial Mining Co., in Copper Basin. A. J. Pickrell, who has charge, is sinking a new double-compartment shaft 4 by 8 ft. in the clear, perpendicular and well timbered. It will be sunk on a large quartz porphyry dike which cuts through the basin. The shaft will be sunk a short distance from the site of the Copper Basin reduction plant built twenty years ago and later dismantled. The sinking of the deep shaft has been under consideration since large bodies of ore were uncovered and partly exploited by Brown & Murphy. John Edwards and his associates three years ago furnished a large tonnage to the Humboldt smelter at a handsome profit. The Commercial Mining Co. is allied with the Phelps, Dodge & Co. interests.——Another company which will begin work at once is the Saratoga Gold Mining Co. Good mechanical equipment is on the ground with accommodations for many men. Under the direction of O. Place, a shaft about 250 ft. in depth was sunk. The showing was attractive and the property was rated as one of the best in that zone. The belt on which the six claims are situated is one of the oldest known in that district, and in the original exploration was known as the Moody & Place properties. The fissure was traced to the Crowned King mine, which, on being opened gave to the Bradshaw region its fame as a mining centre.

YUMA COUNTY.

Discoveries continue to be made in the Thumb Butte mining district. W. R. English a few days ago found a vein of gold-bearing quartz one and one-half miles from the original discovery, a sample assaying $3360.——E. O. Grady and his wife have located a claim three miles from the Thumb Butte shaft which shows free gold and which will, undoubtedly, assay well.——A dozen outfits are working in the hills around Thumb Butte, all finding promising rock.——J. P. Moffat, in charge of the work at Thumb Butte, reports the work at the mine in good shape.

CALIFORNIA.

AMADOR COUNTY.

The South Eureka is being examined and sampled with a view to purchase. Levels at 1500 and 2700 ft. are known to be in ore.

KERN COUNTY.

A gusher was brought in March 4 on the Sec. 30, 31, and 32 tract of the Mays Oil Co. The well shot a stream of oil over 400 ft. from the rig. Before anything could be done thousands of barrels of oil had flowed down the canyon. It is estimated that the well was producing at the rate of 30,000 bbl. per day, when it bridged and ceased flowing. The drill was down to a depth of 2790 ft. when the gusher was brought in. This is the biggest producing well in this section. A sump with 8000-bbl. capacity was filled in less than an hour and the oil flowed for a distance of over two miles. It is of high gravity and tested 22.5. So great was the force that a large hole was soon worn through the pipe leading to the sump hole.——A protective association for the benefit of oil men in this field has been organized with W. L. Leland as chairman and E. M. Sheridan as secretary. The association members "agree to submit controversies in reference to claims to title rights or possessions, where

there are adverse claimants to Government land, to an executive committee of five men, to be appointed by this association, and to abide by the result of the majority decision of an arbitration committee of three men, to be appointed by not less than four of said executive committee."

NEVADA COUNTY.

Williams Brothers and Clyde Cole, operating the Red Ledge mine near Washington, have discovered quartz assaying $8 to $10 per ton while ground sluicing.——The Canada Hill mine is being unwatered and is now open to a depth of 1000 feet.

SHASTA COUNTY.

The Michigan copper mines, adjoining the famous Bully Hill, has been bought by New York capitalists, who have incorporated the Bully Cave Co., and placed E. J. McLaggan in charge as superintendent. The Michigan group was located by the pioneer, H. H. McClure. Next to the Bully Hill, it is the best copper mine in this district.——W. A. Winberg has taken a bond on the Conners group of mines on Salt creek. A force of a half dozen men has been put to work.——The Uncle Sam mine has installed a compressor. About 20 men are employed.——James Sallee has purchased for $5000 the Lyon group of claims adjoining the National property on Rich gulch and the old Murray claim on Flat creek. For the latter the price was $1500.

SIERRA COUNTY.

(Special Correspondence).—The Sierra Butte has resumed operations with a small force of men. The Hayes Brothers, of San Jose, are owners.——Los Angeles people are arranging for the immediate resumption of activities at the Mountain mine. The property embraces 688 acres and is equipped with a 40-stamp mill. Next to the Sierra Butte it is the largest gold property, from point of tonnage developed, in the county, the owners placing the reserve at from 130,000 to 160,000 tons, above the main tunnel, that will average $4 per ton. The owners state that working costs will not exceed $1.75 per ton, and that $40,000 will be expended in developments. President L. H. Carver will take personal charge of the work.——The Snowden Hill has suspended operations until the equipment can be increased. The presence of deep snows has greatly interfered with operations during the winter.——The cross-cut from the Sixteen-to-One vein to the Tightner vein in the Twenty-One mine has opened a shoot of rich ore. It ranges from 10 to 24 in. wide. The strike was made at a point 240 ft. below the Tightner lower adit. F. M. Phelps is manager.

Downieville, March 11.

SISKIYOU COUNTY.

Martin Schuler, superintendent for the Scott Bar Hydraulic Mining Co., is getting the mine and ditch into shape to start mining.——Nesbitt & Crawford are working a crew of men in their shaft at Scott Bar and have found good ore. ——Hicks Brothers are driving an adit on a very promising pocket stringer near Scott Bar.——The McAdams creek dredge is now running and is operating smoothly. About 20 men are employed.

COLORADO.

BOULDER COUNTY.

R. D. George, State Geologist, returned March 2 from Washington, D. C., where he has been in conference with the Director of the United States Geological Survey and arranged for co-operation between the State and Federal Geological Surveys. As a result Federal surveyors will be in southern Colorado fields surveying the topography of that part of the State early next summer. The State Survey will send several parties to work in and around Leadville and in Garfield county and to test the clays of the State.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Bell adit on Seaton mountain has been driven for 200 ft. Scattered ore is showing and the bore will be advanced 1300 ft. additional. ——Moonan & Co., leasing on the first level of the Shafter, are stoping on a 12-in. streak of gold-silver ore that mills $90 per ton. On the third level Warren & Co. are driving east, following an 18-in. streak of $22 ore. This drift will be extended to cut under the workings of the first named operators.——Work is to be resumed in a few days on the Bertha mine, situated on Seaton mine. The property has passed over to the Dollar Savings Mining & Milling Co. Large funds are said to have been provided.

Idaho Springs, March 8.

EL PASO COUNTY.

J. S. Smith, of the Colorado Tram Co., is constructing an aerial tram for the Standard plant of the United States R. & R. Co. at Colorado City. He recently finished building a similar tram for the Little Brothers company at Canon City.

GILPIN COUNTY.

(Special Correspondence).—The Buell mill, at Black Hawk, is being overhauled and repaired preparatory to bringing the machinery into commission. The plant has been purchased by the U. P. R. M. & M. Co. The water from the Buell mine is to be lifted to the 700-ft. level.——Large

Gregory Buell Mine, Gilpin County.

development is under way at the Iroquois property. During the last 18 months the shaft has been sunk for 200 ft., while 1000 ft. of driving has been performed.——Shipments have been started from the Senator mine, the last returns recorded being 1.15 oz. gold and 12.68 oz. silver per ton, with 7.20% in lead.——Lyng & Co., leasing on the Indiana, are sending out regular shipments of smelting and concentrating ore, the first class milling as high as $300 per ton, while the second class brings $40 per ton.——The Gilpin-Eureka Mining Co. has placed an order for three 50-kw. transformers which are to be used in the mill, while a 75-hp. compressor is to be purchased for the mine.

Central City, March 8.

GUNNISON COUNTY.

The Spar-Copper mines at White Pine, consisting of 56 patented acres, have been sold to the United Mining & Holding Co., of Boston, Massachusetts. The consideration is said to have been $60,000. The mines were purchased and patented by Charles L. Tutt, now deceased. At the time of his death, Mr. Tutt in developing the Spar-Copper group had cut, in the deeper Parole tunnel, six long rich ore-shoots with 600 ft. of backs. The property has a creditable past production. Large ore reserves are now opened, and a fine equipment is at hand.

LAKE COUNTY.

The Belgian shaft will be sunk an additional depth of 250 ft. to uncover the large sulphide orebodies that have already been developed in the adjacent claims, such as the Tucson, Louisville, Adelaide, and Humboldt. The Belgian has never been troubled with water. The properties are well equipped with substantial buildings and good machinery for hoisting. The shaft is down 620 ft. Nearly all of the new work will be carried on through the Yak tunnel. ——A new plant of machinery has been erected on the Red Hook, one of the Iron mine properties.——Lead carbonate to the amount of 25 tons per day is being shipped from the Corona.——Andrew Hill has completed the erection of a plant of machinery on the Printer Boy mine. This was necessary on account of the heavy demands on the old plant since a vein of gold-bearing ore was found. The

Printer Boy is one of the historic mines of the district.——The Lovejoy, also on Printer Boy hill, is producing. This property is working under the management of H. J. Hersey. A gold-bearing ore is mined. The product is hauled to the Moyer switch at Oro.——The electric compressor at the Saguach tunnel in the Sugar Loaf district has been installed and is now ready for operation. It is a 75-hp. machine, situated at a station 250 ft. from the portal of the tunnel and connected with the lines of the Central Colorado Power Co. The tunnel itself is now in the hill 600 ft. The bore is 6½ by 7 ft. in the clear. This enterprise has been promoted and financed by the National Mining & Milling Company.

OURAY COUNTY.

Organization of the Wanahak Mining Co. was completed on February 26 with John T. Robert, president; E. C. L. Bartow, vice-president; Samuel McCurdy, treasurer; G. H. Barnhart, secretary and general manager; and B. H. Du Praw, mine superintendent. The capitalization is $400,000. The company owns and operates the Bright Diamond property north of Ouray. Since December 16 men have been at work in the development of the mine. Ore has been blocked to the extent of about 30,000 tons. A compressor plant and tramway will be installed as soon as weather conditions will warrant, and a concentrating plant with the initial capacity of 100 tons per day is being arranged for. All the ore from the mine will be treated locally at the pyritic smelter north of town. A new contact vein of ore, five feet thick, has been opened above the upper contact which has been worked for years. Five raises have been made into this upper ore zone, covering an area of more than 100 ft. square, and proving its continuity at least to that extent. The concentrating ore will average from $9 to $16 in value.——Ore is reported from the Atlas mine in the Sneffels district. Fred Carroll, the manager, says that in one of the drifts a shoot of the characteristic free gold Atlas ore has been uncovered. The shoot is of considerable extent. Work in the east drift along the vein to connect with the workings of the San Pedro is rapidly progressing with something like 1800 ft. intervening between the breast of the tunnel and the objective point. The ore along the vein is proving continuous and of excellent value.

SUMMIT COUNTY.

The American Zinc Extraction Co. is continuing its shipments of about 30 tons of ore per day from the Little Sallie Barber property, in the Breckenridge district, to Leadville. The mine was taken over by this company more than a year ago and has been operated successfully and continuously since. It is one of the best zinc producers in that portion of the State. Many improvements have been made on the mine itself under the new management.——Gibson hill is rapidly coming to the front. Wright & Lipp, at the Standard, have run into a 7-ft. streak of hard carbonate ore, containing gold to the amount of over $20, with some silver and lead.——Work at the Wellington mine and mill is going on with the usual regularity, and the cars on the track are being filled as fast as the teams can get the ore from the mill. Lack of trains from and to Denver temporarily disarranged shipments early this month.——The power house at the O'Reilley mine is completed and ready for the machinery.

TELLER COUNTY.

More men are employed at present at Cripple Creek than for many years. This is due to the large number of lessees at work and also to the mining of low-grade ore made possible by the United States R. & R. Co.'s recent cut in treatment charges. March is starting out with a heavy daily tonnage and the month is expected to close with a big gold output.——Fackerell and associates, operating on the Buena Vista property, on Bull hill, have made their initial shipment. The lessees are working principally between the sixth and eighth levels, where ore assaying from $30 to $40 per ton is opened to a width of three feet. The Buena Vista is owned by the Isabella company and Fackerell and associates are sub-leasing from H. C. Harris. The Western Investment Co., leasing on the Empire State of the Isabella company, is making a good monthly tonnage with the ore averaging $22 per ton.——Seaver & Henry, operating on the Peggy mine, on Gold hill, above the town of Anaconda, shipped a car of ore. The lessees are breaking ore assaying $20 per ton from a vein 2½ to 3 ft. wide.

MONTANA.

FERGUS COUNTY.

The Lentz Mining & Development Co. in the Twin Bridges district was recently sold at sheriff's sale to satisfy a judgment of $600. Messrs. Harvey and Oppenheimer, of Pittsburg, have appeared on the scene, and as two of the big stockholders in the company they propose to redeem the property and resume development. John A. Drake and others of New York own a controlling interest in the North Moccasin gold mine which was sold recently to satisfy a judgment given in favor of the Bank of Fergus county as trustee for the bondholders for $121,643. The North Moccasin is regarded as one of the best gold mines in the Kendall district and adjoins the Barnes-King.

SILVER BOW COUNTY.

The property of the British-Butte Mining Co., three miles west of the city, will not be mortgaged in order to raise funds to pay off its indebtedness. At a special meeting called for the purpose of ordering a mortgage on the property, it was announced that the directors had completed arrangements to settle the debts. Operations at the property stopped last fall, and it is said that the debt is in the vicinity of $260,000. The work of the company has been carried on with considerable difficulty in regard to reaching the gold-bearing ground. From 5 to 7 ft. of clay has to be removed by the dredge and then about 2 ft. of gold-bearing ground is reached, resting on false bedrock. The dredge cannot work beyond the rock. An engineer is now at work making a thorough examination of the property and among the officers there is a belief that operations will be resumed.

NEVADA.

LANDER COUNTY.

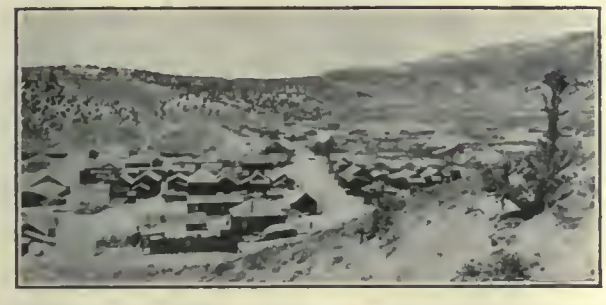
(Special Correspondence).—A French syndicate, represented locally by M. Labardee, of Golconda, has bonded several silver-lead and gold properties near Galena and is negotiating for sites for power and reduction plants. The Hider ranch, comprising 15 acres and several valuable springs, has been secured and negotiations are under way for the Wilson ranch of 160 acres. The latter will be used to deposit the tailing from the mill. The plans call for the erection of a cyanide mill and smelter. The ores will be sent from the various properties to the reduction plants by means of a tunnel 4500 ft. long. Work on this has already commenced.——The drift from the adit on the Mayer-Reber lease is said to have opened 25 ft. of ore running $8 per ton in gold. The strike was made at a depth of 100 ft. The lease is on Nevada-Omaha estate.——The Dalton-Haworth lease has opened 6 ft. of milling ore at a depth of 30 ft.——The Bannock Mining & Leasing Co. has cut a narrow seam of white quartz carrying iron pyrite. It is expected that ore lies near by.——The Moscow lease, on the Golden Bee, is making good progress and reports fair ore.——Owing to the storms and high water in the Reese river, transportation has been tied up and several properties have been forced to suspend until the shipment of ore can be resumed.

Battle Mountain, March 5.

WHITE PINE COUNTY.

(Special Correspondence).—The output of copper from the Steptoe Valley M. & S. Co. for February was 5,000,000 lb. of blister copper, which was about 1,000,000 lb. short of the December record, because of severe winter weather. As the mines of the Nevada Consolidated are now producing an average of nearly 8000 tons of ore per day, it is expected that the present month will be a record maker. The ore is all produced by steam shovels at Copper Flat.——The Ely Centennial is installing a drilling and lighting plant. The equipment was purchased last week in Salt Lake, and is now on the road to the mine. The property is being rapidly developed, and makes a splendid showing of high-grade copper ore.——A flow of water was struck in the Clipper shaft of the Ely Central last week which came in with

such force as to threaten the submerging of the pump. Lee Glockner, the manager, immediately wired to Salt Lake for another and a larger pump, which is now on the road. It will be installed and in operation in a few days when work will be resumed in the shaft. The same company has been having a considerable amount of trouble with its Eureka shaft, which is in soft wet ground, and hard to hold. The superintendent has resigned and it is expected that Jack Gallagher, formerly of the Homestake mine in



East Ely, Nevada.

the Black Hills, will shortly arrive to accept the position. ——E. W. Ralph, manager of the Boston Ely, is this week installing a machine-drill which will be used in extending the cross-cut from the 1125-ft. level of the Emma shaft. The cross-cut has been in ore for the past 50 ft. and is expected to reach the limestone on the contact about the latter part of the month.

Ely, March 12.

TEXAS.

BREWSTER COUNTY.

(Special Correspondence).—The Black Kettle group of copper claims, near Sierra Blanca, are now owned by a syndicate of Baltimore men. Considerable development work has been done upon the property and preparations are being made to resume operations on a large scale.—— It is reported that the Hazel mine, owned by H. J. Clifford, will soon be reopened. This property, which is situated near Van Horn, was closed down in 1895 owing to the decline in the price of silver and has been idle ever since. It has a record as a producer of rich silver ore, the shipments that Mr. Clifford made to the smelter assaying as high as 5000 and 6000 oz. per ton. During the short time that the mine was operated it netted $251,000 above all expenses. The workings are only 575 ft. deep.——The station of Marathon, situated on the Southern Pacific, 25 miles east of Alpine, will soon become the shipping point for the Del Carmen Mining Co. which is developing a rich zinc mine on the Mexican side of the Rio Grande, just opposite Boquillas. An enormous quantity of ore is already on the dump awaiting the completion of an aerial tram across the river. The company has gone to heavy expense constructing a wagon-road from the river to Marathon, about 90 miles. It is stated that the ore-wagons will be pulled by traction engines. The United States Government recently established a sub-port at Boquillas in order to handle the importations of zinc ore from this mine.

Alpine, March 10.

UTAH.

JUAB COUNTY.

The Holden tunnel, which is being driven from the town of Eureka, a distance of 3000 ft., to the Centennial Eureka mine, will be completed within a couple of weeks. This tunnel will tap the main working shaft at a depth of 500 ft., and a station will be cut and a pump installed for raising the water from the 2200-ft. level. The tunnel was started last September, and has been opened rapidly. The pump was ordered in Switzerland and shipped six weeks ago. It will have a capacity of 1000 gal. per minute, and will reach the mine to be installed immediately upon the completion of the tunnel. With the draining of the lower levels of the mine a larger tonnage of ore will be extracted, and heavier shipments made to the United States smelter at Bingham Junction. The copper furnaces of this smelting plant have never been completed, as the management claims the company would not be justified in doing so until larger contracts for smelting copper can be closed.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The Granby Consolidated has acquired the Summit group in Phoenix district, of about 20 claims, nearly 1000 acres. The property is known to contain large deposits of low-grade copper-gold ore similar to that now being mined on the Granby property. A large contract for diamond-drill exploration has been awarded to Boyles Brothers.——The coal property of the Columbia Coal & Coke Co., near Princeton, is to be opened immediately. George L. Fraser, formerly with the International Coal & Coke Co., at Coleman, is in charge.——The new Rand compressor and other heavy machinery recently purchased by the Hedley Gold Mining Co. has arrived and is being installed.——The Le Roi No. 2, Ltd., shipped in January 2440 tons of ore worth $42,358. This included 58 tons of concentrate, worth $1515.——Zinc-lead miners near Nelson note with pleasure that the Dominion Government will expend about $50,000 in experimental work on zinc smelting. ——The Van Roi Mining Co. went behind about $20,000 during the past year, due to a 1300-ft. adit being driven to open the deposits at depth and make a straight working level. Ore has been cut in this work and will shortly be developed. With steady operation it is expected the property can be made to pay nearly $175,000 per annum. The higher tariff on zinc concentrate imposed by the United States Government upset the plans of the company.—— Shipments from the Yankee Girl mine are temporarily suspended owing to the bad condition of the roads. Snowslides have caused minor damage to the plants of the Ymir, Queen, and Wilcox mines in Ymir and Sheep Creek districts.—— The Crows Nest Pass Coal Co. shipped an average of 4100 tons per day during January, constituting a record. The Hillcrest coal mines are making delivery of 25,000 tons to the Great Northern at Michel.——A five-drill air-compressor and an electric lighting plant is being installed at the Perreault mine in the Portland Canal district.——J. P. Morgan is stated to have bought an interest in the Swede group, Morseby island, Queen Charlotte Islands. The average ore assays 3½ to 4% copper. The property adjoins the Sullivan group which changed hands some days ago.——The Marble Bay mines, Texada island, look promising. On the 1000-ft. level a 250-ft. shoot of bornite is being worked that is 20 ft. wide and carries approximately 9% copper, $7 gold, and 25 oz. silver.——It is understood that the Dominion Government does not intend to renew or continue the existing bounty on iron and steel.

Rossland, March 12.

MEXICO.

SONORA.

(Special Correspondence).—The Southern Pacific railroad company has completed its branch line from Corral to its coal land concession on the west side of the Yaqui river. The first regular train ran March 6. The company obtained the concession of about 6500 acres some ten years ago and did considerable prospecting for two years. The work opened 38 veins of anthracite coal having an approximate dip of 30°. These vary from 1 to 12 ft. in thickness. Operations were suspended at the property and work on the branch line started. The road is 110 miles long following the course of the Yaqui river, the grading has been difficult as much of the road-bed had to be shot out of the solid rock with a number of tunnels along the line. The work has opened a large portion of the Yaqui valley and a number of prospects are now in position to become paying mines. The lead-silver ores have been the best developed to date, but there are a number of copper prospects with a few whose chief value is in the gold content. At one place near La Dura a dike has been opened that is 200 ft. wide and assays from $4 to $6 per ton gold, with portions that run as high as $15 to $20 per ton. But very little work has been done on this property on account of the high cost of freighting.

La Dura, March 5.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

FRED T. WILLIAMS is at Butte.

J. T. DURYEA was in San Francisco.

J. W. INGERSOL is at Tonopah, Nevada.

R. H. BURROWS is at Chihuahua, Mexico.

ALGERNON DEL MAR is at New York City.

ROBERT R. HEDLEY is at Victoria, British Columbia.

E. L. BECK is at Carrville, Trinity county, California.

R. A. F. PENROSE, JR., has gone to Europe for a month.

J. P. IDDINGS has been spending the winter in the Philippines.

C. E. KEYES, JR., of Oakland, has gone to Kennett, California.

F. M. FIELD is in New York on business pertaining to a mill in Idaho.

JACOB W. YOUNG has left Cobalt, Canada, and is now at Philadelphia.

LEO D. DOUGAN, of Plumas, South Dakota, is now at Wickes, Montana.

GEORGE B. JAQUES, JR., has gone to New York from Round Mountain, Nevada.

LYON SMITH is at Cortez, Nevada, for the Cortez Metals Recovery Company.

JULIUS BURGGROF is now with the Real del Monte company at Pachuca, Mexico.

T. H. OXNAM, JR., is with the Bonanza Gold M. & M. Co., Victorville, California.

F. WALLACE WHITE, of Chicago, Illinois, has moved to Springfield, Massachusetts.

E. D. NORTH has left Tonopah for Los Angeles, where his address is 1033 Ingraham street.

CHARLES F. SHELBY has gone to La Fundicon, Peru, for the Cerro de Pasco Mining Company.

H. A. BALL has been appointed resident manager for the Imperial Gold Mining Co., of Canada.

J. P. MONTAGUE is superintendent of the new mill of the Tonopah Extension M. Co., at Tonopah.

S. H. BRADY has taken the management of the properties of the West End M. Co., Tonopah, Nevada.

E. G. WOODFORD, who is now living at Tacoma, Washington, is at the Palace hotel, San Francisco, this week.

R. E. SCHULTZ, of Pierce City, Idaho, has removed to New York City, where his address is No. 2 Rector street.

HENRY FRANCIS LEFÉVRE was in New Orleans from Costa Rica recently, but sailed immediately for Central America on mining business.

T. H. JENKS has returned from Gunnison county, Colorado, and is now temporarily at 403 Commerce Building, Kansas City, Missouri.

D. M. MUNRO has resigned as manager for the El Favor Mining Co., Hostotipaquillo, Mexico, and is returning to the United States and Canada.

GODFREY D. DOVETON and E. G. SPILSBURY, of the metallurgical staff of Spurr & Cox, Inc., are working on the cyanide mill of the Virginia & Mexico Co., at Hostotipaquillo, Mexico.

THE CORDILLERAN SECTION of the Geological Society of America will meet at the University of California March 25 and 26.

CHARLES F. AARON, general manager for the New York Leather Belting Co., died at his home in Plainfield, New Jersey, March 4.

ON FRIDAY, March 4, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 150 of $75,000. This makes the amount of dividends paid since January 1, 1910, $180,000, and the total to date $11,466,000.

EDITORIAL.

FIRES in the National Forests were less destructive last year than in 1908, despite the number being 410 greater. Almost 80 per cent of the fires were extinguished before five acres had been damaged. In reducing the annual fire-loss the Forest Service is of great and much appreciated benefit.

APPARENTLY the interests of the United States in Mexico are in competent hands. Mr. Henry Lane Wilson, the new ambassador, who was presented to President Diaz on March 6, made a speech that was admirable. With many expressions of goodwill, he carefully avoided reference to matters which have been the objects of recent diplomatic negotiation. Mr. Wilson knows how to express himself graciously, without being either blunt or oracular.

THE MINING MAGAZINE for March contains the usual departments, with interesting editorials. Among contributed articles of special note are: 'Steel Making in China', by Thomas T. Read; 'Dredging at Neviansk', by Chester Wells Purington; 'Sintering of Copper Ores', by Walter G. Perkins; 'The Great Mines of the Rand', by T. A. Rickard. Mr. Purington's account of work on the Siberian placers will be read with particular interest on the Pacific Coast where dredging is such a large and profitable industry.

DOUGLAS is fairly seething. As one local writer puts it "the smelting pot of the world, literally boiled" when it was learned that the Los Angeles Chamber of Commerce planned to spend no more than a beggarly hour and a quarter there, while touring Arizona. This is no case for interference by an innocent bystander, but we do venture to assert that Douglas can entertain any body of distinguished guests much longer than seventy-five minutes, and still keep them interested.

REDUCTION of the iron in ferruginous copper slags in the electric furnace is the subject of an interesting communication by Mr. Lewis T. Wright to the Transactions of the American Institute of Mining Engineers. He points out that the metallic iron so produced carries with it practically all the copper, gold, and silver, and more than 50 per cent of the sulphur of the original slag. The current used varied from 70 to 80 amperes, and the time of fusion was approximately an hour and a quarter. The copper content of the slags was reduced in one case from 0.55 to 0.1 per cent, and in others from an average of about 0.3 to 0.05. The concentration was approximately 25 per cent.

OURAY, according to *L'Illustration*, was a prospector of French deseent who in 1906 diseovered rich gold veins in southwestern Colorado and so gave name to the beautiful little mountain plaee which is cited as an example of the promptness with which cities are built by 'get rich quick' American methods of 'booming'. The Indian chief Ouray, who really gave name to the mountain, county, and town, has been so long dead that he probably will not mind this attempt to supplant him, but to deny existenee to the city itself prior to 1906 would require rewriting mueh eventful history. We fear that our Paris contemporary itself has fallen into the hands of a 'get rieh quiek' spaee writer.

CONSERVATIVE methods mark the operation of the Tennessee Copper Company. During 1909 it made no effort to augment its production. This was 14,058,954 pounds, a trifle below the point reached the previous year. The cost was 10.57 cents per pound, in which are included depreciation, interest, and retirement of bonds to the extent of $50,000. The depreeiation account now stands at $187,000, in addition to which there is a general reserve fund of $75,000, and $7276 retained as liability insurance. The price received for copper during 1909 averaged a little less than 13 cents, and a dividend disbursement of 5 per eent on the capital stock of $5,000,000 has been made.

BRAZIL has been making extensive investigations of its iron resources. These are said to be so great that the State of Minas Geraes alone can supply the world with iron and steel for centuries. Discounting the hyperbole, and admitting the impossibility of being certain of the quality throughout such enormous masses of ore as there exist, or of foreseeing the world's demands through such periods of time, the fact remains that Brazil is blessed with reserves that bid fair ultimately to shift the centre of iron-production across the equator. Gen. F. M. de Sousa Aguiar has recently arrived in this country as special commissioner from Brazil to study the steel industry and to arrange for the exportation of iron ores to North America.

PERMANENT injunction was granted last year against the Arizona Copper Company, Limited, and its neighbors, restraining them from discharging tailing into a stream from which it would overflow upon adjacent agricultural lands. The ease was notable because of its accentuation of the rights of the individual against the privileges of a corporation on which a considerable community depended for a livelihood. The outcome of the injunetion has been the presentation of suffieient evidence to show that the objeetionable tailing can be impounded, so that the judge has ordered a suspension of the injunction pending decision on an appeal which has been taken to the Supreme Court of the United States. A special officer of the court is appointed to inspect the works for impounding and restraining tailing, and a bond for $20,000 has been executed as guarantee against damages which may be sustained by Mr. William A. Gillespie, in whose favor the earlier decree was entered.

TAXES on mining property in Mexico are due in Mareh, July, and November of each year. It may be of interest to those who, for any cause, become delinquent to know that immediate forfeiture of title does not ensue. The tax may be paid the following month with the addition of a penalty of 50 per eent, and if delinquent into the second month, the property may be redeemed by paying double the amount of the original tax. If, however, the tax is not paid within 60 days the perteneneias become forfeit and hence subject to re-location.

LESSENED activity in mining eireles, so far as the initiation of new business goes, has been a feature of the last six weeks, both in the West and the East. The demand for lead and zinc has been good, but the copper market has not rallied as was expected two months ago. The addition to the surplus stocks of that metal, as shown by the Copper Producers' Association, had a chilling effeet, and discouraged preparations for the opening of mines that are awaiting a price of 15 cents. A remarkable circumstance is the steady growth of the steel business, without a corresponding increase in the demand for copper. The indications are, however, that the world is probably consuming the output on the present basis of production. The March and April output of the copper refineries will apparently be reduced somewhat, but this cannot have a beneficial influence upon the mining centres, except as it insures the properties now active against neeessity for curtailment. It may be assumed that the statistics of the steel trade and railroad returns constitute a reliable barometer. The outlook is for good industrial weather, which must improve the position of all metal-producers. The gross earnings of the leading railroads of the country for February were 13 per cent in excess of those for the corresponding month of 1909, which period had shown a similar improvement over February 1908. This gain is the more interesting when it is remembered that February of this year was eharaeterized by unusual obstructions to traffie by storms in the West and Northwest, and that the cotton movement showed no improvement. The growth of traffic was due to the expansion of trade in general, whieh inevitably leads to an increased demand for metallic products.

Proposed Seismological Studies.

Earthquake studies under the direetion of the Smithsonian Institution are now proposed. Mr. Bois Penrose has introduced an amendment to the sundry eivil bill, appropriating $20,000 for beginning the work. The matter has been referred to the Committee on Geological Survey in the Senate and to the Library Committee in the House. The suggestion is excellent and it would seem that even in these days of 'economy' so small a sum might well be spared to so important an object. The United States has lagged behind in seismologic studies despite their great scientific and practical interest. It has been abundantly shown that no part of the country is free from earth-tremors, and destructive shocks have occurred at Boston, Charleston, and in the Mississippi Valley, as well as on the Pacific Coast. Careful

studies of the duration and intensity of the minor as well as major shocks are needed. Periodic measurements of the relative displacements of fixed points on the surface would probably enable the growing stresses of the earth to be measured as accurately as is the movement of a glacier. It is even probable that something may be done in forecasting earthquakes, and it is certain that field-studies will permit the mapping of the territories likely to be most damaged by shocks. The Japanese have done much by intelligent study and they probably stand at the head as students of seismology. They are closely followed, if not equalled by the Italians, while the Germans at Strassburg are attacking these problems with the method which has done so much to secure their position in science and industry. Following the earthquake at Valparaiso, Chile established one of the most complete stations yet built and secured as Director, Count Montessus De Ballore, one of the foremost European investigators. The interest of the United States is at least equal to that of any country, and it can not well be expected that others will solve our local problems. A small sum regularly spent on the work would be adequate, and the Smithsonian Institution is admirably adapted to administer such a trust economically.

Two Institute Meetings.

During the first week of March two great societies representing mining technology in North America held their meetings. The American Institute of Mining Engineers assembled on March 1 at Pittsburg, and the Canadian Mining Institute met at Toronto on March 2. Both meetings were characterized by an unusually large number of important papers. As was eminently fitting, deference was paid at Pittsburg to the coal and iron industries that make the greatness of the metropolis of western Pennsylvania. Messrs. F. Z. Schillenberg and Edward McGrew discussed the 'Systematic Exploitation of the Pittsburg Coal Seam', which means so much for the future prosperity of the district. The wasteful methods of earlier days have been giving way to better practice, reducing the loss in gob and unrecovered pillars. Mr. William H. Blauvelt described 'A Commercial Fuel-Briquetting Plant', and naturally the testing plant of the Technologic Branch of the United States Geological Survey received attention, both by description in a paper presented by Mr. Joseph A. Holmes, and by a visit to the laboratory where demonstrations were made in the presence of the members. The School of Mines at the Pittsburg University, and the Technologic Schools of the Carnegie Institution also claimed suitable notice. Aside from these papers the meeting was notable for three contributions that mark forward steps in the development of technical operations. One of these was the announcement of Mr. E. Gybbon Spilsbury of a new system of air-agitation of slime in the cyanide treatment of gold and silver ores. The distinguishing feature of the innovation consists in the introduction of the air into the pulp so distributed that its passage through the slime in bubbles of appreciable size is prevented. The object is, so to speak, to saturate the pulp with air, instead of merely to agitate it with bubbles. The wastefulness of air in agitation increases with great rapidity as the diameter of the bubbles become greater. The ratio between the volume and the surface of the globule when the diameter is unity is exactly as 1 to 6, whereas with a diameter of one thirty-second it is nearly 1 to 153. Mr. Spilsbury describes a diaphragm which he calls a silica-sponge, impervious to solids, but permitting the free passage of air under pressure as low as two pounds per square inch. The pulp is aerated by treatment in shallow tanks, the bottoms fitted with the silica-sponge, an air-pressure of not more than six pounds per square inch being used. The time of treatment by this method is claimed to be less than six hours, while the consumption of cyanide is reduced.

Other noteworthy contributions to technologic advance were the papers by Mr. Robert H. Richards, past president of the Institute, on the 'Development of Hindered Settling Apparatus', and by Mr. Harrison E. Ashley on 'The Chemical Control of Slimes'. The investigation of slime is one of the greatest problems confronting the metallurgist today. It is growing constantly more important as the exhaustion of high-grade ores compels resort to leaner deposits, in the treatment of which, whether by cyanidation in the case of gold and silver ores, or by concentration in the case of copper and other metals, the loss in slime constitutes an enormous proportion of the whole. It is doubtful if any of the great concentrating works today save 75 per cent of the total metallic content of the ore, and many are vainly striving to keep the public from discovering how far below 60 per cent their extraction falls. Whatever contributes to an understanding of the physical conditions existing in slime, and to reliable methods for overcoming the resistance offered to the release by flotation or by settling of the metallic minerals, will add distinctly to the resources of the world.

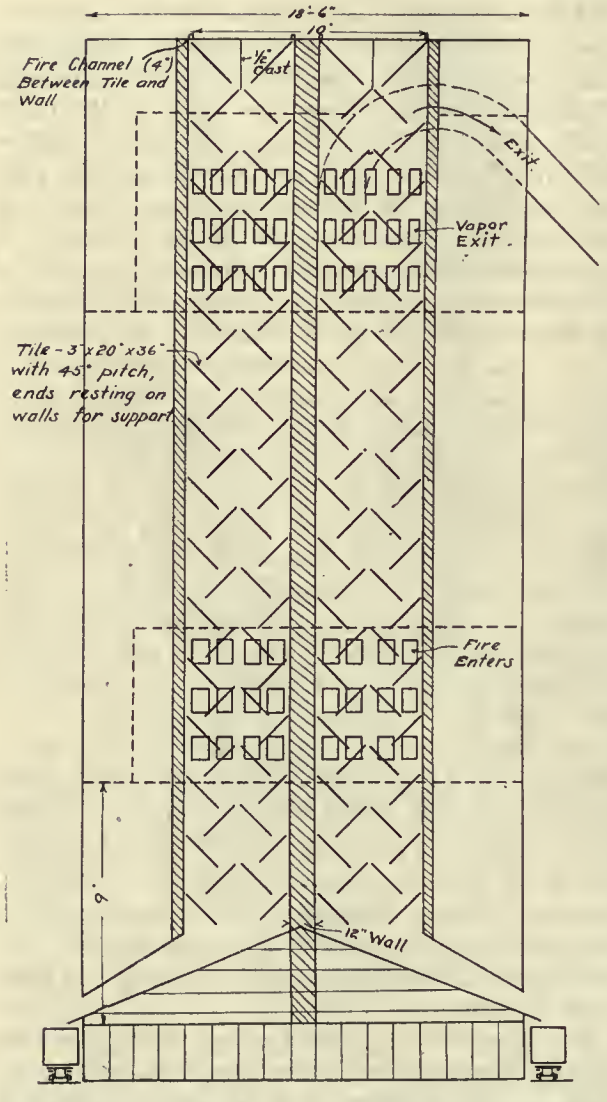
The address of welcome was made by Mr. John A. Brashear, to which a felicitous reply was made by the president, Mr. D. W. Brunton. Dr. R. W. Raymond performed the sad duty of giving obituary notices of two of the leading spirits in American technical circles, Charles B. Dudley and William Metcalf, both distinguished for their splendid contributions to knowledge of the character and treatment of steels.

We have given extended notice of the Canadian meeting elsewhere in this issue, so that further comment on the excellent work of the Canadian engineers need not here be made. At Toronto emphasis was laid upon electro-metallurgy, which is appropriate in view of the abundant water-power close to the centres of population in the Dominion. The report of the Council showed the Institute to be in excellent condition as regards membership and finances. The election of Mr. F. D. Adams to the presidency, following Mr. Willett G. Miller, is a high compliment to the geologists, and indicates a pleasant appreciation of the close relations of mining to scientific investigations. America is fortunate in having two such societies as the American and Canadian mining institutes.

Guadalupe Quicksilver Works.

Written for the MINING AND SCIENTIFIC PRESS
By COURTENAY DE KALB.

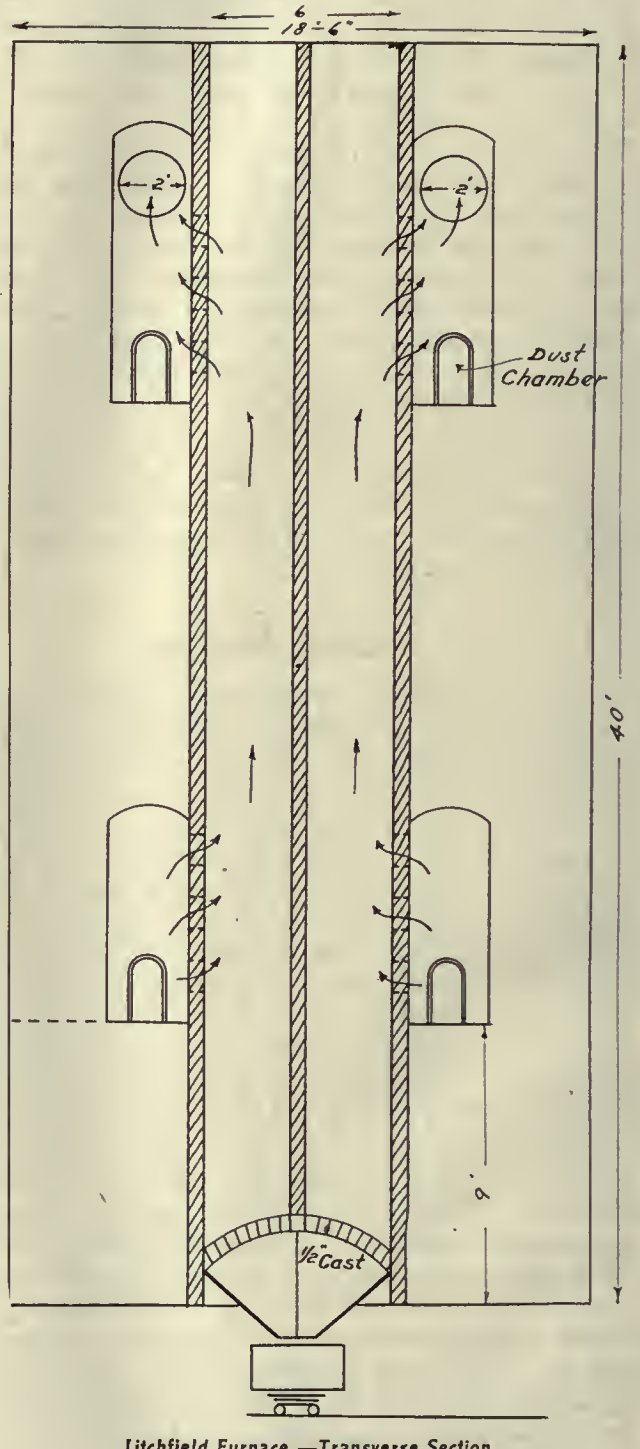
Cinnabar was first mined in Santa Clara county, California, in 1824, by Antonio Sunol and Luis Chaboya. The property was originally called the Chaboya, but was later christened the New Almaden, appropriately perpetuating in America the fame of the great quicksilver mine of Spain. A short distance from the New Almaden property is the Guadalupe, which also has had a record of large production from the early days of mining in the State. Extensive operations were begun here in 1855 by the Santa Clara Mining Association of Baltimore, and



Litchfield Furnace, Great Western Quicksilver Mine.—Longitudinal Section.

continued until 1875, when the property was sold to the Guadalupe Mining Company of California, which conducted the work with falling fortunes until 1886. It then remained idle until 1890, when the Century Mining Co. was organized by H. C. Davey, later taking the name of the New Guadalupe Mining Co., and a new period of productivity was inaugurated that has lasted to the present. In its palmy days the mine yielded as much as 1900 flasks of quicksilver per month. This was when high-grade ore was available. The output is now 200 flasks, of 75 lb. each, per month, the recovery averaging 2% of the total ore treated.

The original main shaft was sunk in the valley close to the channel of Capitancillos creek, and the workings reached a depth of about 1100 ft. Much difficulty was experienced with water in the mine, and the decreasing tenor of the ore rendered econ-



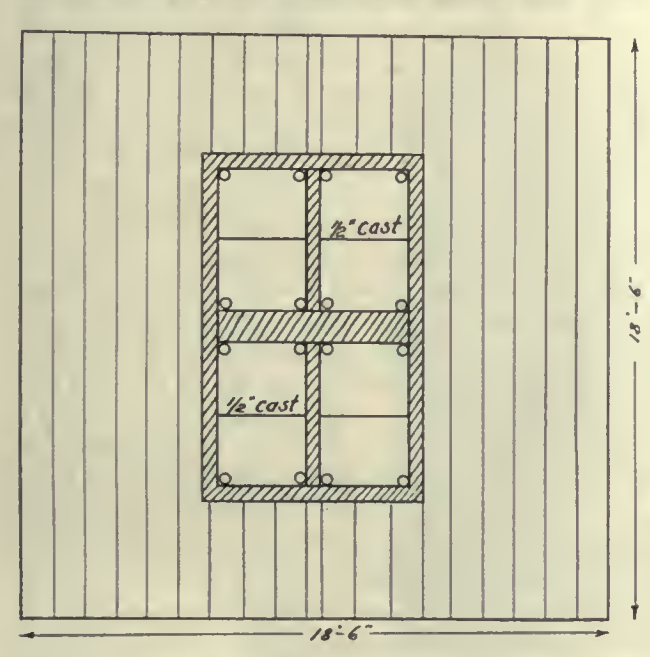
Litchfield Furnace.—Transverse Section.

omical mining impossible. The hills on both sides of the creek were also extensively prospected and considerable ore found. The deposit now worked is at a depth of about 700 ft. under the hills on the north side of the creek, and is reached by an adit over 2000 ft. long. The cinnabar occurs in serpentine in proximity to intrusive masses of rhyolite. The exact content of the ore is unknown, but the extraction is quite complete. Of the total recovery as much as 63% is obtained as metal direct from the condensers, the remainder being extracted from the

soot. This result is probably due in large part to the fact that oil is now used for fuel, and the combustion being quite perfect the amount of soot produced is small. The soot carries mercury with it, and the reduction of the quantity of soot necessarily lessens the percentage of the metal which fails to condense and drain from the condensers.

The ore on coming to the works is crushed in a Hendy rock-breaker, 8 by 12 in., the feeder consisting of a short trommel, thus avoiding the re-crushing of material already fine enough for the furnaces. An elevator takes the product to a screen with 1½-in. holes, dividing it into coarse and fine grades which are distilled in separate furnaces. The average size of the coarse ore treated is 3 inches.

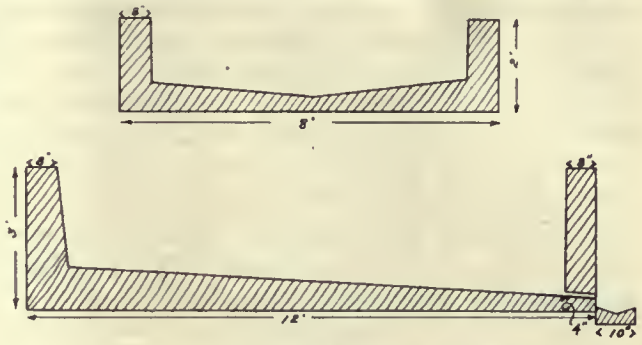
The distillation takes place in modified Litchfield furnaces. The accompanying drawing shows a typical Litchfield furnace, such as is used at the Great



Plan of Litchfield Furnace.

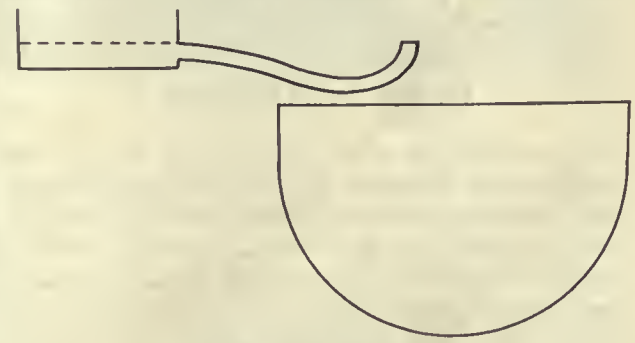
Western Quicksilver Co.'s mines in Lake county, California. It consists of tall distillation chambers with inclined tiles placed so as to cause the ore to slide downward in a zig-zag from the feed-hopper at the top to the base where it is drawn off into cars. The double distillation chambers are paralleled with chambers in which fire is maintained, the heated gases passing through ports from these. The Litchfield furnace used at the Guadalupe mine differs in important details. It has eight distillation-chambers or 'channels', 40 ft. high, and 3 by 6 ft. each, in horizontal section, the block being 30 by 18 ft. in plan. The upper part of each channel contains a constriction called a 'throat' which the ore completely fills as it passes through. Above the throat is a dryer, consisting of a prolongation upward of the channel, fitted with additional inclined tiles. This device is an improvement patented by H. C. Davey. An auxiliary fire is used to effect the drying in this upper shelf-furnace. The condensers at the Guadalupe works are brick chambers, two in number, placed tandem. They are of red brick, and are 12 by 40 ft. in plan and 20 ft. high. From these the fume passes through a series of brick flues, 2 by 3 ft., expanding into smaller condensing chambers at frequent intervals. The total travel of the fume from the retort-furnaces to the stack is 3000 lineal feet, and draft is induced by a 6-ft. fan placed at the entrance to the stack. The fan is driven by a 2-hp. motor.

There are two blocks of furnaces, the fine-ore furnace having a capacity of 30 tons per diem, while the coarse-ore block treats 12 tons. Calcined ore is drawn off every hour. The oil burned amounts to



Soot Table.

1 bbl. to each 10 tons of ore distilled. The soot was formerly distilled in iron retorts, but is now treated on concrete 'soot-tables' 12 ft. long by 8 ft. wide, made in the form of a broad shallow V-shaped trough, inclined from the head toward the discharge end. The soot is placed on the sloping floor of this table, where it is hoed with ordinary garden hoes at frequent intervals. The metal collects into globules of sufficient size to run out of the soot, which is left undisturbed a few hours after each hoeing. In this way the extraction is so perfect that but little quicksilver remains, and the soot is then returned to the ore fed into the top of the distilling furnaces. Cement-lined brick channels lead from all the condensers and from the soot-tables to cast-iron quick-



Mercury Siphon and Kettle.

silver wells of 3-ton capacity, which are kept locked. Above the wells are boxes which receive the mercury before it passes into this final receptacle. These boxes are partly filled with water, and a 'goose-neck' pipe leads from the bottom of each, overhanging the well. Thus the quicksilver is freed from dirt and grease, and automatically discharges as it accumulates.

Labor in the works consists of three men to each shift of eight hours. Sixty men in all are employed, above and below ground. Extensive improvements are under way, including the installation of a 125-hp. Pelton wheel, to take water under a head of 734 ft. This will drive air-compressors for drilling in the mine, in addition to operating the surface works. At the present time 75 hp. is consumed, this being developed by a water-wheel.

The Northern Cascades.

Written for the MINING AND SCIENTIFIC PRESS
By HORACE F. EVANS.

Although some progress was made in the international boundary region in the seventies and eighties, it was not until recent years that mining on a permanent and successful basis began, and the industry has of late been stimulated by the introduction of capital, following the further extension of the continental railway system. It was not until 1901 that George Otis Smith and staff made a geological reconnaissance across the Cascade range near the forty-ninth parallel, and in 1902, the data for the Osoyoos quadrangle were obtained. This work was in charge of R. A. Goode, geographer. The topographic mapping was done under the direction of L. C. Fletcher, and the triangulation was in charge of C. F. Urquhart and J. G. Hefty.

This quadrangle is a 30-minute strip from Lat.

Part of the Osoyoos Quadrangle.

48.30 to 49.30′ and from Long. 119 to 119.30. The elevations are from 913 to 6065 ft. above sea-level. The chief features of the quadrangle are the Osoyoos basin, Osoyoos lake, Okanogan valley, and the junction of the Okanogan and Similkameen rivers.

The Osoyoos basin possesses a climate that differs greatly from the country surrounding it. The climate is semi-arid. Sagebrush and cactus comprise much of the characteristic vegetation. Trees are comparatively scarce, and bunch-grass is not so plentiful as in the adjacent mountains. The annual precipitation in the immediate vicinity of Osoyoos lake is small, and the summers are dry and hot. The thermometer in summer has been known to register 114° in the shade and sometimes a little more. The temperature in winter is milder in the Osoyoos basin than in the surrounding country, and even in exceptionally cold winters the temperature in the vicinity of Osoyoos lake is always higher than elsewhere in the valley. Snow remains only a few days on the ground, and the winter season is short.

A noteworthy exposure of the rocks of the Similkameen and Okanogan valleys within the Osoyoos basin occurs about a mile and a half northwest of the town of Oroville, Washington, and a good view of the rock-sections may be obtained from the Great Northern trestle-bridge across the Similkameen. The Carboniferous rocks, comprising slates, some of them schistose, with sandstone, limestone, and with conglomerates and interbedded volcanics, are seen to much advantage from this point and at the sides and in the bed of the Similkameen river. The Carboniferous rocks with the granites are overlain by sandstone, the structure and lithology of which suggest a later age. Near the trestle already mentioned a gray sandstone occurs, holding plant remains and pieces of coal, suggesting Eocene age, but details are wanting as to the sandstone and some other overlying rocks, including some coarse conglomerates that may be a remnant of the basal Cretaceous, though the official geologists have provisionally assigned these conglomerates to the Tertiary. Overlying most of the later sediments near Oroville are andesites, some of which are hornblendic in character. The andesites are extrusive as well as intrusive, and in the case of three exposures near Osoyoos lake it has been determined that the relation of the sedimentary and volcanic rocks is one of unconformity.

In the hills lying between the Similkameen river and Osoyoos lake in the Okanogan valley, the sections show a black silicious slate lying in a trough of contortion, on beds of gneissic mica slate, where the latter occupies the higher ground in the centre of the hills. On the western shores of Osoyoos lake thick beds of coarse conglomerate occur, having a dip of 70° in a direction E. 25° S. About 1200 ft. to the west these beds have been strongly folded and lie at nearly as high an inclination to the west. Near the old crossing at the international boundary a thin band of hard feldspathic porphyry is found to be intruded in the beds, and close to this, in 1861, H. Bauerman, then geologist to the British section of the International Boundary Commission, while making examinations in the neighborhood, found a bed of sandstone close to a small sheet of water, carrying green and blue carbonates of copper. The carbonates covered a considerable portion of the sandstone surface. No lode could be found, but it was ascertained that the carbonates were produced by the decomposition of quantities of chalcopyrite in grains scattered through not only the sandstone but in other rocks in the neighborhood.

In later years Noel B. Kelsey, a prospector who had acquired some experience in California and Nevada, began the exploration of the country thus pioneered by Mr. Bauerman. Kelsey's investigations resulted in interesting Michigan capitalists who organized the Detroit-Oroville Exploration Co. some months ago. This corporation has begun the systematic development of the copper area immediately west of Osoyoos lake and south of the international boundary, and proceedings were commenced some time ago to secure a patent to these holdings which include much of the ground examined by Mr. Bauerman nearly 50 years ago.

Not far from Oroville, and close to the junction of the Okanogan and Similkameen rivers, green and black slaty rocks are continuously exposed. They are contorted similarly to those mentioned as occur-

ing on the hills, but no gneissic rocks seem to come to the surface. Much of the granite of the Similkameen country is hard and finely crystallized. It contains mica and hornblende, with white and red feldspar. Syenite occupies a considerable area, and both are penetrated by numerous feldspar porphyry dikes.

The property of the Detroit-Oroville Exploration Co. comprises a part of Sec. 5, T. 40, R. 27 E., and consists of 15 claims, on all of which copper ores occur. During the summer of 1907 I made an examination of the conditions under which copper ores exist on the property of the Exploration company.

The Osoyoos basin seems to have been a sedimentary area from Paleozoic time, and the Paleozoic column was evidently capped by Permian rocks. I found the intermixture of copper carbonates, oxides, and sulphides to be a marked characteristic all over the area and also in adjacent properties. The shape and manner of occurrence of the ores are somewhat irregular. Within the mineralized zones is always a clue to the ore, though this may at times be faint. The most important occurrences appear to be in the limestones and sandstones, though details are yet wanting. The area is an old sedimentary one from Paleozoic times, which has been overlain by later sediments and subsequently intruded by andesites. The andesitic covering at one time evidently occupied a much greater extent of territory than at present. The sedimentary beds were uplifted and fractured, and possibly fissured, in late Tertiary age. Porphyritic and quartzose material fills seams, fractures, and other cavities. These are often found containing chalcopyrite of a rich yellow color, with associated carbonates and oxides.

The granite seen across the lake does not appear to have forced tongues into the sedimentary beds on the west side, and from this it is inferred that the granite is not intrusive on that side of the lake. The evidences of contemporaneous deposition in the limestones do not seem to conflict with the theory that the copper ores have been recruited or reinforced by the agencies accompanying the andesitic invasion, for the copper ores evidently possess more than two distinct sources. The later rocks, such as the conglomerates, hold copper-bearing pebbles from the black slates which are known to be of Carboniferous age, while there is nothing that definitely determines the character of the surface-deposits of copper. No data are yet available to determine approximately the extent of the upper portion of the copper-bearing sediments that was removed by denudation, but a large volume of the andesite-capping evidently has been removed by erosion.

In the spring of 1908 the Exploration company, acting on a recommendation in my report, contracted for 600 ft. of boring to determine the relations of the copper-bearing sediments in six different parts of the field. For this purpose a diamond core-drill of the Sullivan 'Beauty' type was brought to the ground and six different holes were put down. The lowest hole was on the flat ground near the shore of the lake, and a depth of 110 ft. was obtained. Three holes were put down vertically, and three at various angles. In every instance copper ores were found to the limit of depth bored. In the arenaceous rock the occurrence was the same at the lowest depth reached as at the surface, namely, fine grains of chalcopyrite disseminated through the rock. The carbonates disappeared at a depth varying from a few feet below the surface to 40 ft., and were rarely seen beyond that distance. The bottom of the zone of oxidation was not reached. In a semi-arid country oxidation may extend to 300 ft. or more.

Sullivan Drill at the Detroit-Oroville Exploration Co.'s Property.

The richest cores were from a limestone, somewhat silicified and altered. In a zone of dark slaty rock the cores showed small quantities of copper glance. In a number of instances calcite veins appear to have determined the precipitation of the copper. The peripheral zone, lying between the sedimentary rocks and the andesite is accentuated by an abundance of quartzose material, though no detailed investigation of the conditions existing in the direct contact between the andesites and the Carboniferous sediments has been made. The areal extent of the copper ores is not limited to the boundaries of the corporation's property. On adjacent properties and even on the east side of the lake, copper ores occur in slaty rocks and in quartzose sediments, but investigations there have been almost exclusively superficial. Some assays of hand samples of copper ores taken from the Exploration company's property have been made, and these have varied from 1.75 to 30.13%, with gold at times from a trace upward. The bore-holes will be deepened also by a diamond core-drill for the purpose of determining the conditions at a greater depth.

Relation Between Mineral and Chemical Industries.—II.

By George T. Holloway.

*My experience with the rare minerals found in the older rocks induces me particularly to refer to the vast field which they furnish for research for those who regard the rare metals from the commercial point of view, for those who wish to improve our present defective methods of both qualitative and quantitative analysis, and for those who are searching for new elements. I would especially draw attention to the 'black tin' concentrate obtained from the tailing and slime run to waste from the 'dressing floors' of the Cornish tin mines. This waste passes down what is known as the Red river from Camborne to the sea at Gwithian, and is collected and re-treated over a length of about eight miles, by 16 independent firms or individuals known as 'streamers', each of whom extracts as much as possible from what passes by his holding. Finally, on Gwithian beach, where the waste passes into the sea, the waves perform the last dressing operation, and, at low tide, little patches of the heavy tin ore which have thus been collected, are scraped up by the last of the tin dressers, to complete the tally. It is an interesting proof of the neeessity for efficient dressing appliances for minerals, to note that the Red river produce amounts to over 800 tons annually of 'black tin'—which, by the way, is red—containing an average of about 50% of metal, notwithstanding that the ore, before the waste is rejected by the mines, has passed through more dressing processes than any other mineral with which I am acquainted.

My excuse for this digression, is that the black tin from the Red river contains not only the tin, but there have become concentrated in it minerals of tungsten (representing, according to my analyses, an annual loss of over 100 tons of wolfram), uranium, vanadium, tantalum, niobium, molybdenum, and other known heavy rare metals as well as strong indications of rare elements, which have somewhat similar properties, but which have not yet been isolated. Those who have had experience with tin and wolfram ores from certain Cornish mines and elsewhere, have encountered difficulties in their analysis due to the presence of unidentifiable metals, and, as the waste from most of the mines passes into the Red river, the natural concentration originally made by nature in the rocks and followed up by the ore dressers at the mine, has been completed by the streamers. The minerals of the rare elements, owing to their greater friability, became more finely ground than the tin during the dressing of the ore and therefore pass into the slime so that the produce from the Red river, consisting, as it does, mainly of slime, forms an ideal material for research, being always available in large quantity, easily procurable, and probably containing in the most accessible form, many of the missing links which, since the discovery of radium, have become of interest and probable value.

*Abstract from Bulletin of the Institution of Mining & Metallurgy.

The fact that radium is a product of the breaking down of uranium and that uranium and all the allied heavy elements, as well as many of the light elements which may also be products of similar degradation of elements, occur, so far as we know, only in deposits which are distinctly of the most deep-seated and ultra-plutonic origin, may perhaps be coupled with the peculiar force or 'emanation' which frequently accompanies sudden volcanic outbursts, and which kills so instantaneously as not to be attributable to any gas or to any cause with which we are acquainted.

The occurrence together of practically all the heavy rare elements and the almost invariable occurrence with them, or at any rate in the same or similar rocks, of many of the rare alkali, alkaline-earth, and allied elements such as lithium, caesium, rubidium, cerium, thorium, didymium, beryllium, zirconium, etc., is of extreme interest. All occur in pegmatites or other of the oldest and particularly the acid rocks, and practically none are found elsewhere except under conditions directly traceable to such an origin. Where uranium abounds the other heavy metals are usually present in comparatively small quantity and the other groups of rare elements are practically non-existent while, under conditions where uranium is absent or only found in comparatively small quantity, the others may be found associated either as components of minerals of complicated constitution or each in its own characteristic mineral form.

It is extremely probable that there is a definite connection between these occurrences and the birth or decomposition of the elements, and that a study of them may elucidate many doubtful points more simply and conclusively than attempts, however well directed, to artificially produce results which Nature has already achieved. The occurrence of fluorides with these rare metals or in the rocks where the same occur, is also of importance. Both fluorspar and cryolite are commonly, although by no means always, associates of them, and it is considered by many that these fluorides, which often occur in fissure veins in granites, diorites, gneisses, etc. of great age, have been produced, in many cases, by the action of metallic fluorides whose decomposition has resulted in the production of metalliferous deposits and of such fluorides as fluorspar and cryolite, and of minerals containing fluorine, such as topaz, tourmaline, etc. The important and growing use of flourspar and cryolite as fluxes in metallurgical operations, has resulted in a great increase in their production during recent years. The color of topaz, zircon, and many others of the more or less precious stones which occur in the old rocks, is probably often attributable to the action of uranium or other radio-active substances and the effect of uranium and radium in coloring these stones and such minerals as fluorspar and quartz, with which uranium minerals occur, is now fairly well known. Certain peculiarities in the color of these two minerals, as found in place, are even taken as an indication of the presence of uranium by the miners. The first reference to this property was made by Richard Pearce, who published a note on the subject in the Journal of the Royal Institution

of Cornwall in 1861, long before radio-activity was dreamed of, and experiments have recently been made by him and the author in this direction with radium itself.

The peculiar action which the heavy rare metals have when added to steel shows how curiously they stand as a class distinct from others. Uranium, tungsten, molybdenum, tantalum, niobium, vanadium, and even titanium, have extraordinary powers in producing special effects when added to steel, even in small quantity. These powers might be considered only as of passing interest from the point of view of the chemist, were they not practically confined to one group of metals and possessed more or less by each member of that group. It is true that valuable properties are imparted by other metals, such as aluminum, manganese, nickel, and chromium, but their effects are less marked and are produced by the addition of a comparatively large quantity of the metal, excepting in the case of aluminum, whose action is, however, of an entirely different nature.

The recent demand for these rare metals has resulted in a large increase in the production of the minerals containing them. They were commonly passed over by the prospector or ignored by the analyst, and the present increased supply is mainly due to increased education, and is much on a par with the production of monazite and other thorium-containing minerals used for incandescent lamp mantles, and now obtainable from alluvial and other deposits in many parts of the world, in addition to its early and only source in Brazil. Over 200 million of such gas mantles are now produced annually. The best concentrated monazite sand averages only about 5% of thoria and other earths actually required by the mantle industry, so that a large field is open for research to utilize the ceria, zirconia, didymia, etc., which are obtained as by-products.

Tantalite, at one time almost unobtainable, is now found in larger quantities than are required, and is even produced as a by-product in washing cryolite, with which it occurs, as might have been expected from a study of the natural associations of the rare elements mentioned above.

Reliable statistics as to the output of minerals of the rare metals are not obtainable, but it may be mentioned that the world's output of tungsten ores was over 5500 tons in 1908, as against about half as much in 1905, although the price obtainable per ton had nearly doubled during 1904-8.

A lengthy list of important close associations of certain of the ordinary commercial minerals might be added with a commentary as to the reasons for such association, but want of space forbids more than a passing reference to them.

The invariable association of selenium and tellurium with sulphur, of cadmium with zinc, and of nickel with cobalt, and the common association of potassium and sodium, of calcium, barium, and strontium, and of the halogens excluding fluorine, is too well known to need comment. They may be explained by the similarity of their properties, but there are many other mineral associations of elements which, like that of the precious metals as compared with lead, are not in any way similar, and a knowledge of them is of great assistance to the mining man and mineralogist in searching for minerals and in his anticipation of what may be expected to follow such indications as are found in prospecting, as well as to the metallurgist and chemist as a guide in searching for valuable or objectionable constituents in such minerals as he has to treat.

One of the most common associations is that of zinc blende with galena, copper and iron pyrite being also usually present. Such an association is objectionable in every way commercially, and although these minerals may be separated mechanically, hydraulically, or magnetically, when the minerals are not so fine-grained or so intimately interlocked that a preliminary crushing will not break them apart, millions of tons of ore of high assay value exist which have not yet been treated at a profit and which are known as 'refractory zinc-lead ores'. When it is remembered that ores containing zinc, lead, silver, and gold to the amount of perhaps ten pounds or more can be obtained for little more than the cost of mining, of almost uniform composition and in unlimited quantity, there is no wonder at the numberless attempts which have been made to solve the problem and which have raised more hopes and emptied more pockets than any other metallurgical problem during the last century.

It is true that pyrite as such, does not constitute a commercial ore of iron, but the oxide left by the roasting of pyrite is regularly smelted for the production of pig iron, and it must not be forgotten that a considerable proportion of iron ore deposits is the result of the decomposition of sulphide of iron in one or other of its forms.

Since iron pyrite is of such commercial importance, being the chief source of the world's supply of sulphuric acid upon which so many of the chemical industries depend, it may be well to discuss the changes which occur during the weathering of this mineral, and their important and far-reaching results.

This subject has received considerable attention since before the time of Henckel, whose 'Pyritologia, or a History of the Pyrites, the Principal Body in the Mineral Kingdom', published in Germany over 150 years ago, states that hot baths, volcanoes, and whirlpools "derive their matter from pyrites and sulphur." Most interesting work in connection with the oxidation of pyrite has been accomplished during the last twenty years, the introduction of the cyanide process for gold extraction having made such investigations an absolute necessity. So thoroughly has this been done that, at the present time, the number of minerals which are either directly or indirectly credited, by both practical man and theorist, with a pyritic parentage, is legion.

Briefly stated, the result of the weathering of iron pyrite is the production of ferrous sulphate and free sulphuric acid, followed by the oxidation of the ferrous to normal, and ultimately, to basic ferric sulphate. With certain kinds of iron pyrite—notably marcasite—the decomposition proceeds with great rapidity, a clean specimen soon becoming coated with minute crystals of ferrous sulphate even when enclosed in a mineral cabinet. The sulphates so pro-

duced are mainly carried away in solution or suspension, but a small quantity usually remains, and, by final conversion into oxide, reddens the mineral mass from which the pyrite has been leached out. Should gold be present in the solutions acting upon the pyrite, the reducing action of the ferrous sulphate precipitates it as metal, producing oxidized ferruginous gold ore. The presence of extremely minute traces of gold in many saline and other natural waters is well known, and, although this store of precious metal will most certainly never be profitably tapped by mankind, nature is continually drawing from it and depositing the gold in concentrated and therefore available forms.

Enormous quantities of pyritic ores containing the precious metal exist under conditions which altogether preclude such an explanation of the deposition, but the fact that the rich surface indications of a gold mine are by no means a sign of continuance in depth (as would be the case were the gold merely left behind by the weathering of pyrite already containing it) is a significant proof of the frequent deposition of gold from surface and other waters.

As already indicated, the products from the weathering of pyrite have caused much trouble in the application of the cyanide process to gold ores. Being especially suited to ores containing the precious metal in a finely divided condition, the cyanide process is widely employed in the treatment of pyritic gold ores, and particularly of the tailing, from which the coarse gold has already been extracted.

In addition to their far-reaching effects upon the igneous and other rocks already referred to, the soluble products from the weathering of pyrite also react upon such carbonates and other compounds of lime, magnesia, alumina, etc., as they come into contact with, producing the corresponding sulphates. The carbonate of iron produced from such interaction, may be directly deposited as chalybite or spathic iron ore, but is more commonly converted, by loss of carbonic acid and subsequent oxidation, into various forms of ferric hydrate or oxide, such as limonite and hematite.

The familiar rusty iron stain which settles from chalybeate waters, affords an indication of the manner in which such ores have been produced, and the thick brown mud so frequently found in disused mines, are further examples.

The natural or induced weathering of iron pyrite is taken advantage of in the case of low-grade cupriferous iron pyrite at the Rio Tinto mine, both metals being dissolved out as sulphate and the copper finally precipitated as metal by treatment with pig or scrap iron. It is interesting to note that the Rio Tinto ore is one of the very few which lend themselves to such weathering. Many large deposits exist, which, although very similar in appearance, are almost incapable of such weathering, and, being too poor for smelting, have had to be abandoned.

Although Henckel's views as to the effect of pyrite were too advanced, there is probably no mineral on which so many industries depend or which yields so many direct or indirect by-products of commercial value. Although not a tenth of the total sulphur mined yearly in the form of pyrite, and practically none of that existing in other minerals, is utilized, the remainder passing into the atmosphere or being otherwise directly lost, nearly 2,000,000 tons of iron pyrite averaging about 45% sulphur, is annually mined, as a source of sulphur, mainly for utilization in the manufacture of sulphuric acid. This huge supply is supplemented by a comparatively small return of sulphur recovered from alkali waste by the Claus-Chance process, and particularly by the large amounts of native sulphur mined in Italy and probably attributable to natural processes acting on sulphurous gases somewhat as the Claus-Chance process, and by the rapidly increasing output of Louisiana. The two latter sources account between them, for about three quarters of a million tons of crude native sulphur annually.

Selenium occurs, although only in minute quantities, in native sulphur and in all pyritic ores, and becomes concentrated throughout various stages of their treatment. Its production as a by-product of sulphuric acid manufacture is well known, but its latest and principal source is the anode mud or slime from the electrolytic purification of crude copper. Although its percentage in the cupriferous pyritic ores from which the bulk of the world's copper is obtained, is so small that it cannot usually be determined, it becomes to a large extent concentrated with the copper through the various stages of treatment, and when one remembers that the bulk of the world's copper is purified by that process and that most of the selenium becomes accumulated in the mud left by solution of the anodes, the possibilities as to supply of selenium, should the demand increase, will be readily realized. Not only do these anode residues contain selenium; they contain often as much as 50% of their weight of gold and silver, together with much bismuth, all similarly concentrated by the selective power of metallic copper from the otherwise non-recoverable traces which occur in the original ore, and all obtained as true by-products by a treatment which would be necessary in most cases even were they not present. As regards bismuth, it may be noted that, in addition to the amount recoverable from the copper, over 800 lb. is stated to escape daily from the smoke-stack of a single copper smelter, the Washoe smelter of Montana, and that bismuth is now obtained from the anode mud in electrolytic refining of lead bullion.

Discovery from time to time of new gold-placer deposits in Alaska helps to maintain the general interest in that region and to give it importance in connection with monetary conditions and prospects. So long as gold is almost universally the basis of money, and so long as it is generally available for free coinage, its rate of production will be a matter of primary importance in the world of finance. The question whether the present high prices of many kinds of products are properly chargeable to the use of gold as a measure of values and to its free coinage, as some eminent students of finance have contended, or to other causes, may easily provoke warm discussion, but whatever may be the final judgment on this question, the immense gold output of Alaska must still command interest.

Paracale and Mambulao Districts.

By Warren D. Smith.

*This district comprises roughly 400 square kilometres of country of moderate relief. The topography is marked by a number of hills which extend outward as spurs from the cordillera, and have approximately a north and south trend. Between these hills are broad valleys largely filled with nipa and mangrove swamps. The whole country is densely wooded. The most elevated point is Mount Bonotán, about 500 metres high. Metamorphic rocks are a prominent feature of this area. The formations are pyroxenite, schist, granite-gneiss, granite, shale, sandstone, and andesite from north to south in the order named. The strike of the sedimentaries is roughly east and west, and they now stand nearly on end.

Prior to the Miocene disturbance, which flexed these formations into a nearly vertical position, the section of strata was probably as follows: at the base a pyroxenite and diorite complex; above this sandstone, shales, and possibly limestone; with andesite overlying. With the Miocene uplift came the intrusion of granite. Exposures of the granite cutting across the basic rock can be seen. Along the contact of the two, gneiss and schist were developed. Later, and probably before the outflow of andesite lava, there began a period of vein filling and ore deposition. Naturally, the principal deposition took place along the weak zone of the contact, and in the adjacent fractures. The principal lodes today are found along this granite-diorite contact and in the irregular fractures in the granite near its border. The placer deposits are found along the rivers which cut across these veins, and are naturally richer near them. When the last annual bulletin was published there was only one dredge in operation in the Mambulao district, and all the lodes remained practically as the natives and the former Spanish and English operators, the Philippine Mineral Syndicate, had left them. Eight months ago there were only the old workings of the syndicate in this part of the district, and a few recent shafts and tunnels as assessment work. I shall not discuss the innumerable shafts and tunnels, ancient workings dating from before the Spanish Conquest, with which the country is honeycombed. Since that time two companies, the Tumbaga and San Mauricio, have been getting ready for immediate operation.

Dredging Ground on Paracale River.

Tumbaga lies two and one-half kilometres south of the town of Mambulao. The orebody is in a brecciated zone between andesite porphyry and sandstone. The trend of the orebody is northeast. In this there is some slate through which innumerable calcite stringers ramify. Some of these stringers carry free gold; possibly all of the gold may be found to lie in these innumerable veinlets cutting the slate. Mr. Cavender, the superintendent, has opened up 305 ft. of drifts and cross-cuts, most of which is new work, also a shaft over 50 ft. deep, and has constructed a drainage tunnel of 355 ft. long. He has also, assisted by Mr. Collins, put into working order the old plant, parts of which were missing, and the remainder in considerable disorder, so that he was

*From advance report to Bureau of Science, Philippine Islands.

able to make a test-run on his ore. The plant as it now stands consists of the following: one Blake crusher; one 5-ft. Huntington mill, having a capacity of from 12 to 30 tons per day; two Johnson concentrators; besides the usual accessories, boilers, hoisting drums, skips, and the like.

Although the mineralized zone in places attains a width of 35 ft., this is not constant. The orebody is lenticular. According to Mr. Cavender, a trial run of 22 hours was made with this plant in November last. Eleven tons of ore were treated with the result that 93.6 oz. were cleaned up, which represented merely the free milling part of the ore. The concentrate has not been treated. If these figures are correct, as I have no reason to doubt, this ore contains some rich streaks.

The San Mauricio property is just one kilometre from Mambulao, on the hill to the east of the town. The orebody is a quartz filling along the contact between the granite and the basal rock, which here is more nearly a diorite than a pyroxenite. There has been a total of about 1000 ft. of drifts and cross-cuts opened, part of which represent old workings, and part extensions made by the present company, the superintendent of which is Mr. Blake. Besides this development work there has been erected a 20-stamp Traylor mill consisting of the following: 20 Traylor stamps, Blake crushers, Challenge feeders, and 8 Traylor concentrators. The stamps are 1050 lb. each, and it is proposed to have them dropped at the rate of 94 per minute through a 5-in. drop. This mill for completeness, general plan, and the way it has been set up, should be a model for future mills in these islands. In October, 1909, a severe baguio struck this coast and did damage to all the properties. At the San Mauricio the head-frame was blown down, but no other serious damage was done. It is not my intention to go much into detail in discussing the rocks and ores of this property, as it is planned to have a detailed study of the district made during the coming year by members of this division.

Other lode properties on which development work has been carried on are: Dinaanan, north of San Mauricio; the Le Duee property, southwest of Mambulao, and the group of claims known as the Iron King, Gordon, Isla, Guinto, Abe Lincoln, and Navotas, a different property, all a short distance east of Tumbaga. These are all promising prospects.

The history of operations in Paracale is quite different from that of Mambulao. Here the present operations are confined almost entirely to placers. The early history of Paracale has been written many times, so that I shall merely mention the progress made since the last report of the Division of Mines.

Two more dredges have begun operations above the Paracale dredge. The Stanley dredge farthest up the river is a New Zealand model, operated by New Zealanders. The Philippine dredge is of Risdon make and was operated by an American company. The hull for the fourth dredge is almost completed and plans for a fifth are under way. Of three dredges on the river, the two New Zealand ones are running steadily, but I regret to say that the third, up to the present time, has failed to get results, and has temporarily ceased operating. The Paracale Extension is a new company which plans to work ground farther up the Paracale river above the Stanley. The services of Mr. Kane, formerly dredge-master of the Paracale company, have been secured. The ground was being tested when I was in the district, and I witnessed some of the work. Most of the ground on the Paracale and Malaguit rivers has been tested and staked. However, there are no operations on the latter as yet. These rivers lie in broad valleys, covered with mangrove and nipa, through which the dredges work their way. The mangrove is used for firewood, and the nipa is either thrown aside or used by the natives for house-building. A test-hole in an adjacent river, which serves to give a general idea of the ground to be dredged, showed the following strata: soil, nipa, etc., to 5 ft.; sand and gravel, with some gold, from 5 to 25 ft.; heavy black loam, with considerable decayed vegetable matter, from 25 to 38 ft.; gravel, pay-streak, from 38 to 40 ft. The bedrock is a white decomposed granite and gneiss.

In some localities the bedrock varies between 10 and 60 ft. deep. In the last few months testing has been active. One party tested along the Tabas, Malaguit, Malagbang, Bosigon, Gumaas, Bulalakao, Mambulao, Colombayungon, Tigbi, Maniloc, and Ponso rivers. Other parties have carried on extensive boring in the Malaguit river; one company putting down over 300 holes. This gives only a small proportion of the testing in progress. The Paracale river, of course, is the most thoroughly tested field.

In the forthcoming bulletin of the Mineral Resources I shall describe somewhat in detail the types of dredges. The ground being worked by the dredges now in operation is unusually rich, in one case ₱2 per cubic yard, according to the dredge-master's sworn statement. It is not likely that such richness will be found in all, or even in many parts of the district. The concentration at certain spots is due to the fact that the river cuts across the veins in these places. This can be easily and clearly seen by an examination of the field relations and of the fresh, crystallized gold as it is caught on the dredge. While this richness may not be maintained throughout the district, there is not much doubt that a great deal of profitable ground exists in the district and that there is room for more dredges. Just at present the labor conditions in Paracale are not entirely satisfactory. In other places I have gone into the reasons for this and do not care to repeat them at this time. The Camarines coast is but sparcely settled and but little opened by commerce. The conditions ought to improve.

It is necessary at this time and in this place to make a general statement which undoubtedly will provoke some criticism; however, I firmly believe that the public which helps to pay for these operations has a right to know the general status of the industry. One dredge is lying idle because of insufficient knowledge of conditions, and a mill has been put up before sufficient development work was done. This jumping without looking ahead or backward has characterized many of our mining operations in the past. Masbate has suffered from it, but happily has recovered, and has made a good start in the right direction.

Pachuca District, Mexico.

Written for the MINING AND SCIENTIFIC PRESS
By J. LESLIE MENNELL.

The centre of greatest mining interest in Mexico at present, is the famous old Pachuca district; and there is little doubt that during the next few years it will enjoy a 'boom' unprecedented in Mexican mining history. It is a very old mining town, indeed, one of the first worked by the Spaniards, and it has for more than 300 years been a constant producer of silver of great importance. It was the metallurgical problem of extracting the silver from the sulphide ores of Pachuca that gave birth to the old 'patio' process, invented by Bartolome de Medina in the middle of the sixteenth century. This process gave good results in the extraction of the silver, often as much as 92 or 93% with some of the ores, and it assured thenceforth the profitable operation of the mines. During the succeeding centuries large amounts of silver were produced and a great name earned in the silver mining industry of Mexico.

The veins of the district are strong and wide, the

General View of Pachuca.

most important, the Vizcaina vein, averaging about 17 or 18 ft., and attaining in several places a size as great as 40 to 45 ft. in width. They have been traced on the outcrop over a great distance, the above-mentioned vein being distinctly shown for about 15 kilometres, and it has been worked by several companies over an extention of about 8 kilometres. Mining operations in depth have proved the orebodies to be persistent, richer and larger bodies having been found in the deep workings than near the surface. The deepest workings of the district are those of the Santa Gertrúdis Mining Co., which reach 1400 ft., and it is to be noted that orebodies were there developed equal in importance to any previously encountered. There are two systems of veins in the district, a north-south parallel system, or the 'Pachuca system' proper; and an east-west parallel system worked in the adjoining Real del Monte portion of the camp about six miles from Pachuca, to the north. The former system has to date proved to be the most important, but the east-west veins of Real del Monte have also produced enormous amounts of silver ore and have acquired great fame.

The exploitation of the mines during Spanish times and to the end of the nineteenth century continued apace and with great profit. English companies employing improved mining methods succeeded the Spanish workers in the early decades of the last century; and these were followed by Mexican companies that continued to work the mines under the old methods until a recent date. The operations were conducted upon an extensive scale, considering the conditions and facilities for mining, and the large size of the 'patios' required, as also the large number of men and animals and complications involved in the treatment of a large tonnage daily by the 'patio' process. Gradually, however, toward the close of the nineteenth century, the working of the mines under the old conditions became less profitable, and the district suffered a depression. Various circumstances combined to bring about this unfortunate result. On the one hand the costs of operation became increasingly greater, owing to the expense of mining at greater depth without modern machinery; as also the greater costs of the already expensive patio and pan-amalgamation processes, due to the rise in the cost of materials and labor.

A Pachuca Mill

On the other hand the gradually decreasing price of silver diminished the value of the output.

These conditions depressed the operations of the district until quite recently, when the successful application of the cyanide process to the treatment of ores solved the main difficulty. The re-awakening began in 1906, closely following the adoption of the cyanide process for the treatment of the Guanajuato ores in 1905. No sooner had the process proved successful in the latter camp, than experiments proved the Pachuca ores to be equally amenable to cyanide treatment, showing an extraction of 90 to 95% of the silver at a treatment cost of less than half that by the old patio process. The result was an immediate improvement in the district. The old Real del Monte y Pachuca mines were acquired by Americans and the old patio treatment of the ores at the Hacienda Loreto, in Pachuca, was discontinued, a modern cyanide plant, of a capacity to treat 250 tons of ore daily, being erected upon its site. The results of the treatment of the ores by cyanidation were a great success, and in consequence a second plant was erected by the same company near the Real del

Monte mines, namely, the Guerrero mill, which treats 300 tons of ore per day. This second plant is more efficient than the first, and the treatment has proved more economical also. The introduction of electric power into the camp, by the Cia. Eléctrica é Irrigadora de Hidalgo, also helped to cheapen power and facilitate the utilization of up-to-date mining and milling machinery in the several mines and mills of the district. With modern machinery to facilitate deep mining, with cheaper power, and the cyanide system of treatment cutting in half the costs previously incurred in the treatment of the ores by the patio system, the success of the mines and the speedy growth of the district to its old position among the important silver producers of Mexico, became assured. About the same time as the installation of the first plant by the Real del Monte company, the old Hacienda San Francisco erected a second custom-mill and cyanide plant to treat 125 tons daily, and this also was a great success. The Hacienda San Francisco No. 2 plant was the first in which the new system of agitation in 'Pachuca' tanks was used, and all plants since erected have followed its lead. These tanks have proved to be the most efficient and least costly agitators for slimed ores. Following the San Francisco mill, came the Union, also a custom-mill, a remodeled old plant in which was installed a cyanide annex. After this the San Rafael y Anexas company, working the famous Soledad mines, erected a 400-ton cyanide mill, and this is perhaps the most efficient plant in the district. The latest to be completed, and just now starting, is the Santa Gertrúdis Mining Co.'s plant, which has superseded the old patio plant at the Guadalupe hacienda in Pachuca. A second plant is being designed and will soon be erected by the same company near the mines. The site for a large plant is also in preparation by the Blanca Mining Company.

There are now installed in the Pachuca district six large modern cyanide plants, with a capacity of about 1500 tons per day, and two other plants are being installed. All of these are making large profits. All this progress has been the work of the last four years, the introduction of the cyanide process having been the main factor. Previously ores of less than 1000 gm. silver per ton were discarded on the dump, while ores of 500 gm. are now capable of giving good profits. This has made many of the large dumps valuable. Many of the old mines contain large amounts of 'filling' of that grade ore, and it is now being extracted and treated in the modern mills.

In consequence of such improved conditions, and of the great success in the adaptation of the cyanide process here, interest in the district is increasing rapidly. The recent purchase of the Santa Gertrúdis mines by the Camp Bird company has greatly accelerated this, and companies are being formed to take over other old mines. Also development companies are opening new ground in the same district. Much of this large system of veins is still virgin, or has been worked only superficially.

Coals containing the highest percentage of fixed carbon give the least smoke and are also the most efficient heat producers.

EFFICIENCY OF HEAT DRYERS.

By W. B. Ruggles.

*To determine the total efficiency of a dryer using direct heat is a simple matter, but to discover where the losses occur is not so easy. There are four sources of loss—unconsumed carbon, due to imperfect combustion; heat carried out by the exhaust gases; unnecessary heat carried away by the dried material; and radiation from the furnace and shell.

The first of these is generally ignored, this loss being charged against radiation. Recent tests, however, have shown it to be a considerable factor, unless a large combustion chamber is supplied, in which space and time are given for the perfect combination of oxygen with the carbon monoxide. When the dryer is so arranged that the flames impinge directly upon a cascade of cold and wet material they are quenched suddenly and a considerable amount of carbon passes off unconsumed. This, in certain types of machines, may amount to 7 or 8% of the value of the fuel.

The heat carried out by the exhaust gases is generally the largest item of the losses, and sometimes amounts to 30% or more. This occurs in dryers in which natural draught is relied upon to burn the fuel. As in a steam boiler, the temperature of the stack gases in such a dryer is seldom below 400°F., and is often 600° or more. It is easy to see that a dryer which utilizes, for instance, the 1200° between 1300 and 100° is, other things being equal, about 50% more efficient than one utilizing only the 800° between 1300 and 500°. In order to get as much of the heat out of the gases as possible, it is necessary to use an exhaust fan and draw the gases against the flow of drying material, so that just before leaving the dryer it has been in contact with the cold and wet material. Undoubtedly some condensation occurs of the steam being carried out; but there is no ultimate loss, as the heat given up in condensation is absorbed by the material and aids in drying later in the process. When the current of the gases is reversed and flows in the same direction as the material, a temperature of at least 212°F. must be had in the exhaust, so that no condensation may occur and no moisture deposited upon the furnished material.

The heat carried out with the dried material up to 212° should not be charged against the efficiency of the dryer, as that temperature is necessary to the rapid drying of the material. All heat of the material above 212°, however, is unnecessary in most operations, and, therefore, should be charged as a loss. This is generally not great, and is, in most cases, due to imperfect operation and not to the design of the machine.

Radiation varies greatly in different types of dryers. In some, the shell is cool enough to place the hand on without discomfort; in others, it is not uncommon to see the shell red-hot for 10 to 12 ft. from the furnace. This, of course, is in a single-shell type, in which the flames impinge directly upon the shell. The loss by radiation in such a dryer is great.

*Abstract from *Cassier's Magazine.*

Canadian Mining Institute, Toronto Meeting.

Written for the Mining and Scientific Press
By Phillips Thompson.

The twelfth annual meeting of the Canadian Mining Institute was held March 2 to 4, at the King Edward hotel, Toronto, the attendance being large. The chair was occupied by Willet G. Miller, the president, who opened the proceedings with a comprehensive inaugural address, reviewing the growth and history of the Institute, and dealing with the condition and outlook of the mining and metallurgical industries. Noting the tendency toward the consolidation of interests by large industrial companies, he contended that this should make for increased efficiency and economy in management and operation. The progress of mining in late years was shown by the fact that it was the second of the staple industries of Canada in the value of its product. Dealing with the subject of mining legislation, Mr. Miller considered the mining laws of Mexico as almost ideal. He was disposed to favor an annual acreage-tax on mineral lands, rather than the imposition of working conditions, as a means of preventing the 'blanketing' of claims and holding for speculation, and he pointed out that such extensive blanketing, which was encouraged by permitting the staking by proxy, reacted against the prospector by putting too many claims on the market, many of them valueless. In the taxation of mining a distinction should be drawn between it and other forms of production, as the net earnings of a mine largely represent capital, and should not be taxed like other sources of income of a more permanent character. He alluded to recent utterances of Clifford Sifton, chairman of the Canadian Conservation Commission, who had stated that mining accidents were more numerous where there were many small mines or prospects in the early stages of development, than when operations were conducted on a larger scale. The question of explosives should be taken up by the Federal Government, which should also deal with the matter of technical education. A keen discussion followed, and a resolution moved by R. W. Brigstock, of Cobalt, and seconded by J. E. Hardman, of Montreal, expressing regret that the chairman of the Conservation Commission should have made statements reflecting on the mining and metallurgical practices of Canadian companies without being acquainted with the facts, was adopted.

The report of the Council showed an accession of 97 members during the year, and a total membership of 935. The financial statement showed receipts of $10,497, and a balance on hand of $1452. The election of officers resulted as follows: president, Frank D. Adams, McGill University, Montreal; vice-presidents, A. B. W. Hodges, Grand Forks, B. C., and R. W. Leonard, St. Catharines, Ontario; councillors, Selwyn G. Blaylock, Moyle, British Columbia; Robert A. Bryce, Cobalt; Arthur A. Cole, Cobalt; John A. Dresser, Ottawa; Charles Fergie, Montreal; R. T. Hopper, Montreal; G. G. S. Lindsey; Toronto; J. J. Penhale, Sherbrooke, Quebec; J. B. Tyrrell, Toronto; and O. E. S. Whiteside, Coleman, Alberta.

John McLeish, chief of the Division of Mineral Resources and Statistics, Canadian Mines Department, presented a preliminary report on the mineral production of Canada for 1909, showing the value of metallic products to be $45,188,387; non-metallic, $44,927,376; estimated value of mineral products not reported, $300,000; total, $90,415,763, compared with a total value for 1908 of $85,927,802. This gives an increase of a little over 5%. The metals nearly all showed an increased output. Among individual products coal was the most important, its value constituting 27% of the total, and silver occupied the second place with 15%. Complete statistics for gold were not available, the preliminary estimate of $9,790,000 revealing a slight decrease. Of silver, 27,878,590 oz. were produced, valued at $14,358,310; as against 22,106,233 oz., of a value of $11,686,239 in 1908. The production of Cobalt district showed a considerable increase. Returns from 31 mines showed shipments of 28,042 tons of ore and 2967 tons of concentrate. The total silver content of the ore, concentrate, and bullion shipped was 26,364,703 oz. The production of copper contained in blister and matte, and estimated as recoverable from ores exported, was approximately 54,061,106 lb., valued at $7,018,213, an increase in production of about 2%. The output of lead was 45,857,424 lb., valued at $5,832,246, and the value of the zinc product was estimated at $250,000. The nickel industry was particularly active, and the output was the largest on record, namely, 26,282,991 lb., valued at $9,461,877, as against 19,143,111 lb. in 1908, valued at $8,231,538. The shipments of iron ore amounted to 268,043 tons, valued at $659,120, as against 238,082 tons and $568,189 in the previous year. The ores were classed as magnetite 73,420 tons, hematite 190,473 tons, bog ore 3330 tons, and titaniferous magnetite (sand) 820 tons. An increase of 20% was shown in the production of pig iron, the total being 757,162 tons, valued at $9,581,864, as compared with 630,835 tons, valued at $8,111,194 in 1908. These figures do not include the output from electric furnace plants making ferro products. Of the output of 1909, 17,003 tons were made with charcoal as fuel, and the remainder with coke. The amount of Canadian ore used was 231,994 tons, imported ore 1,234,990, and mill-cinders, 25,508 tons. The total daily capacity of 16 completed furnaces was 2735 tons, and the number of furnaces in blast on December 31 was 11. Returns were received from 8 steel plants, showing a total production of ingots and castings of 754,719 tons, of an estimated value of $14,359,710, as compared with 754,719 tons, valued at $10,916,602 in 1908. The total bounties paid on iron and steel during the year amounted to $1,895,011. Coal was produced to an estimated amount of 10,411,955 tons, valued at $24,431,351, being a smaller production than in either of the two preceding years. The western Provinces show an aggregate increase of 505,404, which was not sufficient to counteract the decrease of the Nova Scotia output, amounting to 968,789 tons, owing to the miners' strike. The aggregate decrease for Canada was 474,356 tons. Of the total production Nova Scotia

contributed 54.5%, Sawkatchewan and Alberta 205, and British Columbia 24.5. The production of oven coke was 875,080 tons, valued at $3,557,147, being a slight increase. Full returns as to cement were not received, but, subject to correction, the output is given as 4,089,191 bbl., compared with 3,495,961 in 1908. Statistics of the year's production of the Provinces of Ontario, Quebec, Nova Scotia, Alberta, and British Columbia were also presented. The returns from the Department of Mines of Ontario showed a production having a total value of $32,652,072, as compared with $25,637,617 in 1908.

H. Mortimer-Lamb, the secretary of the Institute, read a paper by J. D. Kendall, of London, England, on 'Mining Engineers and Mining Institutes', in which he advocated the establishment of a mining institute by law in every mining country, to which every person practising as a mining engineer should be compelled to belong after having passed a satisfactory examination as to competency and character. R. W. Brock, of Ottawa, presented a paper on 'The Necessity of Distinguishing Between Prospecting, Developing, and Mining'. He dwelt strongly on the manner in which the legitimate mining industry was handicapped by 'wild-catting', money which should be devoted to development being diverted to unscrupulous promoters. The failure of wild-cat projects deterred investors from putting money into legitimate enterprises. He had not much faith in legislation as a remedy. The public must be educated to protect itself by using discretion. Instead of regarding any claim as a 'mine' the investor must learn to distinguish between claims, prospects, and mines. If this difference were generally realized the investments in mining would be greatly increased. A paper on 'Mining Literature', by Allan Greenwell, of London, England, was read by Frederick Hobart, of New York. L. L. Bolton, of Sault Ste. Marie, Ontario, read a paper prepared by R. W. Seelye, of the same place, on 'The Helen Mine, Michipicoten', which, in addition to giving an interesting account of the history, present condition, and equipment of the mine, contained important information in regard to recent discoveries which considerably increase the value of the property. The length of the hematite deposit is 700 ft. and the line of greatest dimension runs east and west. At the end it is bounded by siderite containing 34% or more of iron, and at the west end the iron deposit is cut by a white clayey dike running north and south. Exploratory work was undertaken last year, and on driving west at the third level, after crossing the clay dike, a body of hard red hematite was found, which on analysis proved to be high-grade bessemer ore with the following content: iron 60%, silica 9.7, sulphur 0.05, phosphorus 0.03. A smaller parallel body of siliceous bessemer ore was tapped 60 ft. to the north, showing on analysis, iron 50%, silica 25, sulphur 0.07, phosphorus 0.035. Driving undertaken at the fourth level, beneath the third level adit, also cut bessemer hematite, and the ore was being blocked out and preparations made for working at deeper levels. Explorations of the ground to the east, where the merchantable ore changes to low-grade pyritic matter, were also undertaken, and after 30 ft. of driving on the fifth level, a deposit of clean hard pyrite was encountered. On February 15 the drift had passed through 150 ft. of this material, and cross-cutting proved the occurrence of a large deposit of high-grade pyrite. Raises were being put in so that it might be ready for stoping on the opening of navigation. Analysis showed 49% sulphur and a trace of arsenic. Hitherto the mine had shipped only one grade of ore, but during the coming season three grades would be shipped, and in addition arrangements were being made for mining 50,000 tons of pyrite for spring delivery. The entire output of ore would be taken by the Algoma Steel Co. The total shipments of ore during the history of the mine amounted to 1,673,915 tons, and last year's shipments were 170,065 tons.

'The Iron Ore Deposits of Texada and Vancouver Islands' were dealt with by E. Lindeman, of the Mines Branch, Canadian Department of Mines, who in 1907 made an inspection of these deposits. He stated that, as a rule, the iron content of the magnetites is high, averaging about 55 to 60%, and sometimes reaching 68%. The phosphorus content is generally below the bessemer limit, and the silver varies from 4 to 8%. Sulphides of iron are often found, and may in some places render the roasting of ores necessary. The surface area of the deposits varies up to 30,000 sq. ft. The deposit on Texada island had been proved to a depth of 430 ft. Of the properties on this island the Prescott had been most extensively developed, and had shipped largely to Irondale, Washington. Detail descriptions of the workings of leading properties, with analyses, were given. Though it is impossible at present to make an approximate estimate of the ore in sight, there is a possibility of large quantities of merchantable ore being found.

At the evening session papers were read by P. McN. Bennie, Niagara Falls, New York, on 'Recent Developments in Electro-Siderurgy', and 'Steel from the Electric Furnace', by A. Stansfield, of Montreal.

On Thursday, March 3, the proceedings were opened with the delivery of an address by A. E. Barlow, of Montreal, on the origin of asbestos, his contention being that the material in asbestos veins was not brought from a distance, but resulted from the alteration of the rock in place, being an attempt at the crystallization of the serpentine.

John A. Dresser, of Ottawa, followed with a paper on 'The Distribution of the Chromite and Asbestos Deposits of the Eastern Townships'. These deposits were associated in the same rocks. Asbestos was produced in Canada to the value of $2,500,000 annually. It was produced 30 years ago in commercially valuable quantities, but its high cost prevented its general use. In 1893-94, however, the mine-managers undertook mechanical concentration, and large quantities of lower-grade were placed on the market, resulting in a great expansion of the industry, stimulating new discoveries. Asbestos being of the same chemical composition as the serpentine enclosing it no analysis could determine its value, and the rocks were obscure and difficult to determine. There were three main ranges of these rocks in the district southeast of the St. Lawrence generally known as the ser-

pentine belt. The asbestos mines were generally at the foot or on the side of the serpentine hills, and always to the north. The features to be looked for in prospecting for asbestos were the purity of the serpentine and the fracturing of the rock. It was generally considered that the presence of granite was necessary, but this was not invariably the case, though granite was favorable to the occurrence of asbestos.

F. L. Ransome, of the U. S. Geological Survey, Washington, D. C., read an elaborate paper on 'Criteria of Downward Sulphide Enrichment'.

Amendments to the by-laws were proposed, limiting the membership to those having been engaged for five years in practical mining or metallurgical work. After a lengthy discussion, which developed strong opposition to the proposal, it was voted down. Another amendment for the appointment of a nominating committee to choose the officers was also defeated.

Dr. James Douglas, of New York, presented a paper on 'Some Reminiscences of Copper Mining in Megantic county, Quebec, and the Possible Present Utilization of Low-Grade Quebec Copper Ores', which was optimistic in tone. He thought that improved methods of mining, and the extension of the railroad system, would enable many of the Quebec copper mines, now abandoned, to be profitably worked. The policy of restricting the exportation of pulp-wood and building up a pulp manufacturing industry, should lead to the utilization of the sulphur found in low-grade ore in the manufacture of sulphide pulp.

A smoking concert was held in the evening, G. G. S. Lindsey presiding, and J. D. Irving, New Haven, Connecticut, read a paper on the 'Formation of Ore Deposits by Displacement'. Among the papers presented at the session on Friday was one by Charles Camsell, of Ottawa, on 'Platinum Mining in the Tulameen District'. The history of platinum mining in this district dates from 1885, the metal being derived from the placers. In the early days little attention was paid to it, but when the price advanced sufficiently to make it worth while it was saved in cleaning up the gold. Previous to 1891 the miners were without capital, working singly or in small groups. Since that time several hydraulic enterprises were carried on, but these were not successful, and within the last four or five years placer mining in the district has only been actively continued by a few individuals. A company recently organized in Vancouver, the British Columbia Platinum Co., has obtained from the Provincial Government three leases in what was formerly the most productive platinum district. It was proposed to prospect the ground with a Keystone drill, and mine by ground-sluicing or drifting on bedrock. Much of the gold and platinum of the district is coarse, and has the rough unworn surface characteristic of nuggets which have not traveled far from their source. The ultimate source of the placer platinum must have been the solid rocks which underlie and are adjacent. The platinum-bearing tributaries of the Tulameen river are Slate creek, where the richest diggings were found; Cedar, Eagle, and Bear creeks, with Granite creek and its western branches. All these, except Cedar creek, have their origin in, or they cut through, a belt of basic rock running from the head of Newton creek at Lodestone mountain northward across the Tulameen. It has been concluded that here must be the source of the platinum. In the Tulameen district the nuggets of this metal are invariably small, and I have not heard of any whose weight exceeded half an ounce. Figures bearing on the total production of platinum from this district are incomplete, and details are difficult to obtain. Much of the placer mining is done by Chinese from whom reliable data cannot be procured. So far as at present known the mineral does not occur in commercial quantities anywhere except in the placers. There are probably placers in the district that would repay a reasonable outlay of capital in an endeavor to recover the platinum.

The annual dinner of the Institute was held on Friday evening at the King Edward hotel.

COLD-STRAIN IN PIPING.

Cold-strain is a method for reducing the effects of expansion on a pipe-line. Cold-strain means the cutting of the pipe in such a manner that the pipe will be strained when cold in exactly the opposite way from that in which it is strained by expansion when hot. If the cold-strain be 50% of the normal expansion, the pipe will be strained 50% in the opposite or positive direction when hot. By this means it is possible to reduce the strain in a pipe to half the normal strain of expansion, and thus reduce the necessary allowance for the same in this proportion. There are advantages, however, in making the cold-strain greater than 50%. If, for instance, the cold-strain is exactly equal to the expansion, then the pipe is under strain when cold, and entirely free from strain when hot, or, in other words, the tendency to strain open one side of a pipe-flange is a maximum when the pipe is cold or when there is no pressure on it. The strain of expansion is also eliminated when that due to steam-pressure is a maximum, so that the pipe is not subjected to the two strains at the same time. If the cold-strain be something less than the full expansion, these effects are, of course, proportionately decreased. An example will show how cold-strain was utilized to prevent serious trouble. A leak in one of the main steam-pipes in a large hotel was causing great annoyance. It was due to the flanges being thrown out of line by the strain of the expansion of the piping. It was of the utmost importance not to shut off the steam from the pipes for more than a short time. It was suggested by William J. Baldwin that one length of flanged pipe be replaced by a similar piece of pipe, but cut enough shorter to eliminate entirely the excessive strain of expansion when the piping was hot. This new piece of pipe was made ready before the plant was shut down, and the time, therefore, during which it was not in operation was limited to a few minutes. Another advantage of cold-strain is that wherever flanged piping is used the flange-joint when unbolted will tend to open and allow an easy removal of the gasket.—*Proceedings* American Society of Civil Engineers.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Qualified Mining Engineer.

The Editor:

Sir—A letter in your issue of December 11, from John M. Nicol, again brings up the question of the qualifications necessary before a man have the privilege to sign and practise as a mining engineer. Mr. Nicol suggests examinations from time to time, each being more rigorous and searching than the last, such examinations to carry with them diplomas of increasing value. I quite agree with Mr. Nicol that a university graduate is merely an engineer still in process, but cannot accept his suggestion for differentiating the qualified from the unqualified engineer.

A university degree should not entitle a man to consideration as a mining engineer for the simple reason that university training alone does not make an engineer. All it does is to help elucidate some of nature's fundamental laws, impress the graduate with the dignity of his profession, and train his mind to reason logically, both analytically and synthetically. With this advantage over the non-graduate, the graduate is prepared to go into the field, and by observation and instruction from his superiors, to assimilate engineering knowledge of commercial value. His judgment is developed, and among his fellows he will soon find his level, while in the majority of cases his advancement will be a measure of his ability as an engineer.

It seems reasonable to suppose that the opinion formed of such a man by those in intimate contact with him and his work will be a better measure of his ability than any amount of cross-examination. In fact, it forms the best possible evidence for judgment as to his character, ability, and the many requirements for the making of an engineer. Would it not be a good plan to expand such a principle, and apply it to mining engineers as a body? This could, I think, be accomplished by the engineering societies. It is interesting to consider conditions governing physicians and surgeons in Canada. A degree of Doctor of Medicine from certain recognized colleges, carries with it a right to practise medicine, not by virtue of the degree alone, but because the degree covers membership in the Society of Physicians and Surgeons, and this membership gives a legal right to practise. These bodies are, as yet, provincial, but I have no doubt they will in time become national in character.

Applying this principle to engineering, I again quote a Canadian institution, as I am not familiar with the engineering societies in the United States. There is in Canada, the Canadian Society of Civil Engineers, embracing mining, mechanical, electrical, and civil engineers; this latter being used in its restricted sense, whereas the word 'civil' in the Society's name is in contradistinction to the word 'military'. Membership in the Society is of different grades, according to the record of the applicant, and is open to professional men only. I do not mean that a university training is necessary or even desirable, but it is absolutely essential that a man be an engineer in the strict sense of the word before he be allowed active membership.

A graduate in engineering of a university of the highest standard cannot become a member until after a definite period of professional responsibility and a record of some ability behind him. A man's training, whether wholly academic or wholly practical, is not the criterion by which his ability is judged; his works, and the opinions of his fellows, determining whether he shall or shall not gain professional standing in the Society. The result of such a policy is, among other things, a society, the members of which are recognized as men thoroughly qualified to practise engineering as a profession.

Confining my remarks to mining engineering, I think most engineers will agree that if only those who are really qualified to act as engineers; who possess the skill necessary to undertake the operation of a mine, and do so with the least loss or greatest profit; who are by their training, whether this be academic or practical, able intelligently to pass an opinion on a mining venture; who are, in a word, legitimate engineers entitled to recognition as such, were by law entitled to the distinction of being called mining engineer; to write E. M. after their names and to advertise themselves as such, then would the profession be put on a par with the other legally recognized professions.

If membership in an engineering society, similar in character to the one I have described, and national in its scope, were by law necessary before a man be entitled to write E. M. after his name, would this not be practicable, and would it not answer the purpose of differentiating the real engineer from the faker or the yet unfinished product? My suggestion is that it be made illegal and subject to penalties for any man to advertise as a mining engineer, unless he be a member of a society which has by its charter the right to grant such position.

The suggestion I make does not militate against the non-academic man; it draws no line between the graduate with a dozen degrees and the man with none at all, but it does effectually draw a sharp line between an engineer qualified to practise and the engineer still in the making.

The universities should be ready to adopt some plan to protect their graduates, and engineers to protect themselves and the public, against the untrained irresponsible man often miscalled an engineer.

Restricting the use of the title of 'mining engineer' does not prevent John Doe, 'mining expert', who is not eligible for membership, from taking a responsible mining position. It does not prevent him from reporting on a mining venture or proclaiming himself a mining man of international fame. It does not take from him his means of livelihood, but it does make him sail under his true colors, that is, a man who is not considered an engineer by those best able to judge.

Referring to the proposal to hold examinations, I

cannot see how these could be applied. Who would the examiners be? How many of the more eminent men in the profession would submit to what to them would seem the indignity of an examination? Finally, how can a man be examined to determine whether he is or is not a mining engineer?

ARCHIBALD BURNETT.

Greenwood, B. C., January 14.

Estimation of Cyanide in Mill Solutions.

The Editor:

Sir—In a communication in your issue of January 15, Algernon Del Mar points out the discrepancies between different authorities in the quantities of $AgNO_3$ recommended for making up the standard solution used in the estimation of KCN; he asks for the correct quantity for use in the practical work of a cyanide plant.

Mr. Del Mar's standard silver solution is that of which 1 c.c. titrated against a 10-c.c. sample is equivalent to 0.01% cyanide solution, 2 lb. per ton. The extremes on the list he gives are 13.076 and 13.036 gm. of $AgNO_3$ per litre of solution, a difference of four parts in 1300. Adopting the mean value as a standard, the greatest error involved in the use of a possibly incorrect standard is 2 in 1300, about 1½ in 1000. If then, a sample titrated against this mean standard is 0.01% KCN, 2 lb. per ton, it becomes in terms of the weakest 0.010015%, or 2.003 lb. per ton, and correspondingly less in terms of the strongest. But in the plant, cyanide is never weighed, nor can the solution be measured, with a degree of accuracy remotely approaching 1½ parts per 1000; therefore, the cyanide required for a plant can not and need not be known to 1½ lb., which is about 75c. in $500; furthermore, the end-reaction of the titration is often so obscure that a large error results; but the inaccuracy arising from these causes is not susceptible of exact computation.

Assuming that the cyanide can be weighed, the solution measured, and the end-reaction defined within any required degree of accuracy, there exists in the process of titration an inherent error which becomes important when small quantities of solution are used, for the accuracy of any titration varies inversely as the quantities of solution involved. A burette will usually deliver about 30 drops per c.c., rarely more; so one may say that it is an instrument sensitive, at most to $^1/_{30}$ cubic centimetre.

In practice a 10-c.c. sample is usually taken. If it requires, for the estimation of its KCN, 1 c.c. of standard silver-solution, equivalent to 0.01% KCN, there is a possible error involved of $^1/_{30}$, the strength of the sample lies between $1^{59}/_{60}$ and $2^1/_{60}$ lb. per ton; for a stronger or weaker sample the error is proportionately less or greater. The error for any given strength of mill-solution may be reduced by using a larger sample or a weaker standard, or both, for either expedient necessitates the use of more standard solution; thus by substituting a standard of which 1 c.c. equals 1 lb. per ton of KCN, the error is cut in half. Probably the average strength of the solution-samples of most cyanide plants is roughly 2 or 2½ lb. per ton. By use of the usual sample and 0.01% standard solution, the error ranges from 1 in 25 to 1 in 50, but the greatest error involved in the use of any of Mr. Del Mar's list of quantities is 1 in 650; hence, in using the most incorrect of these, to titrate even 5 lb. solution, there exists the ample safety-factor of 9.

It is necessary for scientific purposes that as nearly correct a standard as possible be ascertained, and having been established it is desirable that it be adhered to in technical work, if for no other reason than this, that it is just as easy to weigh out a correct quantity of $AgNO_3$ as any other; yet my answer to Mr. Del Mar's question is, that it is not of the smallest practical consequence which of the quantities he gives be used in a cyanide plant, for the burette can not discriminate between them.

J. E. COLLIE.

San Francisco, January 21.

Quicksilver at Huancavelica, Peru.

The Editor:

Sir—The comments on the amount of metallic mercury obtained direct as 'free metal' from the condensors have given interesting data regarding the Californian practice, where opportunity has existed for the study of the conditions which affect the high extractions obtained in using modern types of furnaces. In the Huancaveliea practice, in Peru, where crude furnaces and condensing arrangements were employed, there was evidently little or no attention paid to the character of the ore, and to other conditions which would account for the low extraction of 'free metal'. In the discussion the type of furnace used seems to have been overlooked as a basis of comparing extractions.

After a more leisurely reading of the paper, as it appeared in the issue of October 23, 1909, I note a few mistakes which need correcting. As regards the trip of the Archbishop—the phrase "in the very early days of the Spanish conquest" should have been included. Pizarro commenced his conquests in 1532. Referring to the Ulloa tunnel the word 'before' in place of 'below', in the phrase "at a depth of 500 metres before the Nuestra Señora de Belen," makes an entirely different sense. The diameter of the fire-box of the furnace should read 1.5 metres, not 15. Lastly, the total of the detailed costs from January 1 to June 3, 1792, should be 31,558 pesos and 6 reales, instead of 13,558 pesos and 6 reales.

LESTER W. STRAUSS.

Lima, Peru, February 13.

Precipitation of gold from cyanide solutions by electricity has long been practised, although it has not come into general use. The Siemens-Halske electro-precipitation process is employed to some extent. A description of this method will be found in any standard treatise on the cyanide process.

Bonanza ore is said to have been found in veins in the Ocoña quebrada in the Province of Camaná, Perú. The veins are of quartz, traversing zones of diorite. In old workings in that district considerable bodies of ore have recently been developed assaying more than 1 oz. gold per ton.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Driving in hard trap rock, under the most favorable conditions, at the New Bergen tunnel of the Pennsylvania railroad, during the record week reached a speed of 6 ft. per diem.

Primary solid decomposition product of feldspars consists of clay in a variable state of purity, depending on the nature of the original rock. During the decomposition, the alkalies or other bases are mainly carried away in solution.

Lithium exists in such great abundance in the deposits of spodumene in the Black Hills of South Dakota that no market for the output from other sources can be found. The enormous deposits of lithium minerals in southern California have long been unworked for lack of a market.

Nickel-steel for automobile construction contains about 0.2 to 0.25% carbon, 3.5 nickel, 0.6 to 0.9 manganese, with sulphur and phorphorus together not exceeding 0.04. A slightly lower carbon is sometimes used for case-hardening. This steel is especially suitable for heat-treatment and for case-hardening.

Shallow concrete beams require little provision for taking shear by any other means than the concrete itself. In slabs shear is seldom provided for in the steel reinforcement. Only when beams begin to have a depth approximating one-tenth of the span does shear in the concrete become excessive, when provision for it is necessary in steel reinforcement.

Concrete is being used extensively in place of canvas tables for concentration of sand tailing from gold mills. In preparing the concrete it is necessary to make tests to find the maximum size of sand that may be used in mixing with the cement so as to give the proper coarseness of grain suitable for the best concentrating surface with the particular tailing under treatment.

Oxygen-ratio in slag-making is the ratio between the oxygen of the base and of the acid. It bears a definite relation to the replacement-value of the base. The more oxygen there is in a base the greater will be its power to replace the acid, that is, to counterbalance the oxygen on the silica side of the slag. Therefore the more oxygen there is on the base-side of a possible ore-mixture, the more silicious ore can be added to the charge.

Boiler-scale is due to the deposition of carbonates and sulphates of the alkalies, lime, magnesia, and the like, together with earthy sediment carried in the boiler-feed water. This not only lessens the available water-space in the boiler, but, on account of the non-conducting properties of such incrustation, it reduces the boiler efficiency. A crust of $^1/_{16}$ in. of scale will reduce the evaporative efficiency 13%; ¼ in., 38; and ½ in., 60. The amount of deposit from 1000 gal. of water may be calculated by dividing by 7 the number of grains of salts in solution, as shown by analysis. The quotient will be the pounds of deposit per day.

Vanadium-bronze possesses almost perfect resistance to corrosion from salt water and from acid waters. It is 10% lighter than any other bronze made, and has extraordinary tensile strength, ranging from 70,000 to 100,000 lb. per square inch. The so-called vanadium 'silver-metal', a bronze suitable for casting, and extremely resistant to corrosion, has an ultimate strength of 65,400, and an elastic limit of 44,500 lb. per square inch. The only acid against which it is not proof is nitric.

Chrome-nickel steels are usually made in both high and low-carbon types. The former is used for oil-hardened gears and springs, and the latter for general structural purposes, such as axles, shafts, forged parts, and for case-hardened gears in automobiles. The high-carbon type contains about 0.5% carbon, and the low-carbon type 0.25. The nickel varies from 2 to 3.5%, and the chromium from 1 to 1.5. These steels present difficulties in heat-treatment, forging, and machining.

Filtration of concentrate, after grinding and agitation with cyanide solution, was practised many years ago at the Black Oak mine, Tuolumne county, California, by Dan Balch. He used so-called vacuum-pans for this purpose. At that time the sand and slime were fed separately into collecting vats with filter-bottoms. The sand, after draining, was agitated and elevated to leaching vats. The slime was similarly treated, but with the aid of a slight vacuum under the filter. The clear solution, after settling, was also decanted.

Molybdenum deposits are by no means rare, and the mineral molybdenite is found quite abundantly associated with other sulphides in veins of copper and other metals. It also occurs in quite large deposits in Maine. Molybdenite is difficult to concentrate, and only that which can be hand-sorted to a suitable grade of purity could be economically produced. Commercial molybdenite ore or concentrate should contain not less than 92% molybdenum sulphide. The price ranges from 20 to 30 cents per pound for such material.

Case-hardening is a rapid process of cementation in which the surface of wrought iron is converted into steel by heating the article to be treated in an iron box in contact with some organic matter, which will yield up its carbon to the iron. Substances formerly used for this purpose were parings of horses' hoofs, leather, and the like. The operation was performed on a blacksmith's forge. Case-hardening is now done with a chemically definite material, such as a mixture of 60 parts charcoal and 40 of barium carbonate, at a temperature between 850 and 1050°C. After the operation the piece is allowed to cool just below the transformation point, namely, 600°. Reheating it and quenching at 900°C. then has the effect of rendering the centre fibrous.

Special Correspondence.

KALGOORLIE, WESTERN AUSTRALIA.

Taxes.—Ore Stealing. — Phthisis in Mines. — Tanami Explorations.—Phosphate Works at Fremantle.—Mergers.—Output and Dividends.

Some time ago the Western Australian Government demanded extra payment on the dividends paid by mining companies, they being in the habit of paying the dividends after the tax had been paid. This system, the Government declared, was wrong, since the dividend was paid minus the tax. The test case against the Golden Horseshoe was decided in favor of the Government, and the company has to pay $21,000 tax and arrears. The total payable by all the companies will amount to $150,000. There have been several cases of illicit gold dealing of late, the latest device being the use of saloon keepers to dispose of the gold ore through the banks. There have been several convictions. The Government has decided to appoint a commission to enquire into the prevalence of phthisis among the miners. There is little doubt that in the dry and dusty mines of Kalgoorlie there must be many cases of this disease. The commission will also enquire into the nature of the air and gases in the mines, especially after firing shots. The Government analyst is busy taking samples.

The prospecting expedition which left Coolgardie about four months ago well equipped with a camel pack-train to examine the new field at Tanami near the northern border of Western Australia, and the northern territory of South Australia, has returned. The party covered 300 square miles in prospecting, and found little firewood; no water is obtainable by sinking; the country is mostly underlain by sandstone and basalt; wages are $25 per week with food; and freight is $200 per ton from Wyndham, the extreme northern port of Western Australia. In view of the increase in land settlement, and consequent increase in wheat production in the coastal districts, the Mt. Lyell company, of Tasmania, is erecting a plant for the manufacture of superphosphates at Fremantle. It is to cost $250,000. For the manufacture of sulphuric acid, the low-grade copper pyrite with 45% sulphur content, will be used. The phosphate rock will most probably be brought from Ocean Island in the Pacific, or some islands nearer the Western Australian coast.

The latest among the many mergers which have been proposed is that of the Lake View Consols and Hannan's Star Consolidated. The former mine has some 175,000 tons of ore worth $7 per ton, with a 75-head mill using concentration, fine grinding in tube-mills, bromo-cyaniding, and filter-pressing; while the latter mine has about 160,000 tons of $7 ore, but requires a new mill. To save about $250,000 and much waiting on the part of shareholders, it is proposed to join forces, and crush right away. The mines, about one-half mile apart, would most likely be connected by an aerial tramway. In December the gold output from the State was valued at $2,800,000, making the final total for 1909 $33,850,000. Dividends totaled $6,400,000. The chief producers in December were as follows:

Name.	Tonnage.	Yield.	Profit.	Dividend.
Associated	11,481	$76,000	$2,300	.....
Associated North'n Blocks.	3,550	24,500	6,400	.....
Chaffers	4,294	34,000	4,400	.....
Golden Horseshoe	25,458	240,000	92,000	.....
Golden Ridge	2,167	28,000	14,000	$32,000
Gt. Boulder Proprietary	18,244	250,000	136,000	328,000

TONOPAH, NEVADA.

Tonopah Extension. — Montana-Tonopah. —McNamara.— Tonopah Mining Co.—Belmont.—Tonopah Midway.

The Tonopah Extension Mining Co. is mining and milling 110 tons per day of ore that assays $14 per ton, the proportion of the metals being 90 oz. silver to 1 oz. gold. The mine levels are at the depths of 270, 400, 500, 600, 770, and 1050 ft. The bulk of the ore that is being hoisted comes from all levels down to and including the 600. Within a few weeks the 700-ft. level will begin producing. The shaft was sunk 180 ft. through the cap-rock, then into the earlier andesite, cutting the vein at 220 ft. The orebody has an east-west strike, and a dip of 40° north. The hanging wall is well defined, and the foot-wall not, the width of ore stoped ranging from 4 to 30 ft. The gangue material consists of quartz and silicified andesite. The vein is opened a distance of 200 ft. east of the shaft, extending to the property end-lines; and 1000 ft. west from the shaft, with driving westward still in progress. Plans are made to cross-cut from the principal orebody to intersect and open two other veins which strike parallel to the main one. These two subsidiary veins are believed to contain ore of commercial value. The new mill, which has been in operation a little over a month, is doing satisfactory work, making an extraction of 90% of the gold and silver—35 by concentration and 55 by cyanidation.

The Montana-Tonopah is taking its principal tonnage of

Montana-Tonopah Mill.

ore from the Triangle and Martha veins, and mostly out of levels from the 396 to the 765 inclusive. The ore hoisted and milled amounts to 130 to 140 tons per 24 hours. An average extraction of 91% is made—37 by concentration and 54 by cyanidation. A coarse clean concentrate of 35 tons per month is made on Wilfley tables, and 65 tons of fine per month on the vannera. The coarse product contains 800 oz. silver and 5 oz. gold per ton, while the vanner product averages 220 oz. silver and 1¾ oz. gold per ton. The coarse concentrate contains usually 16% iron, 51 silica, 10 sulphur, 5 alumina; the vanner concentrate contains about 9% iron, 4 sulphur, 3 manganese dioxide, 2½ alumina, and 78 silica. In connection with the cyanide work the mill tailing is re-ground in tube-mills, subjected to cyanidation with agitation and aeration. The slime, 75 to 80% of which will pass 200 mesh, is put through Butters filters. The consumption of cyanide is 2 lb. per ton of ore milled, that of lime 9 lb., and zinc dust 1¼ lb. The precipitate is cleaned up in Merrill presses, then fluxed and melted in Butters tilting furnaces, for which crude oil is used as fuel; in each melt there are 1½ tons of precipitate, there being two melts per month. The bullion runs 875 to 900 fine, and is shipped without refining to the Selby Smelting & Lead Co., at San Francisco. Edgar A. Collins, the company's manager, states that the cost of mining is about $3.44 per ton of ore, that of milling $3.76. The development for 1909 cost $1.71 per ton of ore mined. The value of the ore is about $15 per ton. The power for all purposes is figured nominally at $8 per horse-power month, but it actually runs

up to $2 to $3 higher than this. The air-compressor, having the capacity of 1300 cu. ft. of free air per minute, is electrically driven, and this supplies air to run the mine-hoist and air-drills. The company, however, has a battery of three steam boilers and a steam-hoist in reserve. The mill work is under the superintendency of B. A. Bosqui.

The McNamara mine, under the superintendency of J. W. Chandler, is producing a carload of ore per day which is shipped to the Balaklala smelter at Coram, California, where highly silicious ore is in demand. This ore contains approximately 81.7% silica, 2.4 iron, 0.9 lime, and 5.3 alumina, and carries 1 oz. gold to 90 oz. silver. The value of the ore runs from $20 to $30 per ton. This production comes from the levels above and including the 375-ft. level. For 1909 the gross production of the mine was $359,579, the mining costs having been $4.58 per dry ton of ore marketed. During that year there were mined 16,229 tons of ore having an average gross value of $22.15 per ton.

The Tonopah Mining Co. is mining and milling 460 tons of ore every 24 hours, the grade averaging $21 per ton. Like most of the ore in this district the proportion of gold to silver, in ounces, is about 1 to 90. The ore contains about 85% silica and runs low in iron. The gold is mostly free, while the silver occurs as sulphide, chloride, bromide, and iodide. The principal veins are the Mizpah, having a dip of 60° north; the Silver Top, a vertical vein, and the Valley View, having a 45° dip north. The Mizpah shaft is 1500 ft. deep, though none of the present ore-producing levels are below the 700-ft., and the only development in progress below the 700 consists of diamond-drill exploration work on the 1500-ft. level. The Silver Top shaft, which is 740 ft. deep, serves as an ore-hoisting shaft for both the Silver Top and Valley View workings. The width of ore encountered in the three veins ranges from 1 ft. to 40 ft. The hoisting machinery consists of three flat-rope Wellman-Seaver-Morgan electric hoists. There are three air-compressors, one each of Ingersoll-Sergeant, Fulton, and Laidlaw-Dunn-Gordon, the last having a Rix automatic unloader for regulating the amount of air by holding open the intake valves till compression is needed. The company is sinking a 5 by 9½-ft. shaft just west from the railroad depot, on its Sand Grass claim. It is now down 160 ft. and may be sunk 500 to 600 ft. All work on this company's property is done under four department heads—W. H. Blackburn, mine superintendent; A. R. Parsons, mill superintendent; W. W. Charles, comptroller; J. T. Wolfe, of the power department. Each of these department superintendents reports direct to J. S. Austin, president of the company, at Philadelphia. A system of dividing up shifts in the mine has been inaugurated here which is claimed to work satisfactorily; the day shift goes on at 7 a. m., and goes off at 3:30 p. m.; the next shift works from 3:30 p. m. till midnight; the blasting crew of five men goes on at 9:30 p. m., firing the holes of both day and night drill crews, performing the work in such time as to give 7½ hours ventilation on levels, instead of 3½ hours where shifts are separated. This plan has been in vogue for a year. Development progresses at the rate of about 500 ft. per week, and the timbering costs 40c. per ton of ore mined. The mine force is 180 men, of which 90 are on the surface, including hoisting engineers, compressor men, machinists, assayers, surveyors, and electricians. Among other men on the mine staff, not mentioned elsewhere, are J. A. Burgess, engineer and geologist; J. M. Fox, assistant to Mr. Blackburn; J. D. Murphy, general mine foreman.

The Belmont mine is operated by the Tonopah-Belmont Development Co., with F. Bradshaw manager and R. J. King as mining engineer. This company no longer operates its mill at Millers, but ships its output of 100 tons of ore per day to the United States smelting plant at Kennett. The ore runs over $30 per ton, the proportion of gold and silver being the same as in other ores of the district. Their Desert Queen shaft is 1100 ft. deep, levels from which open the four veins of the property. The new Belmont shaft, which is 1000 ft. deep, is 1800 ft. east of the Desert Queen, and the design is that it shall become the main working shaft. A new body of ore was found in the vicinity of this shaft. It was opened by a blind level that was driven from a winze which was sunk from the 1000-ft. level of the old shaft. This blind level was then connected with the new shaft. The orebody is on the hanging wall of the Mizpah fault. The new shaft will be enlarged to 3 compartments, and further sinking will be started from the 1000-ft. station. The Occidental veins were opened by levels from the old workings at 800, 900, and 1000-ft. depth. The Occidental series is the same as the Valley View of the Tonopah M. Co. Before shipping the Belmont ore it is passed dry through a revolving screen, having 1-in. openings, thence through a revolving spiral ore-washer, Crane type, discharging upon a sorting belt, from which the fragments of barren porphyry are thrown out.

The Tonopah-Midway Mining Co., for 1909, shipped 4546 tons of ore, the gross value per ton being $38.59. The development for the year aggregated 6346 lineal feet, measuring raises, winzes, cross-cuts, and drifts. Those who are active in the management of the company's affairs comprise H. C. Brougher, W. J. Douglass, T. L. Oddie, N. Nelson, J. J. McQuillan, R. P. Stenson, H. Anderson, and E. J. Erickson.

JOHANNESBURG, TRANSVAAL.

Mineral Production. — The Outside Districts. — Base Metals. — Cape Colony Gold —Some Troubled Mines.—Esperanza and Rand Mine Sampling.

The Government Mines Department has issued its usual comprehensive report for the fiscal year to June 30, 1909, and, although behind the times, it may be made to provide some figures here in illustration of recent progress and the magnitude of mining operations in general. First in importance comes the mineral output; the main classes of product, compared in value for the years to June 30, 1908 and 1909, are as follows:

	1907-8.	1908-9.
Gold	£28,508,368	£30,986,965
Silver	90,175	87,457
Coal	778,669	851,150
Diamonds	1,879,551	1,295,296
Copper	32,400	49,027
Tin	81,677	148,336
Lead	21,761	25,432
Magnesite	900	1,487
Asbestos	11,802	7,400
Zinc	5,837	4,043
Flint	12,350	23,776
Graphite	20	78
Mercury	5	.....
Mica	.....	200
Stone, brick, pottery, etc.	153,615	173,555
Chemicals	4,834	24,300
Lime	52,474	61,955
	£31,634,128	£33,739,458

There is an increase under twelve heads. The silver yield is almost wholly represented by that obtained from Rand bullion. A visiting engineer remarked at a recent technical meeting that it was not generally recognized that the output of base metals in the Transvaal already equalled that of gold from districts outside the Rand. This statement was anything but true—for the outside gold yield averages £1,000,000 per annum—but the above figures clearly show that fair progress is being made. The value of the report is greatly enhanced by a general review of progress in the lesser mining districts by U. P. Swinburne, Inspector of Mines. The gold districts discussed are the following: (1) Barberton, in which two cases of disappointment had to be recorded in the failure of gold-dredging and in the lapse of the once famous Sheba into the tributing stage; (2) Lydenburg, which has been exceptionally active and of increasing prosperity; (3) Pietersburg, where a closing down of work has been the rule; and (4) Leydsdorp, where the proposed new railway has led to the acquisition of more ground for prospecting purposes. The principal base metals noted are tin, copper, and lead. The bulk of the tin yield still comes from Zadiplaats and Groenfontein, on which the two 'pipes' of rich ore are said to show no sign of de-

preciation. The colony's copper is drawn almost excessively from the Messina mine, where the outlook is bright and where the large untouched area of ancient workings should further contribute to the output. The Inspector of Mines declares that the whole Messina area is well worth prospecting and that probably other mines will be located when the transport and working facilities have been improved by the construction of some northern railway. As for lead, the Transvaal has been showing little progress. The country's galena deposits are unfortunately poor in silver, and the lead alone is insufficient to give the small deposits much chance of commercial success. The Edendale silver-lead mine in the Pretoria district continues working on a small scale. The only other products mentioned in the report are molybdenum, deposits of which have been found, though without commercial value at present, and mica, which is being mined at Malalane, in the eastern Transvaal. Since the end of the fiscal year the Macoutsie River Valley Syndicate is reported to have been producing some mica of good quality. Too hopeful a view cannot be taken when the infinitely better favored mica mines of Bengal and Madras are finding difficulty in disposing of their high-grade product at standard prices.

Judging by reports coming to hand from Cape Town, a determined effort is being made to revive interest in the Millwood or Knysna district, where certain conglomerates of the Table mountain series (bearing a resemblance to Rand banket) have been from time to time tested and found poorly auriferous. A company named the Cape Gold-Fields (Proprietary), Ltd., is being formed with a capital of £200,000 and a directorate of Cape Colonial magnates, whose experience of treasury deficits should enable them to face gold shortages and working losses with serviceable equanimity. The description of the property and extracts from the consulting engineers' report should be enough to condemn the property in the eyes of experienced mining investors, and those who are 'out for a gamble' would like to see smaller capital proposed. In looking into the prospects of the concern, one does not want historical explanations of failure nor elaborate descriptions of 'working facilities', but simply an intelligent summary of sampling results. These, it may almost be said 'of course', are not to be found in the columns of reading matter comprising the abridged prospectus. It is stated that "the company's engineer has defined 12 interbedded parallel reefs, and the average value is declared in the following words, 'I can with confidence describe the whole property to be an enormous highly mineralized field which will average 9 dwt. over a 3-ft. milling width.'" There is also a jumbled statement of 'composite samples', with results of doubtful significance. The promoters, with the common tendency of their profession, lay particular stress upon the perfect reliability of the assayers employed, including the Cape Government Laboratory, The Standard Bank, and Messrs. Johnson, Matthey & Co., of London, unmindful of the fact that for every ½% error in assaying there is probably a 100% error in the sampling, and that if an inefficient assayer poured away 9 dwt. in a 10-dwt. charge, he would often only be allowing a balance of personal errors to create a chance accuracy. At all events, in the present case, he would have helped unconsciously to remove the erroneous impression that Millwood is a "highly mineralized field averaging 9 dwt. over a 3-ft. milling width."

The labor position is improving satisfactorily, but the demands are so great and increasing that it is not yet time for thanksgiving. On the strength of the improved position the Geduld is starting, and many mines will receive recruits in time to save them from serious difficulties. While there are many bright spots along the Rand, it must be admitted there are several points of weakness. The closing down of the French Rand some time ago turns one's thoughts to the stability of other mines in the district. The Champ d'Or has now almost exhausted its ground and will be closing down in a few months. The Luipaardsvlei Estate is undoubtedly doing badly with its profit down to £200 in December. As a mine that has often been held up to the world as a model of technical skill, its fall appears the more serious. Dividends were paid in 1908 and 1909. Another mine—in more serious difficulties—is the Vogel Deep, where crushings are said not to have come up to expectations. Such a condition, if true, involves mystery, for the thoroughness of Rand sampling should leave no room for a discrepancy of more than 20%. The Simmer Deep has been doing wonders in the way of costs (12s. 6d., including development), but the fall in yield tells its tale (17s.). A large quantity of 'ore' is drawn from dump accumulations.

In an article on the Esperanza mine in the MINING AND SCIENTIFIC PRESS of December 25, W. E. Hindry gives some notes on sampling systems that appeal especially to the Rand engineers, for the Johannesburg mines are subjected to such thorough routine sampling. Mr. Hindry writes: "In case there was a doubt as to whether the portion of the stope where this occurred (erratic distribution of gold and silver) was above or below the payable limit, the broken ore was left in the stope until the pile could be thoroughly sampled." The care displayed in leaving underground rock upon which losses would be incurred in hoisting and treating serves as a good object lesson to some Rand managers, who, driven by the call of excessive plant and the clamor for low costs, put through the mill a great deal too much unpayable rock. When the stope sampling shows an unpayable face, it will usually be given another month's run, unless the development results preclude the possibility of a return to payability. But it would be something quite remarkable for managements to leave the ore already broken, on account of poor face-sampling. The reason is that the margin of payability on rock already broken is extremely low, owing to the comparatively small cost of subsequent operations. In the first place, it is probable nowadays that the plant is not being run at maximum capacity and that the extra cost for treating this broken rock would not be equivalent to the average costs per ton. Standing charges would be inappreciably increased under these conditions, and in any big mine, ore already broken may be ranked as payable if calculated to yield 6s. or 7s. per ton. This would mean, with 15% sorting and 95% extraction a payable mine grade of only 1.5 dwt., which shows that any precautions such as those taken at the Esperanza would not be justified upon the Rand, where a sudden fall in stope grade to this value (discovered after the rock is broken), would be a most remarkable experience.

NEW YORK.

Porcupine Scenery for Sale.— Bureau of Mines. — Phelps-Dodge Record.—Kerr Lake.—Mason Valley.—Guanajuato Amalgamated.

New York is receiving the vanguard of the Porcupine prospectors. The district itself is still covered with a three-foot blanket of snow, but some of the hardy pioneers of the Canadian camps have been shoveling and sweeping off ledges and with sacks and satchels of 'picture rock' fairly laden with leaf gold, have descended upon New York with vast areas of the untrodden wilderness for sale. Asking prices run into the tens of thousands for ground that is only claimed to show quartz outcrops. Samples said to have come from the bottom of the 60-ft. hole on the Timmins property, formerly known as the Hollinger group, show enough gold to run into fabulous values. None, save the long shot gambler, who delights in desperate chances, considers the purchase of Porcupine claims seriously, but the fact remains that none of the engineers who have examined the ground and the surface showings feels that the discovery should be turned down. Geological conditions are reported to be such as to warrant a request for suspension of judgment.

The bill to establish in the Department of the Interior a Bureau of Mines, has been reported out by the Senate Committee on Mines and Mining with favorable recommendation. The scope of the bill, or rather the work which it is intended the Bureau shall take up, is outlined in the committee's report. None who has the good of the mining industry at heart, will object to the broad lines laid down to be followed by the proposed Bureau of Mines. If through its efforts progress in the science of metallurgy can be gained, and relief from the much complained of exactions of the smelters be afforded to the individual and small operating companies, it will be cause for great rejoicing.

There is another element, however, that enters into the making of the condition described in the committee's report. A mines' act that will compel a rigidly true statement of financial conditions in the prospectus of every mining company, that will forbid the use of the advertising columns of the press for flamboyant, misleading, and untruthful advertising of mining companies, and that will forbid the use of the mails to the promoter who is seeking to mulct would-be investors, that will enforce the making of monthly or quarterly reports, both as to financial and physical conditions, and will insist upon such reports being made intelligible to the lay mind, is equally needed.

Declaration of the recent quarterly dividend by the Phelps-Dodge company, has attracted some attention to this concern's record. Since the incorporation of Phelps, Dodge & Co., in 1908, there has been returned to the stockholders $7,250,000, equal to 14½% on the company's capital of $50,000,000. If this rate is maintained for seven years the company will have returned to the shareholders the entire capital stock. The estimated production for 1909 of the Copper Queen mine is 134,000,000 lb. copper, making this mine the largest single producer in the country. In 1909 the company paid $6,000,000 in dividends. While it is not likely that production for the current year will surpass last year's figures, any material improvement in the copper market will permit of a considerably better showing.

It is believed here that there will be some important consolidations at Cobalt in the near future. The Kerr Lake and the Crown Reserve, two of the most important dividend payers of the camp, are said to be negotiating for a merger. The Mason Valley Mines Co., operating at Yerington, Nevada, has reorganized with an increase of capital stock from $1,000,000 to $2,500,000; an issue of $1,000,000 of 6% ten-year first mortgage gold bonds has been authorized. The bonds are issued in denominations of $500 each, convertible at par. The control of the Guanajuato Amalgamated has been sold to the Securities Corporation, Ltd. The figure realized for the interest transferred has not been made public. The Guanajuato Amalgamated's mill is one of the most complete in the camp, but it has never been a success in the hands of its former owners.

MEXICO.

Railroad Development. — Calumet & Sonora. — Lead-Zinc. — Pedrazzini.—Tigre, Sonora.—New Cananea Reverberatory.— Amajac, Jalisco.—Amparo.

The present year promises to be notable for railroad building that will benefit the mining districts of the Republic. Construction is in progress in many places, and a number of important lines are planned. The Southern Pacific is opening the rich Yaqui river region by the construction of its Yaqui river extension, and the main line is being built south through the Territory of Tepic, the construction forces being between the Santiago river and the City of Tepic. South of the Tepic capital the line will open the old Compostela district, famous for its heavy production during the colonial days. In the State of Oaxaca the Mexican Southern railway, now controlled by the National Railways of Mexico, is completing a branch to the Taviche district, and will proceed immediately with the construction of a branch to the Magdalena district. Richard Honey, a Mexico City banker, heavily interested in the State of Hidalgo, is building a railroad from Pachuca to Zimapán, in that State, and great activity is expected at Zimapán in consequence. Much mineral ground has been denounced there within the last few months. The Mexico Northwestern Railway Co., headed by F. S. Pearson, is closing the gap between Terrazas and Madera, in the State of Chihuahua, by the construction of 110 miles of road, and the line will place transportation facilities much nearer the old Guaynopa and Guaynopita mining districts, where many properties are under title. A branch of the Chihuahua & Pacific to Cusihuiriachic, a distance of 13 miles, is proposed by the Pearson company. Work has been started by the National Railways on 100 kilometres of railroad west from Durango to Llano Grande, and the line will be of benefit to some Durango mining sections. The Mexican Pacific Co., composed of Seattle and Victoria capitalists, is building a line to connect the Pacific ports of Acapulco and Zihuatanejo, in the State of Guerrero, and mining districts in the mountains back from the coast are interested. A railroad from Teziutlán to the Gulf port of Nautla, now being financed, will give the Teziutlán Copper Co. a direct outlet for its smelter products. The Coahuila, Chihuahua & Northwestern Railway Co., backed by Mexican City bankers, will build from Monclova, in the State of Coahuila, to the Chihuahua capital, through a territory now distant from transportation facilities. Silver-lead and zinc mines, coal-fields, iron deposits, salt lakes, and kaolin deposits will be tributary to the line. Charles Deering, of the International Harvester Co., is at the head of a syndicate that is financing the Cienegulta & Sonora Central Railway Co., organized to build across the Sahuaripa district of Sonora from Tonichi, on the Yaqui river extension of the Southern Pacific, to Yecorra. The Franco-British Syndicate has been organized by French and English interests to build from La Vega, on the National Railways, west through the State of Jalisco to the Pacific port of Chamela. The line will open the Ayutla, Bautista, Parnaso, Autlán, and Purificación mining sections. It is stated that English interests will extend the Torres & Prietas railway through the Barranca district of Sonora to a connection with the Yaqua river line of the Southern Pacific.

The property of the Calumet & Sonora Co., in the Cananea district of Sonora, is now ranked as one of the greatest lead-zinc mines on the continent. The ores run from 60 to 85%, and the development so far has placed a big tonnage in sight, and gives promise of great additional supplies. An incline shaft is down 400 ft. A mill of the Joplin type is handling about 100 tons daily and is giving satisfactory results. Regular shipments are made to Swansea, Wales. Due to the development of a large tonnage of milling ore, the Pedrazzini Gold & Silver Mining Co., operating important gold-silver mines in the Arizpe district of Sonora, has purchased additional equipment for its reduction plant, and expects to mill 50% more ore in future. The company is a steady shipper of high-grade ore, and is paying substantial dividends. The Noche Buena Sonora Mining Co., owning mines in the Yaqui river region, 25 miles from Tonichi, has purchased equipment for a small reduction plant, and will erect it immediatley. The company also owns placers on the Yaqui river, and plans to install equipment to handle 500 cu. yd. of gravel per day. D. L. H. Forbes, who had charge of the construction of the new 700-ton cyanide plant of the Esperanza Mining Co. at El Oro, is building the cyanide plant at the Tigre mine of the Lucky Tiger Gold Mining Co. There is a big accumulation of tailing that will be cyanided as soon as the plant is ready. The Tigre continues to develop exceptionally, and much rich ore is being shipped. A second reverberatory furnace, an exact duplicate of the one now in operation, is being erected by the Greene-Cananea Copper Company.

Deliveries of machinery for remodeling and modernizing the Amajac reduction works in the Hostotipaquillo district of Jalisco will be made within a few weeks. The reduction works are now the property of the Amajac Mines Co., which acquired them in connection with the Refugia, Animas, and Tres Estrellas mines. W. R. Ramsdell, a well known Jalisco operator, is at the head of the enterprise. The plant will handle 75 tons per day, and custom work will be done. The Amparo Mining Co., operating in the Etzatlán district of Jalisco, produced ₱122,557 in January and ₱121,759 in February. The company is paying dividends of 1% per month on $2,000,000.

The Oro Grande Mines Co., organized last year with a capital of $9,750,000 to re-open and work the famous old producers of the La Luz camp of Guanajuato, has placed orders for compressor plants and electric hoists preparatory to commencing operation. The compressors and hoists are to be installed within 90 days. The company has been placing stock since its organization. According to published weekly statements the ores, concentrates, and bullion shipped out of the Guanajuato district in February had a value of ₱1,055,000. Shipments in the first week of March reached a value of ₱275,000, the highest so far this year.

BUTTE, MONTANA.

Smoke Litigation.—Butte-Ballaklava Installs New Electric Hoist.—Butte-Alex Scott Vein.—Butte & Superior.—Corbin Mines.

While business conditions have been disturbed again by the report that proceedings have been instituted to secure an injunction looking to the closing down of the Amalgamated company smelter at Anaconda, there is a feeling in this city that no such action will be taken. The Amalgamated company claims that everything possible to do away with the smoke nuisance, so called, has been done at an enormous outlay, but that no practical system by which the smoke's elements can be disposed of has yet been discovered. It is also claimed that the statements regarding the damage by the smelter's operation are greatly exaggerated. The new electric hoist for the Butte-Ballaklava Copper Co., which arrived several days ago, is in position and in working order. The hoist is the first deep-sinking electric hoist to be erected in this district and takes the place of the electric hoist which has been in operation at the Butte-Ballaklava for the past year. It will be driven by a 350-hp. General Electric motor. It has a capacity for sinking to a depth of 3000 ft., is provided with air-brakes and clutches, and is one of the most complete. The Butte-Ballaklava expects to increase its output to 4500 tons per day. A new head-frame has been constructed, carrying two sheave wheels each 6 ft. diam. New steel ore-bins capable of holding 700 tons of ore have also been built. The new hoist was built by the Lake Shore Machinery Co., at Marquette, Michigan. The Butte-Alex Scott is considering constructing a concentrator. The principal work in the mine during the past few months has been on the 1400-ft. level. The vein, which is more than 40 ft. wide on this level, was intersected within a short distance of the shaft, and a drift about 100 ft. west opened an orebody about 18 ft. wide. Much of the ore is said to be of exceptionally high grade. The orebody has been proved on the 1200, 1000, and 800-ft. levels. The Butte & Superior during February shipped 6000 tons of ore to the concentrator at Basin that netted $3.75 per ton after paying mining, transportation, and milling charges. An auxiliary hoist is to be installed, and this will increase the tonnage to 450 tons per day, and at the same time decrease the cost of mining. The Boston and Alta new shaft is now down 605 ft., or some 42 ft. below the deepest workings of the old mine. At the 660-ft. level a cross-cut will be driven to the Alta and other veins. Several stringers of ore have been cut in the shaft. These vary from 1 in. to 1 ft. in width and carry from 3 to 4% copper, together with small amounts of gold and silver. A new electric air-compressor has been put in with a hoist capable of sinking to 1500 ft. Representatives of the H. L. Frank estate, owning a controlling interest in the Southern Cross mine, situated a short distance from Anaconda, positively state that the report that the United States S. R. & M. Co. has purchased the mine is untrue. At a depth of 250 ft. in the east drift at the Montana-Corbin mine the vein has widened to 2 ft., assaying 6% copper and 19 to 20 oz. silver. The dip is toward the shaft, and on the 400-ft. level this vein was intersected in cutting the station. On the latter depth the vein is 62 ft. wide between the walls, and contains numerous generous streaks of high-grade ore. The walls are well defined and identical with the Butte granite. In every way the formation is the same as that in the Butte district, the only difference being that valuable ore is found nearer the surface. Shipments will begin in a few weeks. The stock of the Corbin Metal Co. is to make its appearance on the New York curb in a short time. The property consists of 178 acres of ground.

At a special meeting of the stockholders of the Anaconda Copper Mining Co., March 23, it was decided to increase the capitalization of the company, and to offer to the following named companies the respective amounts herewith of the capital stock of the Anaconda Mining Co. in exchange for the properties owned by them: to the Boston & Montana, 1,200,000 shares; Red Metal, 500,000; Washoe Copper Co., 380,000; Butte & Boston, 300,000; Big Blackfoot Lumber Co., 300,000; Trenton, 120,000; Diamond Coal & Coke Co., 100,000; Parrott, 90,000; and Alice, 30,000 shares.

WASHINGTON.

Bureau of Mines. — Alaska Legislation and Railways. — Coal Reserve.—Naval Oil Reserve in Oklahama.—Land Surveys.

The Bureau of Mines bill, which passed the House more than a month ago, has been reported favorably to the Senate by the Committee on Mines and Mining. Before this action was taken, the committee listened to arguments in favor of such a Bureau from D. W. Brunton, of Denver, Colorado, president of the American Institute of Mining Engineers; E. R. Buckley, Rolla, Missouri, president of the American Mining Congress; H. D. Mannington, Columbus, Ohio, secretary of the Coal Operators' Association of Ohio; Samuel A. Taylor, of Pittsburg, Pennsylvania, secretary of the Pittsburg Coal Operators' Association; W. D. Blair, secretary of the National Brick Paving Manufacturers' Association; and J. F. Calbreath, Jr., of Denver, Colorado, secretary of the American Mining Congress. As reported to the Senate the bill provides for a Director at $6000 a year instead of a Commissioner at $5000, and this adds that the Director shall be thoroughly equipped for the duties of his office by technical education and experience. Members of the committee insisted that the Bureau should be a scientific organization with a scientific man at its head, and that the place was not one for a politician. That phrase in the House bill which declares it to be the province and duty of the Bureau "to foster, promote, and develop the mining industries of the United States" was stricken out in order to keep the Bureau out of any phase of the work other than that of scientific investigation, although practically every bureau of the Government has a similar statement of purpose in its organic act. Section 5, which is an amendment, is as follows: "That nothing in this act shall be construed as in any way granting to any officer or employee of the Bureau of Mines any right or authority in connection with the inspection or supervision of mines or metallurgical plants in any State or Territory."

Alaska and her minerals still occupy a considerable share of public attention in Washington. The bill, which was introduced in the Senate several weeks ago by Albert J. Beveridge, of Indiana, creating a Legislative Council and conferring legislative powers upon the district, is not to be pressed to passage at this session. Considerable opposition arose and the bill was liberally amended. Then it was decided, in view of the chaotic conditions in regard to the mineral lands, to hold the matter over. That Alaska will continue to develop in the meantime is evidenced by the number of bills being introduced affecting the district. Henry W. Palmer, representative from Wilkesbarre, Pennsylvania, in behalf of Eastern capitalists, most of them from Philadelphia, has introduced a bill giving Government aid in the construction of a railroad, telegraph, and telephone line in Alaska. The line is to be known as the Alaska Great Northern railroad, and will begin at a point on the Gulf of Alaska, at or near the head of Valdez bay. James Wickersham, delegate from Alaska to Congress, has introduced a bill to extend the time for beginning construction of the Alaska Short Line railroad. Reed Smoot, Senator from Utah, has a bill which seeks to relieve the Copper River & Northwestern Railway Co. from license tax and tax on its property during the period of construction and for five years thereafter. A bill to create a national coal reserve in Alaska has been introduced in the Senate by George C. Perkins, of California. The bill provides for the reservation of 5000 acres of the best coal lands in the Katalla district, 5000 acres in the Matanuska district, 5000 acres in the Kenai peninsula, and 5000 acres in the Alaska peninsula. This bill was followed by another by Thomas P. Gore, Senator from Oklahoma, seeking the creation of a reserve fuel oil supply for the United States Navy. The bill authorizes the Secretary to acquire such land as is necessary adjacent to the oilfields of Oklahoma for the erection of tankage and the laying and gathering of such lines as will be necessary to purchase directly from the producers of oil, at a price as low as the market conditions and the demands of the Navy shall justify. One million dollars is asked by Richard A. Ballinger for public land surveys for the coming fiscal year.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Copper Queen company has been experimenting with 'Missouri' candles and Leyner drills.——The drift from the Holbrook shaft on the 200-ft. level to the Uncle Sam has been put into condition, the trolley wire is up, and a motor is now hauling all the ore from those two places.——At the Czar, on the 500-ft. level, a diamond-drill at a depth of 250 ft. entered a deposit of soft sulphide.——On the 1400-ft. level at the Lowell a drift runs for 800 ft. through a good sulphide ore, and a winze sunk on this level shows it is over 100 ft. deep. The Lowell shaft will have to be sunk to the 1600-ft. level in order to get under the orebody. On the 800-ft. level samplers discovered an orebody of high-grade oxide; of 35 samples taken the last one assayed 28%. ——The Sacramento shaft is now 1680 ft. deep. A drift is being run on the 1600-ft. level to get under the great ore-body of the Lowell.

GILA COUNTY.

(Special Correspondence).—Work has been resumed in the No. 4 shaft of the Miami Copper Co. from the depth of 600 ft., where a temporary delay was due to lack of creosoted shaft timbers. On the 420-ft. level of the mine, tracks and switches are being laid for the motor cars. The ore-body above this level is practically ready for extraction by the 'caving and auxiliary raise' method. It is estimated that about 3000 tons can be extracted daily through the 420-ft. level. The steel frame for the machine shop is erected and work is begun for the concentrator building adjoining. The machinery for the power-house and machine-shop is expected soon.——The last two churn-drill holes put down on the Inspiration property, about 800 ft. south of the Scorpion shaft and 1600 ft. west of the Joe Bush shaft, passed through about 300 ft. of ore. The cross-cutting south on the 275-ft. level of the Scorpion shaft continues in ore 380 ft. from the shaft. Raising is the principal work in progress at the Joe Bush 400-ft. level. A new wooden head-frame at this shaft has been put in commission, and cages are now being installed. The 15-drill compressor in Keystone gulch is being given its first trial. It will operate four or five air-drills in the Joe Bush workings and two in the Keystone Gulch adit.——At a depth of 640 ft. a 4-in. seam of specular hematite, accompanied by some copper stain, has been encountered in the Williams shaft of the National Mining Exploration Co.——The Boston-Miami Copper Co., just incorporated, has taken over the property of the Boston-Miami Development Co., and the following officers were elected: H. F. Fay, president; C. J. Morrissey, secretary and treasurer. In addition to these two officers, the board of directors consists of George G. Endicott, Walter L. Frost, and James Gardner. Alton B. Dickerman is consulting engineer; F. W. Hoar is superintendent. About forty men are employed in churn-drill operations.——The churn-drill operations on the Schultze group of claims, in the southwestern part of the Miami district, have been discontinued.

Globe, March 19.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence).—It is rumored that the Empire Mines Co. has made an offer for the Pennsylvania group. The latter is one of the best known properties in the district and has been a steady producer for a number of years. ——The main adit at the Fruitvale has opened 8 ft. of milling ore at a point 450 ft. from the portal. It is intended to install a compressor and machine-drills in the spring. Andrew Fitzgerald is manager. San Francisco and Oakland capitalists are interested.——The vein in the foot-wall of the 800-ft. level of the Champion has widened to 9 ft. Twenty stamps are dropping on ore from this point and 73 men are on the pay-roll. It is possible that the Home shaft will be sunk 200 ft. deeper to open the new vein in the Champion workings. The vein mills about $6 per ton.——The tunnel being driven on the Constitution vein is expected to intersect the Great Western vein within 100 ft. Adits on the Douglass and Cheyenne claims are being repaired. All of these properties lie in Willow valley and are owned by Peter Tautphaus, of San Francisco. Chinese lessees on the Jerry Goodwin placers, near You Bet, recently cleaned up $20,000 after working a few months.——It is stated that the Birchville mine will shortly resume activities.——A dispatch from New York states that negotiations for the acquisition of the Murchie mine by the United States Smelting, Refining & Mining Co. are under way. E. H. Wilson, former manager of the Sixteen-to-One mine is conducting affairs.——At the Golden State a vein of $13 ore is being developed. It contains a small percentage of copper.—— Wall Bros. are developing a promising auriferous deposit on the Shields ranch. It consists of a 100-ft. porphyry dike, between walls of granite and slate, and was formerly worked by sluicing.

Grass Valley, March 21.

TRINITY COUNTY.

(Special Correspondence).—Chapman Bros. have opened a new gravel channel above Junction City. The first clean-up gave 12 lb. of gold and the indications are that the channel is much more extensive than was expected.——Hennesey & Fulmore are working the Sherwood mine on a lease and have some high-grade ore. Skinner, Fields & Meckel are preparing to resume work on the Mountain Boomer. Options have been begun on several other properties in the Upper New River district. A find was recently made in the Yellow Jacket district on the opposite side of the mountain from the Yellow Jacket mine. The ore is of the same character as that in the Yellow Jacket. The small placer mines are working on full time with prospects of a good season's run.

Weaverville, March 21.

TUOLUMNE COUNTY.

(Special Correspondence).—A small but rich vein has been uncovered by cross-cutting to the hanging wall on the 650-ft. level of the Republican mine.——A large number of placer locations have lately been made in the Jawbone district, through which, it is believed, runs the rich channel that is being worked near Groveland. Coarse gold has been found in several of the claims. Some promising quartz veins are also known, and unusual mining activity is expected this summer.——The mill at the Dutch mine, which was recently partly re-constructed, has been given a trial run and will soon be in continuous operation, crushing ore from the 400, 600, and 800-ft. levels.——The Cleveland mine, situated two miles north of Tuolumne, and owned by J. Sivori and sons, has been bonded to G. E. Brown, of San Francisco.——A 10-stamp mill has been purchased for the Blue Lead group of mines, which are situated near the junction of Moccasin creek and the Tuolumne river, and operated by S. Bjorlen and C. H. Gustafson. The Blue Lead vein averages 5 ft. wide and assays from $5 to $10 per ton.——Work has been resumed in the Grizzly mine with a small force of miners.——Work has also been resumed at the entrance to the main adit of the Providence mine.——The Columbus mine, three miles northwest of Tuolumne, has been bonded.——Barrett Bros., who have driven an adit 150 ft. at their property two miles southeast of Confidence, have found a shoot of ore 6 ft. wide that assays $20 per ton.——Rich ore has been uncovered in the shaft at the old Oliver mine, near Steven's Bar, by Marcus Mullin and George Murphy, who are working the property under lease.——A hoisting engine has been installed at the Bismarck, and sinking is again in progress. The bottom of the shaft is in good milling ore.——The large restraining dam at the Little Gap gravel mine is nearing completion, and it is expected that mining operations will begin within a few days.——A contract has been let to drive the adit at the McCormick-McPherson mine, east of Jacksonville, an additional 100 ft.——Another body of fine ore has been opened in the south drift on the 500-ft. level of the Draper mine. The mill has been running day and night, with good results, but is now temporarily idle owing to the breaking of a cam-shaft. Thirty men are employed.——Operations have been resumed at the Black Oak mine, the new drum for the

hoist having arrived.——Development will be commenced about May 1 at the Ryan mine, near Sugar Pine, recently bonded to J. C. Spangler, of New York.

Tuolumne, March 19.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A body of smelting ore 2 ft. wide was encountered last week on the Charter vein operated through the LaMoe adit.——A 10-drill compressor arrived the first of this week for the Bellevue-Hudson mine, situated on Columbia mountain. In the bottom of the shaft, down to a depth of 120 ft., a body of smelting ore 2 ft. wide has been found that is worth $380 to the ton in silver and lead.——Work has been resumed in the raise from the Scepter adit to the Sunburst workings. Electric power has been secured and it is expected to complete the raise inside of 60 days.——A body of mineralized quartz 18 ft. wide has been encountered in the C. & H. adit on Covode mountain. The find was made on the Surprise vein cut 130 ft. from the portal. Tests just made show 2.40 oz. gold and 4 oz. silver per ton.

Georgetown, March 18.

(Special Correspondence).—Work was put under way last week by the Gilpin-Imperial M. Co., operations being conducted through the Newhouse adit. Three lode mining claims are controlled, the property was intersected 14,000 ft. from the portal of the adit.——The Little Mattie mill up Chicago creek is running night and day and a heavy tonnage of concentrate is being marketed.——The Stanley mine will shortly be classed among the heaviest shippers in the county. In addition to tributors, James Bowden, the manager, is employing a big force of company men, work being centered on the second level. Returns of from $45 to $50 per ton are being realized.——Warren & Co., leasing on the third level of the Shafter mine, have found a streak of smelting ore that is from 6 to 10 in. wide and assays 9.80 oz. gold to the ton with 20% copper.

Idaho Springs, March 19.

GILPIN COUNTY.

(Special Correspondence).—The Gunnell mines at Black Hawk were sold last week to foreclose under a bond issue in favor of the Federal Trust Co. of Boston. The property was bid in for $300,000.——The Quaker City mine on Quartz hill has been taken under lease by a pool of local miners. The shaft, down 200 ft., is to be sunk another 100 ft., and day and night shifts will be employed.——Work is to be resumed on the Golden Sun property up South Boulder creek April 1; E. T. Butler, of Denver, will be in charge.——The new shaft building on the Alps mine in the Nevada district is about completed.——D. S. Davis is employing a force of men in the development of the Russell mine. During the last week a 12-in. streak of copper-iron ore was uncovered on the 200-ft. level that will mill from $40 to $45 per ton in gold. There is also exposed a body of mill ore that is 4 ft. wide.——The Fifty Gold Mines Co. sold last week 107 oz. gold that brought $1800 at the Rocky Mountain National Bank.

Central City, March 17.

TELLER COUNTY.

The Cresson is worked on company account and production is on the increase.——Fred Johnson and his associates, principally Denver men, who have worked several years and spent thousands of dollars on the Pride of Cripple Creek property, on Ironclad hill, are reputed to have made one of the best finds in the district. A small ore-shoot was encountered some months ago and development was commenced in earnest. Only the ore mined in the course of development was shipped, but it gave splendid returns.

IDAHO.

IDAHO COUNTY.

Central Idaho is excited over discoveries near Elk City. The Harmon & Morrow claim is being examined by A. W. Harvey for J. C. Haas, of New York.——The Center Star group has been bonded to B. Binnard & Co., of New York, for $100,000.——Orders have been issued for the construction of 40 miles of the Gilmore & Pittsburg railway from Salmon City west.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—One of the largest purchases made in the district for some time is that of the Old Dominion Co., which has procured 660 acres of land in fee in the Joplin district and 700 acres of leases in Oklahoma, west of Seneca. Of this, 20 acres lies northeast of Turkey creek, where profitable mining has been carried on by several companies. A large amount of drilling and development was done here last year, and two shafts were sunk into a valuable orebody. Among the mines situated in the immediate vicinity are the old Dividend, the old Cardinal, the Green Dog, and the Kalitan. The rest of the land purchased lies between Wentworth and Ritchie. The plans for the new holdings involve the immediate development of the 20-acre tract along Turkey creek by drilling. The tract near Ritchie will be subleased under attractive terms to force its development. The company already owned a large acreage scattered over the district as well as many leases. The company is one of the largest and most active in the district.——The Green Dog Co., operating along Turkey creek, has after long development reached a good productive stage. The company now has three shafts in ore at 85 ft., where a 12-ft. face is opened. The orebody seems to be 300 ft. long and 35 ft. wide. The entire tract has been extensively mined for shallow mineral and the ground is honeycombed with old shafts and drifts. The old mill has been overhauled and almost doubled in capacity, now equalling 250 tons.

Joplin, March 17.

MONTANA.

MADISON COUNTY.

The Conrey Placer Mining Co. has contracted with the Marion Steam Shovel Co. for a new dredge. Construction is to begin April 15, and the machine is to be completed November 1. The hull will be 150 ft. long, 58 wide, and 13 deep. The bucket chain will contain 80 buckets of 15-cu. ft. capacity, each weighing 4200 lb. The dredge will have a stacker 130 ft. long, and two spuds each weighing 45 tons. The capacity is to be 300,000 cu. yd. per month, and 1050 hp. will be needed.

NEVADA.

CLARK COUNTY.

Late reports from Alunite confirm the news of an important discovery of high-grade ore. The company has stopped work and is giving out no information. It is known that rich sulphide ore similar in character to the Goldfield high-grade has been found. Robert T. Hill has been summoned from New York by wire.

DOUGLAS COUNTY.

An electric plant is to be installed at Minden by W. H. Metson and P. O. Chappelle, who control a water-power site. They have recently let a contract for a 1500-kw., 2200-volt, 3-phase, 60-cycle, 400-r.p.m. water-wheel type alternator; two 65-kw. motor-generator exciter set; a 65-kw. direct-connected exciter unit, and six 200-kw. 55,000/2200-volt oil-filled self-cooled transformers to the Allis-Chalmers Company.

EUREKA COUNTY.

The Buckhorn Mining Co. has a partly developed gold mine 28 miles southeast of Beowawe, and it is reported that a crushing mill and cyanide plant is to be erected on the property. F. J. Siebert is connected with the company.

HUMBOLDT COUNTY.

(Special Correspondenc).—The National mining district, in which the town of National is situated, is 75 miles north of Winnemucca. The town is 7 miles south of the Oregon State line, at an altitude of 7000 ft., and has a population of about 400 people. Stages and automobiles are run daily between the two places. The richest ore was mined by Stall Bros., who had a lease on the group known as the National of Nevada, which produced about $150,000 in gold and silver last year. Returns from the Selby smelter show that 106½ lb. of ore yielded $8149; 188 lb. in another lot brought $10,719; 121 lb. returned $9531. A larger shipment, 2503 lb., brought $6858. The ratio of gold to silver in these shipments was 1 oz. gold to 1 oz. silver. The high-grade

came from a seam in the vein that was comparatively narrow, while the wider part of the vein carried gold associated with antimonial silver, and some cinnabar. This property was developed by a system of levels on the vein from the mountain side. Work has been suspended several months for a suit which is pending. Stall Bros. claim the right to an extension of their lease, which, they assert, was promised them by the former directors; the new board is trying to dispossess the lessees. Adjoining the property mentioned above is the First National, controlled by S. W. Gundaker and associates; still another is the National Consolidated, in which Seattle men are interested. Several lessees are at work on the latter, and they are reported to have cut the famous Charleston vein from which the high-grade ore of the camp was taken. The Radiator is under bond and lease to Cummings, Dwyer and O'Connel, who are said to have made a payment on the price named in the bond. A shaft is being sunk on the Workman group on Auto hill, by Phil Blume and associates, who have installed a gasoline hoist. The shaft is down 300 feet.

Winnemucca, March 20.

LYON COUNTY.

(Special Correspondence).—The Nevada Copper Belt railroad, built by the same interests which control the Nevada-Douglas Copper Co., extends from Wabuska to Mason, a distance of 14 miles, the latter being 2 miles southwest from Yerington, and 1½ miles east of the Mason Valley mine. This line is being extended, the route running 8 miles south of Mason, through a pass into Smith valley, thence north 10 miles to the Nevada-Douglas mines, which include the Ludwig. A gasoline motor car, for passenger traffic, operates between Wabuska and Mason. The smelting plant, the construction of which is being planned, is an enterprise of the Mason Valley Copper Co., which has selected a site one mile north of Wabuska. It is assumed that this smelter will treat ore from all the mines of Yerington district.——The Nevada Mining, Reduction & Power Co. is operating a mine and an 18-stamp mill at Silver City, and is erecting a 40-stamp mill and cyanide plant at Rock Point, close to Dayton. The structure is of steel. Herman Davis and W. B. Sayers, of Dayton, are active in the management.

Yerington, March 19.

NYE COUNTY.

(Special Correspondence).—The orebody recently opened in the lower workings of Montgomery-Shoshone is good, but lacks the sensational richness with which it has been credited. The mill is running steadily. Most of the ore is coming from the glory hole, with about 250 tons per month from the Polaris.——The Goldfield Reduction Co. has entered the market for the buying and treatment of local ores. ——Most of the machinery has been installed at the Bonnie Clare mill, and it is expected to have the plant in operation within 30 days.——The tunnel of the Bullfrog Gold Centre Co. is in 610 ft. and will be driven to 6500 ft. Four veins have been intersected.——The Nevada ore mill at Beatty has been completed. The initial run will be made on a carload of Pioneer ore.——The machinery for the Eclipse mill has arrived. It is expected to commence crushing within a few days.——The Sunrise Pioneer lease on Pioneer Con. estate has opened 10 in. of rich ore. At a depth of 220 ft. the main vein has been cross-cut 20 ft. and runs into milling grade.——The shaft on the Pioneer lease is being sunk to the 400-ft. point. Fifteen to twenty tons of ore worth about $100 per ton is being produced daily. A like amount assaying $15 to $20 is being placed on the dump.——The Gillespie and Dougherty leases on the Jim Butler are developing shipping ore. The shoots run about 1 ft. wide. Two machine-drills are used on the Gillespie lease.——The Montana-Tonopah company has secured options on the Afterall, North Star, and Miriam claims.——W. H. Bond has opened a strong vein on Bare mountain. It is said to run 50 ft. wide, about 20 ft. assaying $40 per ton. It was uncovered at a depth of 2 ft.——The Manhattan Thanksgiving has opened a 5-ft. vein at a depth of 450 ft. assaying $20 per ton.

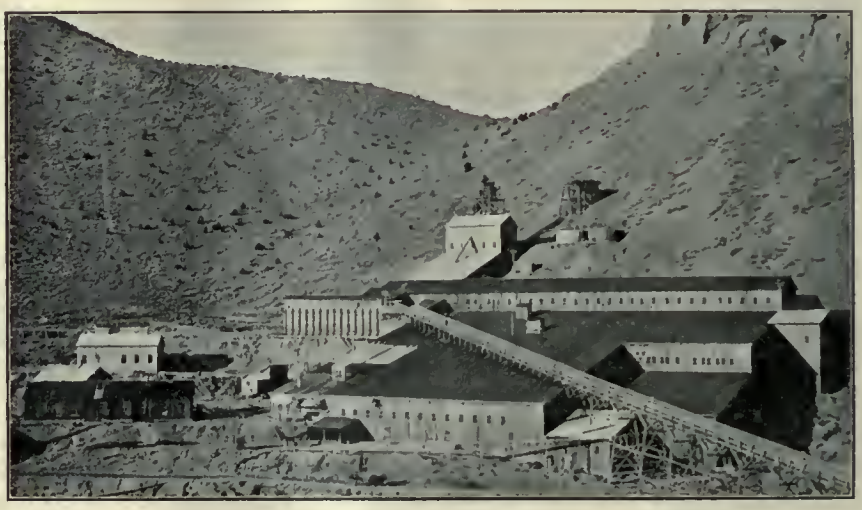
Rhyolite, March 17.

(Special Correspondence).—Round Mountain now has a larger reserve tonnage than ever before. The monthly bullion returns are about $25,000 to $40,000. Quarterly dividends aggregate $260,000 to date.

Round Mountain, March 19.

STOREY COUNTY.

(Special Correspondence).—The Charles Butters Co., Ltd., which purchased the Monte Cristo claims in Seven Mile canyon, below Virginia City, expects to open the orebody thereon and build a surface tramway from that property to the mill. The 160-ft. shaft is to be sunk deeper. This company is still operating on the Chollar and Potosi as lessees, and will begin shipping again from these workings April 1. Recent work there consists of a winze that was sunk 133 ft. below the 218-ft. level. The Butters cyanide plant has resumed work on the Ophir tailing, which contains gold and silver worth from $3 to $6 per ton. At present 150 to 200 tons per day are being treated. Later the company's 20-stamp mill will be started to concentrate the ore from the Chollar and Potosi leases. S. M. Stone is general superintendent.



Butters Plant, Virginia City.

Virginia City, March 21.

NEW MEXICO.

SIERRA COUNTY.

(Special Correspondence).—The Morrison crusher recently installed at the Keystone property has begun work and a cyanidation plant is to be built. Most of the machinery is on the ground. An experimental treatment plant will be built also for testing other ores.——The station at 200 ft. in U. S. Treasury shaft No. 1 is about to be cut. The Gold Reserve group is being examined for Alabama people.——Jobe & Son, operating the Eureka near the Keystone, have 15 men at work and have ordered lumber for bunk-house and other buildings.——The U. S. Treasury company will build a telephone line from Chloride to shaft No. 1.

Chloride, March 19.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Homestake is running full, and recently hoisted 5292 tons in 24 hours. The regular monthly dividend has been declared.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—During February the Republic Mines Corporation shipped 15 carloads of ore, and other lessees shipped two from the Lone Pine No. 4, both belonging

to the Pearl Consolidated Mining Co.——The Tom Thumb mine, owned by the Midget Gold Mining Co., and leased, with an option to purchase, by The New Republic Co., has been sublet.——The New Republic Co. recently elected a new board of directors, with R. J. Howard as vice-president and general manager.——The prospects in the Southern Republic mine are quite encouraging. Samples assay from $23 up to $90 per ton.——The Ben Hur mine is sending four carloads of ore per week to the Granby smelter, at Grand Forks, British Columbia.

Republic, March 19.

OKANOGAN COUNTY.

(Special Correspondence).—The Palmer Mountain Tunnel & Gold Mining Co.'s directors are planning to liquidate, dismantle the plants, and dispose of the material on hand; minority stockholders object.——The necessary capital has been secured and work will be resumed immediately on the Golden Chariot mine on Kruger mountain. The main hoist will be installed and the shaft will be sunk 200 ft. deeper. The shaft follows the vein, which maintains an average width of six feet.——The Molson Mining Co. has sunk a shaft on the Poland China mine 135 ft. and is driving both ways.——Work on the Jim Hill group, on Copper mountain, near Chesaw, will be suspended until quarters can be built for a larger force. The shaft has been sunk 91 ft., and three drifts have been driven, finding ore of excellent quality. An adit will be started farther down the hill, to be eventually 11,000 ft. long. A short wagon-road is under construction, connecting with the Grant road.

Conconully, March 18.

STEVENS COUNTY.

(Special Correspondence).—A new gasoline hoist is being installed at the Swamp King mine, near Orient. The shaft has exposed a 5-ft. vein of free-milling ore.——The Napoleon mine is again in operation. The British Columbia Copper Co. is expected to begin soon the construction of a smelter about two miles north of Godfrey, on the Kettle river, for the reduction of Napoleon ore.——The Orient Gold Mines, Ltd., has been incorporated, with a capitalization of $1,500,000. The incorporators are Frank Ansley, A. B. Railton, and Charles J. Johnson, of Spokane.——W. J. Caplin, of Orient, with J. S. Payne, H. E. Wadsworth, and E. J. Merrin, of Spokane, have organized the Orient Mystery Gold Mining Co., to operate the Eagle, Mohawk, and Mystery claims, near the head of Pierre lake.——The Germania Mining Co. has spent $250,000 during the past four years on its property near Deer Trail. The company owns two quartz claims, on which tungsten ore is mined, and a section of land, all patented. This company, financed by the Krupps, of Essen, Germany, is now employing 60 men on its tungsten property.

Colville, March 19.

WISCONSIN.

Geological students from the University of Wisconsin have been visiting the zinc mines near Hazel Green, Cuba, and Livingston.

MEXICO.

CHIHUAHUA.

The Rio Plata Mining Co. has declared a 2% quarterly dividend. The balance of the indebtedness on the property has been paid out of earnings. The mine is situated in the southwestern part of Chihuahua, 85 miles across the Sierra Madre from Sanchez on the Kansas City, Mexico & Orient railway, which will run within 20 miles of it when completed. It was discovered six years ago by Rudolfo Cruz, who sold to the present owners.——Concentrate assaying 1000 oz. silver, is being shipped by pack-mules to the railroad. Since the present owners took charge about 700 tons of concentrate have been shipped as well as silver bars from the cyanide plant. The output at present is approximately 1,000,000 oz. annually.

OAXACA.

(Special Correspondence).—The famous San Juan case has been settled. By a unanimous vote of the Federal Supreme Court, C. A. Hamilton has received confirmation of the decision of the lower court. This places Mr. Hamilton again in possession of the property, with right to demand accounting for the proceeds of the mine.——Tavichе is being examined as to tonnage, grade of ore, and treatment methods, with reference to a proposed custom mill.——A corps of engineers of the National Lines of Mexico is making surveys beyond Tlacolula, toward Tehauntepec, and the line to Tlacolula is now being extended from Oaxaca.——The recent failure of the U. S. Banking Co., with the possibility of a long delay before any settlement is effected, caused a number of mines to close.

Oaxaca, March 17.

SONORA.

(Special Correspondence).—The La Dura Mining & Milling Co., operating the Gloria and Prieta mines at La Dura on the Yaqui river, has sunk a 1040-ft. vertical shaft at the Prieta and 1300-ft. incline at the Gloria. Both properties are producing high-grade silver ore, with a little gold, copper, lead, and zinc, though the latter is so trifling that the company has never been penalized for its excess in shipments to the smelters. The country rock is andesite, and the ore is found in a quartz gangue. At the Gloria the ore dips about 60°, and the fissure is very regular, but at the Prieta a second series of faults has left the ore in terraces. The force that caused the second faulting operated when the vein was comparatively flat and raised the central portion above the terraces on both sides. In following the slips down from one body to the next the management has found that there is approximately 6 in. of gouge for every 25 ft. of displacement, and in this way can roughly determine the position of the ore which now has a dip of from 10 to 15°. A later cross-faulting has broken the vein slightly, though not enough to seriously affect mining operations. The water in the Prieta only amounts to 1800 gal. per 24 hr., although it is several hundred feet below the level of the Yaqui river. There is a concentrating mill on the property, the capacity of which varies from 60 to 100 tons per day, according to the grade of the ore. Both mines are equipped with hoists and compressors which were packed in on mule-back. A German make of air-drill is used, the bit being Z-shaped, and the effect is more one of boring than drilling by percussion. The work is done largely by contract with Mexican laborers or Yaqui Indians, who sort the ore underground. They are excellent judges of the grade of ore, and sort to within an ounce or two of what the contract calls for. In other portions of the work only the drilling is done by contract, the laborers receiving 20 centavos per foot for machine-work and 37½cv. for hand-drilling. The hand-drillers sharpen all their own steel, and the machine-men use a file on their bits till the gauge is completely gone, when the company's blacksmith sharpens them. Wood costs the company ₱5 per cord of 4 by 6 by 6 ft. delivered at the mine, and must weigh at least 1500 kg., or the contractor is docked. It is all hardwood and makes an excellent fuel for steam and domestic use.

La Dura, March 13.

PHILIPPINE ISLANDS.

The Stanley dredge on Paracale river is handling 1500 cu. yd. per day and getting about 60 oz. gold per week, according to John Gilles.——George Laduc has organized a company to work the Australiano and Navotas claims in the Mambulao and Paracale districts.——The Paracale Gold Dredging Co. has begun work on a number of quartz claims recently optioned.——R. E. Kent is now foreman for the Benguet Consolidated. Mr. Kent had extended experience in the Rocky Mountain States, but came to the Philippines from Korea, where he was with the Oriental Consolidated.——Prospectors have left Manila for Surigao, the Cogayan River district in Misamis, and other points in the neighborhood of Iligan, Llanoa district, where placer deposits are attracting attention. The gold now in the native diggings is coarse. Nuggets worth ₱50 to ₱100 are occasionally found.——American prospectors have found placer deposits in the Nueva Ecija, province of Luzon. The gravel contains 30 to 80c. per cubic yard as far as prospected, and 10,000 acres are involved. Of this, 1500 acres has been tested and found to contain 33 to 62c. per cubic yard. The ground is adapted to dredging.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. F. KEMP was at Butte.

J. R. FINLAY was in San Francisco this week.

RALPH ARNOLD was in San Francisco this week.

W. SPENCER HUTCHINSON has returned to Denver.

WILLIAM W. ROSE was in San Francisco last week.

LLEWELLYN HUMPHREYS, of Salt Lake, is in the East.

J. M. CALLOW has returned to Salt Lake from the East.

D. J. KELLY, of the Kelly Filter Press Co., is in Mexico.

S. F. SHAW has been recently examining gold mines in Alabama.

E. A. ZEISLOFT, of Shoshone, Idaho, has removed to Vale, Oregon.

H. G. GILKERSON has taken new offices in the Boston Bdg., Salt Lake, Utah.

ROBERT H. RICHARDS has returned to Boston from a professional trip to New York State.

W. G. ADAMSON, of Winnemucca, Nevada, is expected back from Philadelphia by April 1.

O. H. PACKER is at Santa Rosa as an expert witness for the Cecelia Magnesite Mining Company.

FRANK BURNS, of the Arkansas & Arizona Copper Co. at Jerome, Arizona, has gone to Guanajuato, Mexico.

S. H. BROCKUNIER arrived in San Francisco from Wheeling, West Virginia, and has gone to Graniteville, California.

W. G. EBERHARDT, of Ridgefield Park, New Jersey, was recently in Humboldt county, Nevada, on examination work.

C. A. FISHER has resigned from the United States Geological Survey to enter private work in partnership with Ralph Arnold.

KARL P. SWENSEN sailed for Nanking, China, on the *Korea*, March 21. Mr. Swensen goes to take a position in the School of Mines of Nanking University.

R. B. LAMB has returned to New York from Costa Rica, where he has been making examinations for C. L. Constant Co., and is immediately going to Chihuahua, Mexico.

F. G. CLAPP delivered a paper on March 9 before the Geological Society of Washington on 'A Proposed Classification of Petroleum and Natural Gas Fields Based on Structure'.

WILLIAM R. JEWELL has returned to San Francisco from the Midway, Maricopa, and Devil's Den oilfields, where he has been making examinations for the General Land Office.

Obituary.

GEORGE E. WOODBURY died in San Francisco on March 17. Mr. Woodbury was one of the prominent figures in the mining activities of the West for many decades. He devoted his energies and mechanical talents to the development of milling methods, and particularly to concentration. He made improvements in the Frue vanner that received wide approval, and he also invented a riffle-table concentrator that acquired a good reputation. He was one of the 'old school' of whom but few remain.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the month of January 1910:

	Tons.
Imports of copper	15,273
Exports of copper	523
Consumption	14,750

as compared with consumption during the same period in 1909 of 11,237 tons. Of the above quantity 13,993 tons were imported from the United States.

THE RIO PLATA MINING Co., March 8, declared a quarterly dividend of 2%, payable to shareholders of record March 19.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONVEYANCE OF MINERALS—RIGHT TO SURFACE.

The grant of coal or the conveyance of a coal mine, under the surface, carries with it the use of the surface so far as it is necessary to carry on mining operations.

Gordan *v.* Park, (Mo.) 117 Southwest. 1163, April '09.

OIL AND GAS LEASE—VESTED ESTATE.

The interest of a lessee in oil and gas under a lease by which oil and gas in certain described premises are granted to him with the right of entry for drilling purposes, becomes vested on the discovery of oil and gas.

Ramage *v.* Wilson, (Ind.) 88 N. E., 862, June '09.

ENJOINING OPERATION OF MINE.

Injunction will lie to prevent a mine owner from carrying on his mining and persisting in a mode of mining which endangers the support of the surface, and thereby endangers the safety of railroad tracks on the surface.

Southwest Missouri R. Co. *v.* Big Three Min. Co., (Mo.) 119 S. W. 982, June '09.

LOCATION OF MINING CLAIM.

Under the United States statutes possessory title to a mining claim can only be acquired by a valid location. An essential of possessory title to a mining claim is the discovery of minerals thereon. Where the locators of two association claims, which overlapped, were sinking shafts at the same time, the first to discover mineral has priority of right, although the location was staked after the other, if made openly and peaceably.

Hanson *v.* Craig, 170 Fed. 62, May '09.

OPERATION OF COAL MINE—SUPPORT OF SURFACE—WAIVER.

Where a deed by which mineral rights were conveyed to another stated that it was mutually agreed that the grantee should not be responsible for injury to the surface resulting from removing the minerals, the grantor thereby waived his right to recover damages for injury to the surface caused by operating the mine. The implied right of the surface owner to support does not alone determine the rights of the parties; but the instrument by which the conveyance of the minerals is made controls where it makes definite provisions as to the rights of the parties.

Paull *v.* Island Coal Co., (Ind.) 88 N. E. 859, June '09.

MACHINERY FOR DRILLING OIL AND GAS WELL NOT A FIXTURE.

Machinery placed on lands leased for gas and oil purposes do not become permanent fixtures nor parts of the freehold because of such annexation to the land as was necessary to develop the premises according to the terms of the lease; and even on a forfeiture of such lease, such machinery does not vest in the lessor. But where such a lease authorized the lessor to remove the fixtures at any time, the right was said not to be unlimited as to time, but the lessee was only entitled to remove such machinery within a reasonable time after the expiration of the lease.

Perry *v.* Acme Oil Co., (Ind.) 88 N. E. 859, June '09.

COAL LANDS—RIGHT TO COAL REMOVED DURING DEVELOPMENT WORK.

Under the United States statutes a qualified person who, in response to the Government's invitation, enters upon public lands in search of coal deposit and who expends time, labor, and money in an honest effort to open and develop a coal mine when found, and with the intention of purchasing the lands according to the statute, if the coal discovered proves to be such as to give character and value to such land, was said not to be a trespasser, but on the contrary was in the exercise of a privilege conferred by law and entitled to such coal as was taken out and removed as an incident only to the reasonable prosecution of that work.

Ghost *v.* United States, 168 Fed. 841, March '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

RECONNOISSANCE OF THE GYPSUM DEPOSITS OF CALIFORNIA. By Frank L. Hess. U. S. Geol. Surv., Bull. 413. Pp. 36, ill., index. Washington, 1910.

A brief but helpful report accompanied by a map of localities and a chapter by George Steiger on errors in chemical analysis of gypsum.

PROGRESS OF THE MINERAL INDUSTRY OF TASMANIA. By W. H. Wallace. Pamphlet. Pp. 20. Hobart, 1909.

This report was made by the Secretary of Mines to the Minister and covers the quarter ended September 30, 1909. The total value of the output was £404,729 with blister copper £157,639 and tin ore £111,579, in the lead.

THE FIRE TAX AND WASTE OF STRUCTURAL MATERIALS IN THE UNITED STATES. By H. M. Wilson and J. L. Cochrane. U. S. Geol. Surv., Bull. 418. Pp. 30. Washington, 1910.

A careful and valuable study of a source of loss of $456,485,000 in the United States in 1907. Nearly one-half the value of all new buildings constructed in a year are destroyed by fire. The subject is certainly deserving of study.

TRANSACTIONS AUSTRALASIAN INSTITUTE OF MINING ENGINEERS. VOL. XIII. Pp. 213, ill. Melbourne, 1909.

This modest little volume indicates that the Australasian Institute is doing a large amount of excellent work. The seventeen papers included range from the presidential address on Professional Idealism by C. F. Courtney to a discussion of Kalgoorlie stoping methods by J. Cheffirs, with many good things between.

IOWA GEOLOGICAL SURVEY, VOL. XIX. ANN. REPORT. 1908. Samuel Calvin, State Geologist, James H. Lees, Assistant State Geologist. Pp. 806, ill., index. Des Moines, 1909.

This volume contains a general resumé of existing information regarding the coalfields of Iowa. The last preceding report on this subject was that forming Vol. II of the present series, and was prepared by C. R. Keyes and assistants in 1893. Since then information regarding the stratigraphy of the State has advanced materially, but, perhaps, improvements in technology of coal testing and coal using have made equal progress. Both lines of research are well represented in this volume, Frank A. Wilder, Henry Hinds, and A. Dixon, discussing fully the results of the tests made at St. Louis in co-operation with the United States Geological Survey. The report is an excellent general summary at the same time that it contains much information that is new and valuable.

IRON ORES, FUELS, AND FLUXES OF THE BIRMINGHAM DISTRICT, ALABAMA. By E. F. Burchard, Charles Butts, and E. C. Eckel. U. S. Geol. Surv., Bull. 400. Pp. 204, ill., index, map. Washington, 1910.

The report sketches the general geology of this region, discusses the origin and geologic relations of the iron ores, and describes the numerous deposits. The methods of mining and prospecting are also described. In the section on fuels the available quantity and the composition of the coking coals are discussed, as well as the methods of coking and the character of the coke. The limestones and dolomites that are used as fluxes are also briefly considered. Since 1894 Alabama has held third place among the iron-mining States and in 1909 produced more than 4,000,000 long tons of ore. Of this total product the Birmingham district produced over 3,000,000 tons. Practically all this ore is made into pig iron in the Birmingham district, in which there are 29 coke furnaces. The ores, broadly considered, are of two kinds—red or Clinton ore and brown ore. Seven-eighths of the ore mined in the district is red ore. It is estimated that 500,000,000 tons of the red ore is available for mining by present methods—a supply that will last more than a hundred years. The report is a valuable and welcome addition to the literature of the iron industry.

Colorado Mineral Production in 1909.

Figures showing mineral production in Colorado for 1 909 by counties are given below. They are for the year ended December 31 and are furnished by T. J. Dalzell, State Commissioner of Mines.

COLORADO	GOLD		SILVER		LEAD		COPPER		ZINC		TUNGSTEN		TOTAL
Name of County	Fine Ounces	Value	Fine Ounces	Value	Pounds	Value	Pounds	Value	Pounds	Value	Tons	Value

Note.—In the above table the calculation is on the average market price of the minerals for the year.
Gold, 20.67; Silver, .515; Lead, .04273; Copper, .121; Zinc, .055. The Zinc figured on actual spelter recovered.

Commercial Paragraphs.

T. H. Proske recently shipped two 25 ft. D 24 Ajax drill sharpeners to the India Government for use on irrigation projects in India.

The Robins Conveying Belt Co. has moved its general offices to the Park Row Bdg., 13 Park Row, New York. The branch office at 30 Church street will be discontinued.

The Denver Engineering Works Co., Denver, Colorado, announces that L. G. E. Bignell, at one time manager of the Salt Lake office, and recently manager of the El Paso office, has been appointed sales manager at the Denver office; L. P. Hammond, former sales manager, having resigned to take a similar position with the Central Colorado Power Company.

The Sullivan Machinery Co. reports that it is installing four of its tandem Corliss compound steam and two-stage air-compressors for the Mason & Hanger Co., at Cornwall, New York, where the above company has a contract for one of the siphons or tunnels for the New York Board of Water Supply. Each of the above units has a capacity of approximately 2500 cu. ft. of free air per minute, so that the completed plant will furnish 10,000 cu. ft. of free air per minute.

The Pacific Tank & Pipe Co. is the name under which the business and manufacturing plants of the National Wood Pipe Co. and the Pacific Tank Co. have been consolidated. The officers and employees of both concerns have been retained, and all contracts and obligations will be assumed by the new company. The largest pipe and tank factory in the world has just been completed at Portland, Oregon, which, with the two factories at San Francisco and Los Angeles, gives most excellent facilities for execution of all orders. It is certain that the high standard set by the two companies in the past will be maintained by the consolidation.

The Hardinge Conical Mill Co., New York, last July placed one of its 8-ft. Hardinge mills on trial with the Calumet & Hecla Co., of Michigan, to be operated in competition with Chilean mills. The result of a six months' trial is the adoption of the Hardinge mill and the signing of a contract between the Hardinge Conical Mill Co. and the Calumet & Hecla Co., whereby the latter company controls the right to manufacture and use the Hardinge mills in all its plants. General Manager MacNaughton writes that the Hardinge mill is the "best fine-grinding device they have ever gotten hold of." This statement coming from such a critical source is a thing of which the Hardinge company is justly proud. Another company in the same district, after three months' trial, has accepted a mill, and has entered an order for a further installment. In one instance fine slime grinding was required, and in another a coarser concentrating product was desired. Now a third company has placed an order, and a fourth has signified its desire to follow the lead of the others. In all instances the Hardinge mill is doing the work formerly performed by Chilean mills of different designs.

Bone ash for assay work, according to a booklet issued by the Denver Fire Clay Co., of Denver, Colorado, should be manufactured especially for that purpose, since grades available for case-hardening and other purposes are not suitable for assaying. This company began manufacturing bone ash in 1876. Only the cleanest carefully sorted bones are used. The bone ash made by this company is marketed in three grades, X, XX, and XXX, put up in 25, 50, and 100-lb. boxes and 500-lb. barrels, all securely lined to prevent loss from leakage. All three grades are made from the same quality of bones, but they differ from each other in the fineness of particles. Grade X is the coarsest, XX somewhat finer, and XXX the finest. Bone ash is not graded by mesh, as material of uniform size will not make a satisfactory cupel. Material of varying degrees of fineness must be present in natural proportions in order that the interstitial spaces be practically filled. Thus the occlusion of air and moisture is minimized, aside from absorption. A cupel made of such material will be homogeneous and will work without cracking. Practically 75% of the X grade will pass a screen aperture of 0.0147 in. (approximately 40 mesh), the XX 0.0091 in. (approximately 60 mesh), and the XXX 0.00675 in. (approximately 80 mesh). These sizes cover the general requirements of a perfect cupel.

EDITORIAL.

NEVADA, long known as the silver State, is now constantly claiming attention by reason of discovery of rich gold ore. The region around Battle Mountain, in Lander county, has attracted especial attention this year, and we are glad to present this week a brief description of Kimberly, written by Mr. Jay A. Carpenter of the Mackay School of Mines at Reno. The district is obviously one which, like the proverbial rat-hole 'will bear looking into', though for entirely different reasons.

CHEMISTS are already preparing for the eighth International Congress of Applied Chemistry which is to meet in the United States in 1912. At a meeting held in New York, representatives of the Association of Manufacturing Chemists, the American Chemical Society, American Electrochemical Society, and the Society of Chemical Industry, a preliminary organization was effected with B. C. Hesse, 90 William street, New York, as secretary. All working chemists are invited to take part in the organization of the Congress and suggestions, which may be sent to the secretary, are invited.

APPARENTLY the set-back which the silver miners received when the Indian Government suddenly placed an additional import tax upon silver will not be lasting. The prompt recovery in the price showed that the East Indian must have silver, even though the price be raised 10 per cent, as it has been by collecting a duty of four annas per ounce. It is also pointed out that temporary reduction in the price of the metal always provokes an immediate response in the shape of increased exports from China. This soon necessitates a sharp demand for silver to cover such foreign receipts of Chinese merchandise. Thus the effects are compensating. The momentary decline in the price of one-fourth cent per ounce is nothing more than a reflex of current market demands.

INSURGENCY has been rampant of late, and achieved a notable result in the reorganization of the House Committee on Rules at Washington, with the exclusion of the speaker. The new committee is sure to be more amenable to public opinion and yet is not too large to be effective. In the vote determining the matter only one California Congressman voted against the speaker. Things may be different in another Congress, as Mr. Hiram Johnson, the 'insurgent' candidate for Republican nomination for Governor, is making a brilliant and effective canvass. One of the humors of the present situation is the condition in Illinois, where the progressive Governor, Mr. C. S. Deneen, recently made a strong plea

for party harmony in addressing a meeting of Republican editors. The humor lies in the fact that in this State it was the old guard which bolted the eausus, and united with party opponents in order to prevent enactment of progressive legislation promised in the platform. Bolting is a serious crime until your side is in the minority, and then it becomes "a patriotic duty." This is another way of saying that human nature is much the same in 'stand-patters' and 'insurgents'. The truth is that the public is coming to care less for fidelity to party as applied to an organization or a group of leaders, and more to fidelity to a party program. This is as it should be and will work out for better government.

TENNESSEE is to have a State Geological Survey, and has made excellent choice in selecting Mr. G. H. Ashley for Director. Mr. Ashley is a graduate of Cornell and Stanford Universities who has had extended experience in connection with the Arkansas, Indiana, and United States Geological Surveys. He is a specialist in the geology of coal and has made important contributions to that subject. He will find in Tennessee an excellent field. Broad foundations for geologic work were laid there half a century ago by Mr. J. M. Safford. The Civil War interrupted this, as it did much other important work, and in recent years Tennessee has seen her neighbors outstrip her in official scientific work and in development. Under Mr. Ashley both the scientific and the economic features of the geology of the State are sure to be properly studied and presented.

CONE CLASSIFIERS have come rapidly into use, replacing the old fashioned wooden pyramidal spitzkasten and spitzlutten. They are more efficient because the length of their overflow, which is three times as large as that in the usual pyramidal classifier, reduces the velocity of the stream in inverse proportion and better settling is secured. Their use with peripheral overflow launders naturally involves central inflow. The various difficulties met in maintaining a constant flow with this form led to the development of the Caldecott diaphragm cone described elsewhere by Mr. Walter Neal. It has been principally used on the Rand and previous descriptions have been based on work in South Africa. The account of results obtained with it in Mexico will therefore be especially welcome to metallurgists.

TONOPAH is to be re-surveyed geologically. The original mapping of the district was done by Mr. J. E. Spurr, for the United States Geological Survey. His work has received many compliments and was indeed a masterly study of an exceedingly difficult area. It undoubtedly did much to guide development. Being made when the mines were shallow and the deeper horizons were still unexposed, there naturally is now much to be seen which could then only be guessed. Mr. J. A. Burgess, geologist for the Tonopah Mining Company, Mr. E. M. Jenney, and others have raised important questions regarding principally the intrusive or extrusive character of certain lower rocks. Promptly, and with a commendable spirit of co-operation, the leading companies, the Tonopah, the Montana Tonopah, the Belmont, and the Midway have joined in inviting Mr. Spurr to re-study the district at their expense; all of which is a pleasant recognition of the value of expert advice and a compliment to Mr. Spurr.

LOST-MINES are a sort of negative asset to an enterprising mining district. The 'burnt cabin' mines, and the 'peg-leg' mines, and others of like attractive appellation, keep fresh the glow of romance, and exert their lure upon the minds of impressionable capitalists. The Bulletin of American Republics reminds us of the lost mine Panama, the ancient Tisingal, which still eludes the searcher on the slopes of Chiriqui. Gold mines have played an important rôle in Darien and at other points on the Isthmus. Now that the Tisingal legend has been polished anew speculators will certainly look more eagerly in that direction.

Coal-Land Prices.

Coal-land prices were raised materially this year by the Department of the Interior on the basis of new valuations made by the Geological Survey. The Spokane branch of the American Mining Congress has passed resolutions objecting to this and pointing out that the increased sum must ultimately be paid by the consumers of coal, who will naturally be the people living in the Western States. It is entirely true that the increased price at which the land is held will finally enter into the price of the coal as delivered, but the ultimate consumer is likely to buy the coal for less if the land be held for the new price than if the old rate of ten and twenty dollars an acre had been maintained. At the latter the land was rapidly passing into the hands of speculators. At the new rates the ownership remains with the Federal Government up to the time that there is a real demand for the coal; then it becomes profitable to buy the land and mine. While the Government holds the land there is no accumulating interest charge, and so far there has been no argument to the effect that the new prices were more than the real value. When speculators hold the land interest charges accrue and prices are, naturally, fixed at the highest possible limit. It is customary to buy coal land, bond it for as much as an optimistic bond buyer can be induced to stand, and then load the enterprise with sufficient stock to absorb any possible profits above the interest charge. It will be cheaper in the long run if the Government hold the coal lands, parting with them only as coal is actually needed. This would be true even if it were necessary to issue public bonds against the land. The Government can always borrow money at a less rate than can an individual, and in the future price of coal interest charges are sure to be important. Fortunately the Government does not need to issue bonds in order to hold the lands and there is no need to resort to a supposititious case. Sharp discrimination should be made between purchase of public land for actual present-day development and for speculation. The new prices do not hinder the one but they do, and properly, discourage the latter.

Patents and Progress.

Inventors are no longer content to be considered long-haired luckless visionaries. The International Congress of Inventors, founded in 1906, and now including over a thousand members, announces that its first annual convention and exposition of patents and models will be held at Rochester, New York, June 13 to 18. Both the convention and the exhibition are sure to be interesting. Americans have been especially proud of their inventive genius and have looked on the patent office as almost as sacred as the Constitution. It has long been apparent, however, that there is need of, and room for, much improvement. At present it is necessary to try out a patent in the Courts before it is regarded as having stability, in the face of the fact that a patent at least purports to be a guarantee by the Government of protection to the holder. There is no special patent court of appeals, though one is now proposed, and suits brought in different Federal courts at times lead to conflicting decisions. The United States Supreme Court is too busy to consider many appeals. The result is that one who devises and markets a valuable invention is sure to face long and expensive litigation where the money available for fighting is at least as important as the merits of the case. In the meantime users of the device are exposed to the peril of unknown and punitive royalties against which the 'guarantee' of the manufacturing company is often inadequate, for the excellent reason that it is ordinarily a limited liability corporation. These various difficulties are grave, the more so since many of them are unnecessary. In Germany, for example, the examination before a patent is issued is so thorough, including notice to all possible contestants, that practically the Government stands back of every patent issued, and contests for infringement are rare. So excellent are the German laws in this regard that some wise American patentees take out German patents merely to get the benefit of the examination. In Australia it has been recently proposed that a single patent shall cover improvements as well as the original invention, and that a man must not declare another production to be an infringement unless he justifies his assertion at once by taking legal action; otherwise the person reflected upon may claim damages and get them without other proof. These are only a few of the controverted questions regarding patents. It is said there are over 250,000 inventors in the United States alone. Certainly they number up into the thousands, and by united action they should be able to focus public opinion on the faults of our present system and formulate proper remedies. Good work already has been done in insisting on a sufficient increase in the force of examiners to bring the work up to date and in preserving the models it was proposed to destroy. Other equally important matters may be readily taken care of by a little effort. Mark Twain's Connecticut Yankee, who did so much to make King Arthur's court interesting to other than lady-like readers of Tennyson, established a Patent Office early in his administration. In that our best loved philosopher recognized that the desire to invent is fundamental to progress.

The Geological Society.

The Cordilleran section of the Geological Society of America held its eleventh annual session at the University of California last week. There was a good attendance and much interest. Among other papers were those of Mr. J. C. Branner on the work of white ants (which it seems are not ants at all) in tropical countries, and the origin of some peculiar modern limestone deposits in central Brazil. Earthquakes in relation to fault-planes formed the subject of a careful analysis by Mr. H. O. Wood, while Mr. Willard Johnson showed excellent pictures of topographic effects due to recent displacement in Owen's Valley. Mr. J. A. Burgess and Mr. A. S. Eakle described the chlorides, iodides, and bromides of silver found in the Tonopah mine. These rare forms are believed to have been secondarily derived from original silver sulphide through the action of descending brines concentrated by evaporation of the waters in which the overlying Siebert lake beds were laid down. Mr. E. W. Hilgard recalled studies made forty years ago of mud lumps at the mouth of the Mississippi, and showed their bearing on the mud-blister which is now interfering with the open passage so long maintained by the Ead's jetties. Mr. J. C. Merriam gave an account of excavations in the Rancho La Brea beds at Los Angeles and of the animals which met death in the sticky asphalt. His paper illustrated how even the dry bones of paleontology may be made alive when the subject is handled by a master who has also a bit of humor. The paleontologists were prominent at the meeting and held a separate session Saturday morning. Paleontology has long received marked attention in California. If we remember correctly it was a paleontological investigation which precipitated the original row upon the Stanislaus. At Berkeley, however, no "chunks of red sandstone" were thrown; nothing in fact harder than certain specific and generic names.

The Cordilleran Section of the Geological Society of America was organized in 1899 and has proved a vigorous branch of the parent Society. The latter was organized in 1888 and includes as fellows nearly all the professional geologists of the United States, Canada, and Mexico. At that the Society is still sufficiently small for most of its members to be personally acquainted, and it has been an effective agency for promoting and criticising geological investigations. The management of the Society has been uniformly good. Two meetings a year are held, a library is maintained, an annual volume of bulletins is printed in excellent shape, and yet, with low dues, a substantial surplus has been built up and securely invested. The Cordilleran is the only local section yet organized. A Mississippi Valley section has been discussed, however, and in a territory so large as America, local branches are sure to prove necessary as well as useful. In the meantime, to serve the needs of specialists in paleontology, a separate but affiliated society has been organized, the president serving as vice-president of the parent body. Some of the larger engineering and professional societies might study with profit the conduct of the Geological Society of America.

BY THE WAY.

Edmund Halley, says Mr. G. F. Becker in a recent number of *Science*, was a very great man. He was not only the first to predict correctly the return of a comet, that which is now known by his name, but also—before Newton had announced his results to anyone—arrived at the conclusion that the attraction of gravity probably varied inversely as the square of the distance. While these and other important achievements of his are well known, it seems to have been forgotten that Halley devised a method of determining the age of the ocean from chemical denudation. Halley recognized that the method as he proposed it was almost impracticable, but writing as he did twenty-eight years before Lavoisier's birth, he could hardly have guessed that accurate analyses of river waters, whose solvent action he so clearly describes, would ever become not merely possible but easy. It is very interesting to note that Halley's reasoning is strictly 'uniformatarian' while he recognized the tendency involved to a maximum estimate. Subject to this same limitation (extended to other features besides an original saltness of the sea), Mr. J. Joly's method of determining the rate at which the accumulation of salt in the ocean takes place from the analysis of river waters is perhaps the most important means now available for an estimate of the antiquity of the stratified rocks, because it is the simplest and least open to question. A great amount of work has been done of late years on the composition of river waters, much of it incited by Mr. Joly's memoir and undertaken with the purpose of improving the data for such a determination of the age of the ocean. Within a few months it will be practicable to make known the results of a revised estimate founded upon data far more ample than those at the disposition of Mr. Joly eleven years ago. Mr. F. W. Clark is now engaged in preparing this estimate. Halley's paper 'On the Cause of the Saltness of the Ocean, and of the Several Lakes that emit no Rivers; with a Proposal, by means thereof, to discover the Age of the World', is briefly abstracted below:

"There have been many attempts made, and proposals offered, to ascertain from the appearance of nature, what may have been the antiquity of this globe of earth; on which, by the evidence of sacred writ, mankind has dwelt about 6000 years; or according to the Septuagint above 7000. . . . This inquiry seeming to me well to deserve consideration, and worthy the thoughts of the Royal Society, I shall take leave to propose an expedient for determining the age of the world by a medium, as I take it, wholly new, and which in my opinion seems to promise success, though the event cannot be judged of till after a long period of time; submitting the same to their better judgment. What suggested this notion was an observation I had made, that all the lakes in the world, properly so called, are found to be salt, some more, some less than the ocean, which in the present case may also be esteemed a lake; since by that term I mean such standing waters as perpetually receive rivers running into them, and have no exit or evacuation. Now I conceive that as all these lakes receive rivers, and have no exit or discharge, so it will be necessary that their waters rise and cover the land, until such time as their surfaces are sufficiently extended, so as to exhale in vapor that water which is poured in by the rivers; and consequently that lakes must be larger or smaller, according to the quantity of the fresh they receive. But the vapors thus exhaled are perfectly fresh; so that the saline particles brought in by the rivers remain behind, while the fresh evaporates; and hence it is evident that the salt in the lakes will be continually augmented, and the water grow salter and salter. Now if this be the true reason of the saltness of these lakes, it is not improbable but that the ocean itself is become salt from the same cause, and we are thereby furnished with an argument for estimating the duration of all things, from an observation of the increment of saltness in their waters. For if it be observed what quantity of salt is at present contained in a certain weight of the water, of the Caspian Sea, for example, taken at a certain place, in the driest weather; and after some centuries or years the same weight of water, taken in the same place, and under the same circumstances, be found to contain a sensibly greater quantity of salt than at the time of the first experiment, we may by the rule of proportion, make an estimate of the whole time wherein the water would acquire its present degree of saltness. And this argument would be the more conclusive, if by a like experiment a similar increase in the saltness of the ocean should be observed: for that, after the same manner as aforesaid, receives innumerable rivers, all of which deposit saline particles therein; and are again supplied by the vapors of the ocean, which rise from it in atoms of pure water, without the least admixture of salt. But the rivers in their long passage over the earth imbibe some of its saline particles, though in so small a quantity as not to be perceived, unless in these their depositories after a long tract of time. And if, on repeating the experiment, after another equal number of ages, it shall be found that the saltness is further increased with the same increment as before, then what is now proposed as hypothetical, would appear little less than demonstrative. But since this argument can be of no use to ourselves, it requiring very great intervals of time to come to our conclusion, it were to be wished that the ancient Greek and Latin authors had delivered down to us the degree of the saltness of the sea, as it was about 2000 years ago; for then it cannot be doubted but that the difference between what is now found and what then was, would become very sensible. I recommend it therefore to the society, as opportunity shall offer, to procure the experiments to be made of the present degree of saltness of the ocean, and of as many of these lakes as can be come at, that they may stand upon record.

"If it be objected that the water of the ocean, and perhaps of some of these lakes, might at the first beginning of things, in some measure contain salt, so as to disturb the proportionality of the increase of saltness in them, I will not dispute it; but shall observe that such a supposition would by so much contract the age of the world."

Geology Applied to Mining.

By T. A. Rickard.

*Mining is an ancient industry; geology is a young science. Man had hardly ceased to be cousin to the ape and tiger when he began to dig the ore from which to obtain the metal required to fashion his primitive implements. But, human beings had developed all the essentials of that complex mode of life we term civilization before the search for minerals was aided by accurate knowledge.

Geology was cradled in Lyell's 'Principles', first published in 1830. Lyell gave form and substance to an earlier recognition by Hutton, that the present is the key to the past, that the unknown can only be deciphered in terms of the known, that the earth is "her own interpreter" to those willing to study the testimony of the rocks. Thus Lyell gave a great impetus to the systematic study of geology; he did more, he gave powerful aid to the establishment of the central doctrine of evolution, as enunciated by Darwin, Spencer, and Huxley. From that time geology became something more than a hobby for amateurs, it became an integral part of natural philosophy. But as developed in England the young science was mainly concerned with stratigraphy and palæontology; as yet its economic function was not realized, except in a few beginnings of investigation into the nature of ore deposits, by De la Beche, Henwood, Fox, and Phillips.[1]

In Germany, Werner laid a foundation for genetic principles and advocated ideas that influenced an entire generation of observers. He held that mineral veins, no less than dikes of eruptive rock, were the result of chemical precipitation from the ocean. Thus he was as extravagant on one side as Hutton was on the other, for the latter regarded both kinds of veins, that is, lodes and dikes, as due to the introduction of igneous material. Hutton and Werner each grasped a truth and halved it by a generalization. Werner's theory was made known in 1791, the English translation appearing in 1809. Fifty years later Von Cotta published a treatise summarizing the theories of the Freiberg school, based upon the observations of the Erzgebirge. He emphasized unduly the importance of the fissure-vein as a type of ore deposit, and thereby became godfather to many narrow conceptions of ore deposition. In 1878 Von Groddeck recognized numerous types and broadened the fundamental principles.

Another wave of scientific interest in the subject was created by the publication, in 1882, of Sandberger's thesis advocating the theory known as 'lateral secretion'. At the close of his essay he stated: "Those who desire to refute the leaching theory will find it necessary, after providing for purer material, to carry out chemical investigations extending over years. Nothing is to be gained by objections not resting upon chemical facts." Thus the chemical study of ore deposits was accentuated, as against the physical and structural. Sandberger imputed the ore in veins to the results of leaching from the immediately encasing rock. His views were narrow; they were combated successfully by Stelzner and Posepny.

The study of ore deposits for a hundred years owed its progress to German research. In England the detection of fossils and the correlation of strata absorbed the attention of geologists to the exclusion of investigation into the nature of the mineral aggregates that are the object of mining. Indeed, not only did geology give the cold shoulder to mining but when geologists condescended to be interested in mineral deposits, they made blunders highly perplexing even to those willing to accept scientific aid. Thus Murchison rashly enunciated the generalization that the Silurian rocks were particularly favorable to gold veins, basing this broad statement on his knowledge of the Ural region; and when gold was discovered in Australia in slate and sandstone of Silurian age, he congratulated himself on the confirmation of his dictum. Later, he interpreted the scanty data at his disposal as warranting "the inference that deep mining in the solid quartz rock is usually unprofitable." No wonder the miner looked askance at the geologist, so that there was a lack of co-operation between the young science and the venerable industry. Moreover, the idea obtained in England that geology stooped to commercialism when she concerned herself with mining.

The notion long persisted that science suffered by becoming utilitarian; the geologist deemed hunting for fossils more becoming than the search for ore; and this tradition in effect prevented English geologists from attempting to unravel the complexities of ore occurrence. A notable example is afforded by the Geological Society. This organization was founded by the fathers of modern geology, and in its records will be found the presentation of the principles that constitute the very foundations of the science to which the Society is dedicated. Yet the sum total of information concerning ore deposits to be found in the journals of the Geological Society is negligible. Englishmen as geologists occupy a position second to none; as contributors to the study of ore deposits they are nowhere. And this result is not due to the want of subjects for investigation nor to the lack of an important mineral industry, for in the last hundred years the mining districts of Great Britain and Ireland have afforded plenty of opportunity and adequate incentive for the economic application of geology. No; I impute the poverty of result entirely to the fact that men of culture have deemed it undignified to make commercial use of scientific knowledge. Only within the last ten years have we been able to point to useful work in this branch of science by Englishmen, among whom I may name Hatch, Gregory, Halse, and Maclaren.

Thus Englishmen founded geology and Germans started the systematic study of ore deposits; but it was in America that economic geology won proper recognition. To the United States Geological Survey we owe much pioneer work in this department of human knowledge. From its inception under Clarence King, in 1879, the Survey has given the warm

*The Le Neve Foster Memorial Lecture, delivered at the Royal School of Mines, London, on March 4, 1910.

[1]De la Beche contributed some excellent observations on the tin lodes of Cornwall; so did Le Neve Foster and Richard Pearce.

grasp of friendship to the miner; and during the last thirty years the scientific men of the Survey have contributed an entire literature on the systematic study of ores and metals as found in nature. In monographs, reports, and bulletins innumerable, the officers of the United States Geological Survey have published detailed descriptions and profoundly suggestive conclusions covering most of the mining districts developed within the wide borders of the American continent. The area involved and the diversity of conditions illustrated have been such as to check narrow views; on the contrary, the variety of ore occurrence has afforded a liberal education to the American geologist, and he has used his opportunity with untiring industry and consummate skill.

Another factor helping the development of this intensely practical branch of geology was the American Institute of Mining Engineers, a society directed by Rossiter W. Raymond, himself a mining geologist of wide experience and a speaker of rare versatility, who did much to bring together official geologists and mining practitioners, so that the meetings of the Institute afforded excellent facilities for the free exchange of ideas on a subject interesting alike to the geologist and to the engineer. The Transactions of the Institute became a valuable library of economic geology, and to it the leaders of thought were prompted to contribute their mature convictions.

Thus at three particular periods, in 1886, 1893, and 1900, a general discussion was incited in America by the publication of papers embodying the new ideas formulated by geologists of international reputation. In 1884 S. F. Emmons published his monograph on Leadville; this voluminous treatise on a rich and famous mining district was issued by the Geological Survey; it was an exceptionally successful effort to unravel the underground structure of a region complicated by many faults, and it gave information of immediate use to those in charge of mining operations. This monograph was a superb vindication of the value of geology in mining. The evidence gathered by Emmons led to much fruitful discussion in the Transactions of the American Institute, and in 1893 prompted Posepny to contribute a treatise based largely on his own study of the Pzribram mines and those of Transylvania. Up to that time the theories of Sandberger had in various guise found favor among mining geologists, that is, the conception of ore deposits as being derived from the wall-rocks of veins by means of the solvent action of waters moving laterally. To this interpretation of the facts disclosed by mining, Posepny opposed systematic observations the effect of which was to elucidate the basic idea that neither the lateral, the ascending nor the descending waters were to be credited with the work of ore deposition—not any one of these phases of the circulation, but the whole of it, as modified by varying conditions at successive periods.

So far, progressive knowledge had come mainly by induction from facts, but an exceptional development of scientific enquiry was illustrated in 1900 when Van Hise contributed a brilliant essay, which was essentially a deductive reasoning from physical and chemical principles. His suggestions proved illuminating along new lines of thought and stimulated fresh investigation. He took the underground circulation of water as one connected manifestation of natural energy, and from a comprehensive review of the literature then available he emphasized two conclusions: (1) sulphide ore is generally deposited by ascending water; (2) secondary enrichment is effected by descending water. Simultaneously with this pronouncement concerning the origin of the richer parts of lodes, Emmons and Weed published papers explaining how copper deposits became enriched at moderate depth by precipitation of the metal leached from near the surface by descending waters. From lodes of copper the idea of secondary enrichment was applied to deposits of other metals, so that the formation of bonanzas in general became better understood. This, of course, was a great step forward, for it gave the miner a clue to the discovery of rich ore, which is the main object of his search.

Thus, at last, geology in relation to mining reached a point where the most uncompromising utilitarian could not refuse to recognize its commercial value. Starting as the science of amateurs, geology in its economic phase had become the technology of money-makers. And was it debased thereby? Rather let us say that the science was now ennobled by giving help to those who labor in the mine and quarry; from the heights of philosophy, geology had stooped to be of service to humanity, and by so stooping had herself been raised to greater honor.

Before summarizing the conclusions now deemed worthy of acceptation, it is necessary to refer to two of the latest ideas concerning the genesis of ore deposits. While the American geologists were occupied in analyzing the effect of water action, a Norwegian investigator, Vogt, was making a careful enquiry into the differentiation of magma—the molten matrix, which, on cooling, becomes the substance of rock. Vogt came to the conclusion that the normal terrestrial water-circulation underground played only a minor part in the primary origin of ore deposits, however much that water-circulation may have effected the later concentration of ore from such portions of the magma as were rich in metals. Kemp applied this idea and showed how the greater number of deposits containing gold, silver, and copper ores, are near igneous rocks, with which he believed them to be genetically connected. Meanwhile, Spurr had become impressed with the evidence of segregation in gold veins, and announced a radical departure from accepted theory by describing the gold-bearing quartz veins of the Yukon as representing the last stage of magmatic segregation. Thus quartz veins are held to be the silicious product of a process that in its final phase is marked by a magma so attenuated as to resemble heated water charged with silica and other mineral matter, including gold. This theory led to researches into the physical effects of metamorphism at the contact of igneous with sedimentary rocks, and yielded evidence of the mineralogic changes induced by intense thermal action. It was shown, by Lindgren, Kemp, and Weed, that the sedimentary strata are made porous by metamorphism, which may be compared in its effects to the results produced by burning a clay into a brick. The derivation of ore from magma and the activity

imparted to the underground water-circulation by vulcanism were new ideas highly suggestive to geologists and pointed to fresh lines of observation.

Thus attention was directed to the igneous rocks as agents in ore deposition and stress was laid on the part played by magmatic waters as against the exclusive agency of meteoric waters, that is, the water originating at surface from rainfall. In 1903 an attempt was made to apply these new ideas in the classification of ore deposits according to their genesis, whereupon a lively debate ensued before the Geological Society of Washington. This discussion was inconclusive, as might be expected, for we do not know enough concerning the origin of ore deposits to warrant any final classification. But the attempt exhibits the dark places in our knowledge and serves to distinguish between what we know and what we think we know. Thus science progresses.

This discussion concerning the parts to be allotted, on the one hand, to igneous rocks and the magmatic waters associated with them, and, on the other hand, to the meteoric waters and the vadose circulation, led to a clear appreciation of the importance of an ore-forming agency hitherto not recognized by economic geologists. In successful opposition to Posepny, Van Hise, and other authorities, it fell to Kemp to turn the whole trend of speculation and to demonstrate that magmatic waters must be the carriers of the metallic compounds constituting ore deposits. His essay, entitled 'The Rôle of the Igneous Rocks', published in 1901, drew attention to the dryness of deep mines, "the general absence of water in the rocks below moderate depths, except in regions of expiring vulcanism," and the distribution of mining districts as related to the distribution of igneous rocks. Attention was drawn thereby to the 'water-level' in mines and the state of diffusion of water in rocks. In 1900, in 1904, and again in 1908, I directed attention to the significance of the evidence afforded by deep mining. Usually when the earth's exterior is penetrated by a shaft the ground is dry until at a shallow depth, varying from 50 to 300 feet, water is struck.[2] Other shafts in the vicinity will fill with water at about the same depth, so that a 'water-level' becomes recognized. Below this level the water entering a shaft or a pit increases in volume until a maximum is reached at six or seven hundred feet. On resumption of sinking, if the water entering the shaft be collected and pumped to the surface, the influx of additional water decreases until at 1000 ft. or thereabouts, the ground appears to be dry, that is, no water is visible, although the dusty rock will be found on analysis to contain 3% water. This is the general experience of mining all over the world; local variations, due to seasonal changes and rock structure, are observed, but they only serve to emphasize the general conclusion that vertical openings into the earth's crust do penetrate below the reservoir or accumulated store of the water fed by rainfall. In effect, we have a 'water-zone', as against the universal ground-water formerly assumed to exist to an indefinite depth; for example, Van Hise mentions 10,000 metres as the limit and he actually speaks of "the sea of ground-water." Others have set even less definite bounds to the extension of the water that is supposed to saturate the rocks in which deposits of ore are formed.

Obviously, the distribution of water is a vital factor in the processes by which ore is deposited in lodes and veins. To the miner, whose operations are restricted, the belt of ground-water will appear as a zone relatively deep; to the geologist, who views the matter on a larger scale, the zone will appear as a blanket, the top of which is smooth, while the bottom is extremely irregular. Under the water-zone is a region of dry rock, and somewhere below it, at a variable depth, is the source of the magmatic water, the final product of differentiation and the result of chemical changes within the earth. This magmatic water does not rise by reason of gravitative stress nor is it connected with the ground-water; there is a hiatus between the source of the magmatic water and the reservoir of meteoric water; so that the older conception of rain falling upon and into the earth at one place and circulating downward until induced, by heat and pressure, to ascend at another place, is now no longer tenable, save in a limited sense. We have a blanket of cold meteoric water, then a region of dry rock, penetrated by fractures, which give passage to the deeper upwelling thermal waters of magmatic origin. From the surface the meteoric waters descend and accumulate at the water-zone, to be returned to the surface in the form of springs and artesian flows. The hot magmatic waters ascend through fractures made by movements due to volcanic action and through fissures caused by readjustments of the earth's exterior, until they reach the upper, almost superficial, zone of cold water.

Geologists have assumed that the mineral-carrying waters from the depths can pass through rocks saturated with water without losing their identity, that is, they have failed to recognize a fundamental factor in the problem of ore deposition. We might as well imagine a mountain stream entering a morass, passing through the morass, and issuing at the lower end without change of character. Indeed, the water-zone has many points of similarity to a morass, for it is a tract wherein both reducing and oxidizing conditions variously prevail, owing to the presence of organic matter on the one hand and of entrained oxygen on the other. Thus it is apparent that the work of the miner has yielded information of the greatest significance in any theory of ore deposits; in short, inductive inference from facts serves to discipline deductive reasoning from scientific principles.

(To be Continued.)

[2] Of course, these figures are given mainly for the purpose of illustrating facts, and of elucidating the idea based upon them. The ground-water may be struck at grass-roots, as in seasons of excessive rainfall, and it may not be reached for a depth of 500 ft., as in the arid tracts of Arizona. On the other hand, the bottom of ground-water may exist anywhere from 500 to 2500 ft., according to the climate, the rock-structure, and the fissured character of the ground. Moreover, I am dealing with igneous and metamorphosed rock-masses; in sedimentary strata the bedding planes will regulate the descent of water, so that the water-zone is difficult to recognize in coal mines. By omitting figures and confining myself to glittering generalities, it would be easy to escape criticism; but I am willing to risk criticism, hoping to clarify a fundamental conception governing the distribution of ground-water.

Kimberly, Nevada.

Written for the Mining and Scientific Press
By Jay A. Carpenter.

The mining camp of Kimberly which has sprung into prominence in the last few months, is in the Battle Mountain district. This district is receiving considerable attention on account of favorable showings of copper, lead, gold, and silver ores, the result of development work carried on consistently for many years. The presence of iron ores and limestone in addition to the copper ores offers favorable conditions for smelting. There have been small but

Kimberly, Nevada.

steady shipments of carload lots of gold and silver ores to the Utah and California smelters. However, it remained for the discovery of Bannock with its rich free-gold ores on the very surface to attract marked attention to the district. Bannock has settled down to solving the question of the depth and nature of its ore deposits, and attention is now centering upon the camp of Kimberly.

Kimberly is 18 miles southeast of Battle Mountain, 10 miles of this distance being over valley road and the last 8 being a steady climb up a winding canyon. The camp, consisting of several large frame buildings, cottages, and tent-houses, lies at the intersection of two gulches at an elevation of 6500 ft., while the mine workings are along the crest of the ridge to the west, and 300 to 400 ft. higher. For years the few prospectors' huts at this convenient watering place on the country road were known as Marble City. An abandoned stone hut and a 40-ft. inclined shaft dates back of the memory of any local resident, perhaps back to the days when the wealth of Austin allured the prospector to the mountains of Lander county, for the ore in the incline shows a high lead-content and a high ratio of gold to silver, while the free-gold surface-showings were evidently undiscovered. In 1907 prospectors encouraged by the surface 'pannings', discovered wire-gold in places not over 300 ft. from the old shaft. Other discoveries along the crest followed, and in 1908 the camp had a lively boom, being known as Hilltop. Although 1908 was a dull year, the control of the stock in the two main companies was quickly placed under option at fancy figures. On both properties development was limited to the main discoveries. On the Hilltop property a large open-cut was made in following the gold stringers, and exceedingly rich ore was shipped in small lots. A tunnel at a depth of 70 ft. failed to find rich ore, and the option was dropped. On the Independence claim of the Philadelphia Western Mining Co.'s ground an incline shaft following the vein was sunk 180 ft., connecting with a 265-ft. tunnel. From this work about $15,000 in rich shipping-ore was taken from one lease. However, the promoters lost their option through holding for too high a figure. These failures caused the camp to recede from public notice.

The owners, able to keep but a few miners at work, divided their ground into lease-blocks, and many of the men went from day's pay to leasing, attracted by the surface-showings. When a miner can guide his work by a few minutes with mortar, pestle, and pan, and a few encouraging colors are found, his energy is unrelenting and his faith unbounded. It is the showing made by these lessees that has brought the camp again to public notice. They have found high-grade ore in several leases on the two main properties and on a claim 1500 ft. to the west, and they claim to have opened large quantities of milling ore. Already the control of the Hilltop and Independence groups of claims, and the Golden Rule claim to the west, have been contracted under option to one group of capitalists, who are now rushing the construction of a 20-stamp mill, and are building wagon-roads to the dumps and working places. The mill-site is a half mile west of the town in a gulch between the Hilltop ridge and the Golden Rule claim. Water for milling is to be obtained by pumping from Indian creek some 3000 ft. down the gulch. The 20 stamps

Main Workings on ndependence Claim.

are to be followed by amalgamating plates, and concentrating tables. The ore will readily yield 90% by this treatment, over 80% being obtained by amalgamation. Cyanidation of the tailing will hardly be attempted on account of the probable low value and a small copper content. The building of the mill and the short life left to the leases have stimulated work, and the camp has a thriving appearance.

The general geology of the district is that of prominent ridges of quartzites and silicious shales, much faulted and irregular in strike and dip. The general strike is north and south and the dip 45° or greater

to the west. The quartzite occurs both as an easily fractured light-colored variety, and a very massive, dark variety. The quartzite is formed of corroded quartz grains which have been largely replaced by a mixture of secondary quartz and sericite. The quartzite has evidently been subjected to considerable metamorphism since its formation. On the Hilltop ridge are wide dikes of an altered andesite, having about the same strike but less dip than the quartzite. This material is so badly weathered that it is only in some of the fresher specimens that a few of the lime-soda feldspars remain sufficiently unaltered to be recognized. The other original minerals have disappeared. At present the feldspars are replaced by sericite and kaolin while pyrite and quartz make up the remainder of the rock. A diorite porphyry also outcrops at the east base of the ridge, and can be traced through the camp and a half mile to the eastward. This diorite is a fresh looking rock, though altered. It contains large porphyritic crystals of andesine. Outlines of mica and hornblende remain, but the original minerals have been entirely replaced by chlorite, magnetite, and calcite. Tourmaline crystals are present and this unusual association may indicate a slight amount of contact-metamorphism. At some distance from the camp are prominent ridges and masses of granite. At the south end of one of these ridges, 3½ miles to the east of the camp, is the Grey Eagle mine, an old lead-producer.

Four miles to the west, on the north flank of Blue Dick, a prominent peak, is the quartzite ridge from which the Dean mine extracted a large amount of milling ore through a period of years. On an intermediate ridge is the Maysfield property, an old producer. On the Hilltop ridge the quartzite is also the ore-bearing formation. The ore of the camp in general is fractured quartzite, cemented with quartz, and carrying free gold. The veins or orebodies as a rule are rather sharply defined from the quartzite, but are irregular in width and course, the course being in general parallel to the bedding plane of the quartzite. The wide dikes of the andesite are barren except for a small but constant gold content. The only appearance of the andesite in connection with the ore is in the form of tongues in the veins.

There are interesting variations from this general description. On the Hilltop open-cut the gold occurs in a coarse state, directly in the dark brown quartzite, with little or no apparent vein-formation. At times well crystallized covellite is found associated with the gold. On one of the leases on the Independence group is the odd occurrence of minute leaf gold and tourquoise lying together on the fracture faces of the quartzite. On the main workings of the Independence claim lead minerals are closely associated with the ore, occurring both as cerussite and galena. The cerussite is well disseminated through the ore, while the galena is segregated. The richest gold seams lie next to the galena, but not in the galena itself. As a whole the district is interesting, and the advent of capital for deeper development will give the mines a fair trial. The rock determinations for this article were made by J. C. Jones, assistant professor of mineralogy in the Mackay School of Mines, at Reno, Nevada.

Diaphragm Cones and Tube-Milling.

Written for the MINING AND SCIENTIFIC PRESS
By WALTER NEAL.

Numerous references have recently been made to the invention of W. A. Caldecott known as a 'diaphragm cone'. As all of these have referred to work done on the other side of the world, a brief description of the apparatus as used in the mills of the Cia. Minera Las Dos Estrellas, and some experiments made with it as a thickener before tube-milling, will be of interest.

The apparatus is described by its inventor as a "classifier of the conical type * * * kept filled

Fig. 1. Filter Cone.

nearly to the top with sand, and an essential patented feature of its successful operation consists of an internal serrated or notched horizontal disc-diaphragm near the bottom."*

As used at Dos Estrellas it consists of a circular sheet-iron plate, supported toward the apex of an ordinary cone-classifier by two straps riveted to the plate, and having their ends riveted to the sides of the cone, leaving an annular space between the plate and the sides. The width of this annular space, and the height of the diaphragm above the apex of the cone, vary with the size of the cone and the tonnage and character of the pulp. So far as my experience goes these points are best determined experimentally although with sufficient data, doubtless some approximate formula could be deduced. A cast-iron plug-cock at the apex provides a means for regulating the underflow.

When starting operation this cock is closed, and the pulp is turned into the cone. Sand is allowed to collect until it is within about 10 in. of the overflow. The cock is then opened enough so that thick sand may issue at the same rate that it settles out of the thin pulp flowing into the cone.

The settled sand, on account of its thickness,

**Journal* of the South African Association of Engineers, Dec. '08.

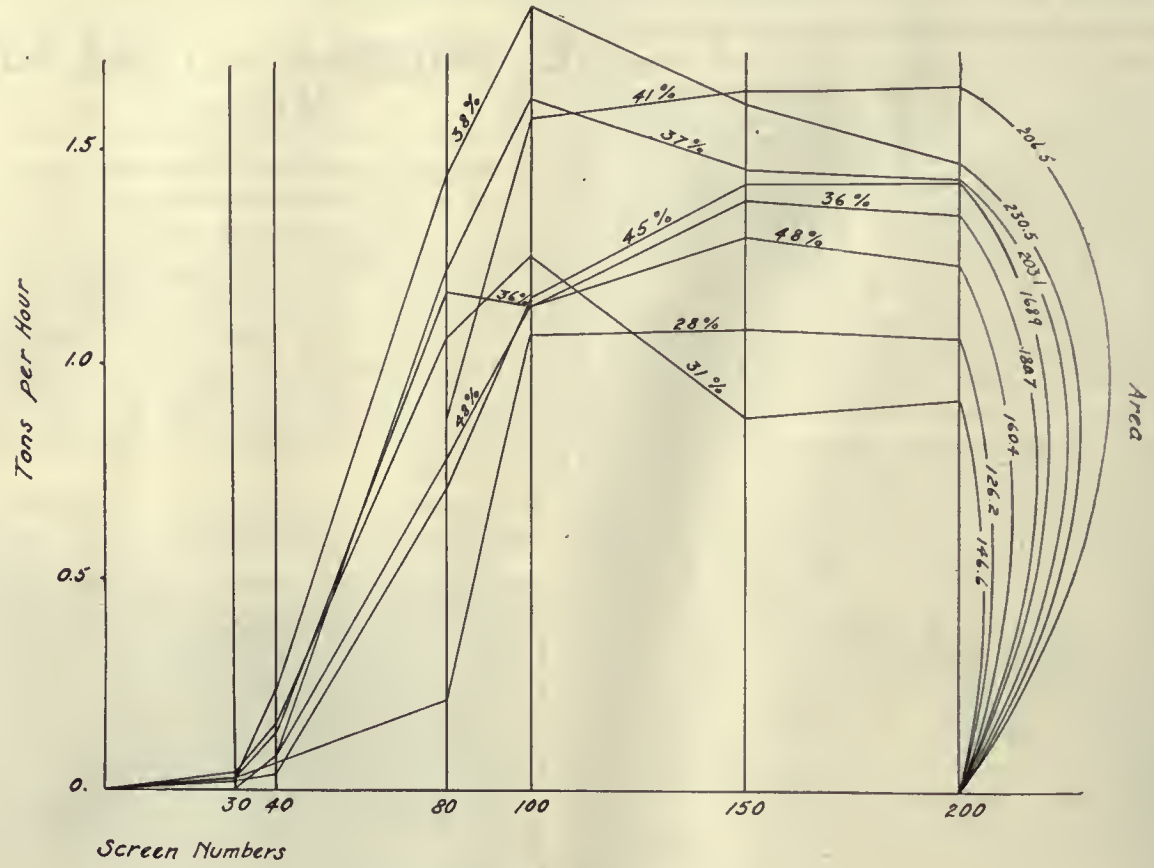

Fig. 2.
Test on Best Thickness of Tube Mill Feed.

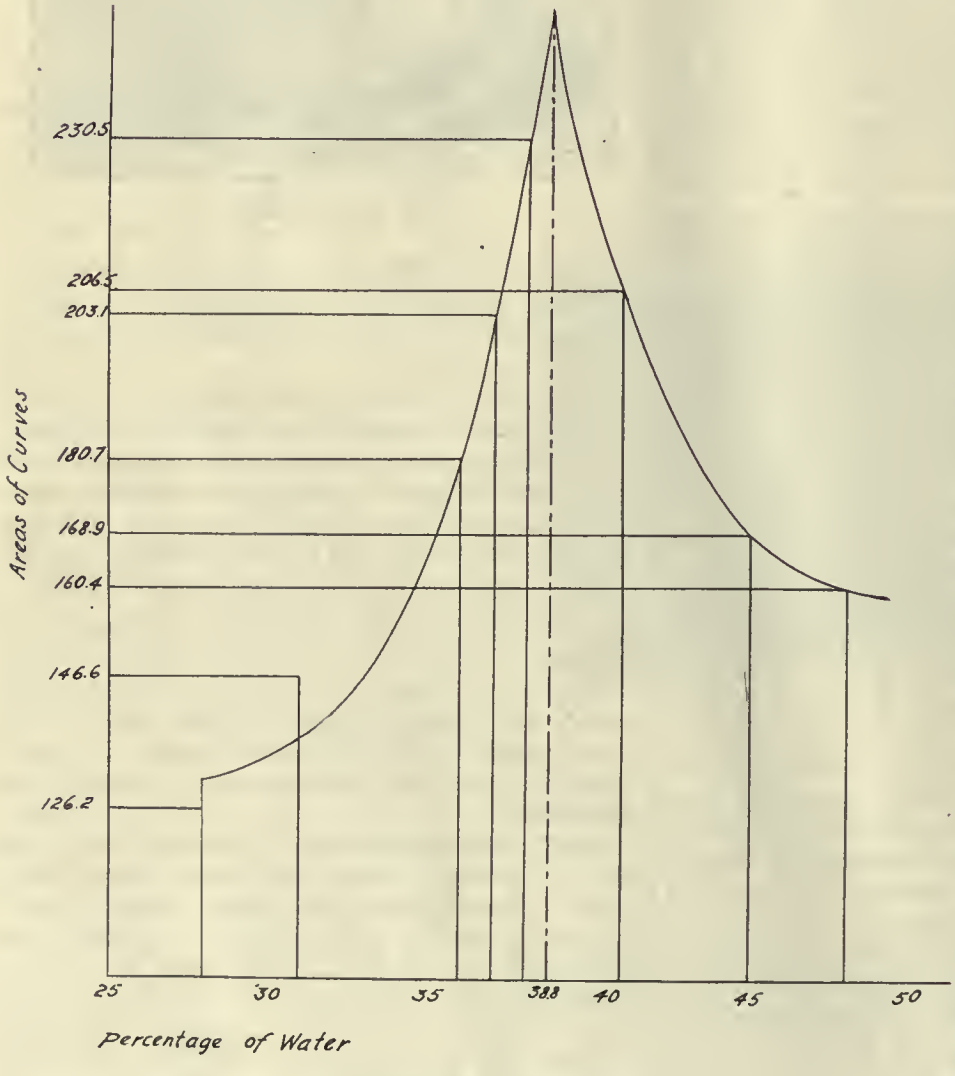

Fig. 3.
Test on Best Dilution of Tube Mill Feed.

issues from the spigot in a stream of low velocity but of large area. The pulp entering the cone above, drops its heavier particles, thus automatically renewing the bed, and the valve at the apex is regulated so that the level of the bed neither rises nor lowers. Should the bed of sand drop too low a break occurs, and thin pulp issues from the spigot, the same as in a simple cone. The remedy is to close the cock and allow the channel to pack with sand again. Should the spigot, on the contrary, not be opened sufficiently, the bed of sand will rise to the rim of the cone and a sandy overflow will result.

It will be seen from the above that the apparatus does its best work on large cones where the level of the bed of sand has sufficient vertical variation to allow for slight fluctuations in the feed, without dropping too low and breaking through, or rising so high as to cause an overflow of sand. A steady feed is, of course, desirable. Where the

fall in a mill is sufficient to allow for the installation of large cones, it is my experience that it is better to allow a sandy overflow which may be passed through a sand-return cone without a diaphragm. On large cones, 9 ft. or more in height, but little trouble is experienced, and with the underflow once properly regulated and a steady feed established, the cone will run for hours, giving a slime-clear underflow and a sand-clear overflow with no attention whatever. Due to the large aperture of the underflow nothing smaller than a gunny sack will stop it up.

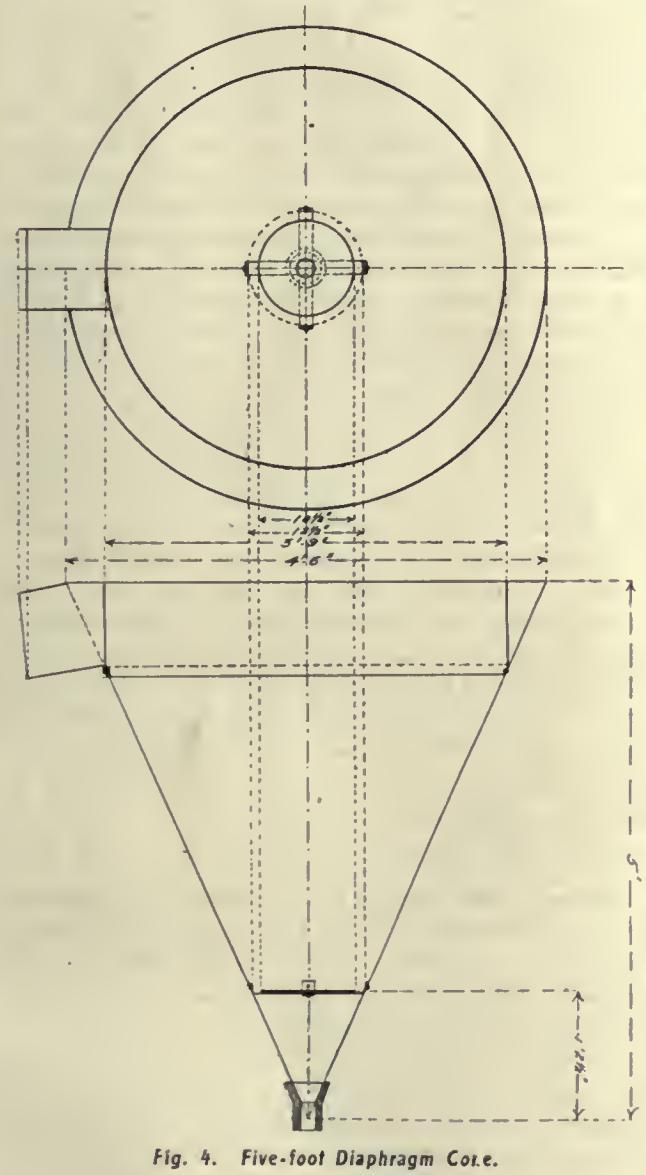

Fig. 4. Five-foot Diaphragm Cone.

The experience at Dos Estrellas has been that the the diaphragm cone does better work when given a heavy feed than when given a light feed. For instance, a tube-mill thickener 8 ft. high by 7 ft. diam., did its best work (without diaphragm) with underflow bushed down to a ½-in. pipe-nipple and receiving 150 tons of ore per day (16 mesh) direct from the batteries, having a dilution of about 9 to 1. The same cone, when fitted with a diaphragm 16 in. above its apex, did its best work when receiving about 250 tons of the same pulp per day. The reason is that the thick sand underflow ran steadier through the larger aperture required for the greater tonnage than through the smaller one. Probably change in the proportions of the diaphragm would improve matters on the smaller tonnage.

The underflow consists of remarkably clean sand. In the case of the cone mentioned above the underflow through the ½-in. nipple carried from 15 to 20% through a 200-mesh screen, whereas the average underflow, after installing the diaphragm, carried from 3 to 5% passing a 200-mesh screen. This is, of course, a great advantage when thickening for tube-milling, since no one likes to pay for power to grind pulp finer than 200 mesh, while coarser sand is actually going into the slime-tanks. The underflow from the diaphragm cones contains from 28 to 30% moisture.

When the diaphragms were first installed at Dos Estrellas great grinding efficiency was anticipated on such extremely thick pulp. The results, however, were disappointing, being no better than had been obtained on pulp with 50 to 55% moisture. Experiments were then started to see where the trouble lay, and as the pulp appeared to be too thick for effieient grinding, to determine at just what dilution the tube-mill would do its best work.

The tube-mill used was of the Gates type, made by the Allis-Chalmers Co., and had an inside diameter of 5 ft., and a length of 24 ft. The effective diameter is reduced about 6 in. by the 'El Oro' liners used. The mill ran at 26 rev. per min. The thick sand from the diaphragm was fed into the mill through a small sheet-iron launder passing from below the cone to the trunnion of the mill. In order to feed the sand at varying degrees of dilution for purposes of experiment, a water hose was laid in the feed-launder, and the required amount of water allowed to run into the mill along with the sand. The mill was allowed to run long enough for conditions to adjust themselves within it, and during the experiments samples were taken at five minute intervals of the heads and tailing. A determination of the tonnage crushed per hour was also made at the middle of each experiment by weighing the amount of wet pulp discharged by the mill in a measured time. Having the specific gravity of the tailing, the dry tonnage crushed per hour could be calculated from this.

Sample	Specific Gravity	Tons per Hour	On 30 mesh	On 40 mesh	On 80 mesh	On 100 mesh	On 150 mesh	On 200 mesh	Through 200 mesh
1N	1.760	4.7	0.5	1.5	12.5	33.5	35.0	1.0	16.0

Table 1.

The results of sizing tests on these samples are shown in Table 1. The figures in Table 2 were obtained by subtracting the total percentage remaining on any mesh in the tailing from the total percentage remaining on the same mesh in the heads. Thus in test No. 1 is obtained for 30-mesh $0.5 - 0 = 0.5$; for the 40-mesh $1.5 + 0.5 - 0.5 = 1.5$; for 80-mesh $0.5 + 1.5 + 12.5 - (0.5 + 9.5) = 4.5$, and so forth. Table 3 was obtained by multiplying the percentages shown in Table 2 by the actual tonnage per hour. It thus shows the actual amount of pulp formerly too coarse to pass through each mesh, but which was made to pass through it during the process of grinding. Table 3 supplies the ordinates for the curves in Fig. 2. The included areas of the curves in Fig. 2 are shown, plotted as ordinates in Fig. 3, as giving some sort of a basis of comparison of crushing efficiency.

Test No.	Percent Water	Tons per Hour	On 30 mesh	On 40 mesh	On 80 mesh	On 100 mesh	On 150 mesh	On 200 mesh
1	28	4.7	0.5	1.5	4.5	22.0	23.0	22.0
2	31	4.6	1.0	3.5	25.0	27.0	18.0	20.0

Table 3.

These tables clearly show the ideal dilution to be in the neighborhood of 39% moisture. It is surprising to note what a marked difference in grinding, a comparatively small difference in dilution makes, and it immediately suggests that not enough attention has been paid to this point in the past. To bring the matter home in another way it may be stated that approximately three tube-mills working on 39% pulp will do the work of four mills working on 36 or 48% pulp.

It is probable that the 'critical dilution' would vary at different plants on account of different ores and various makes of tube-mills, but certainly the matter is worth investigating. Undoubtedly it is more than a coincidence that V. B. Sherrod, experimenting with tube-mills at the Guerrero mill, Real del Monte, finds that "the grinding efficiency increases with the percentage of solids in the feed up to about 55 or 60%."* My acknowledgments are due to A. Quartano for his skill and care in carrying out the experiments herein described.

CACHANI MINES, ECUADOR.

Written for the MINING AND SCIENTIFIC PRESS
By H. P. GORDON.

Some years ago I received, installed, and operated a hydraulic mining plant in Ecuador for an American company. It seems that the farther off and the more inaccessible a mine is the more glamour is attached to it in consequence, an dthe keener some people are to chase after it. This particular mine was a large Government concession. Mark that word 'concession'; it is still used everywhere throughout the Spanish American republics. The mine was one degree north of the equator; had been worked by the Spaniards; previous to that by the Indians; and perhaps some of the gold furnished to Pizarro came from this very place. Golden fish-hooks lost by the Indians and recovered from the rivers, were shown to every visitor who came into the country. All of this was part of the 'glamour' used by promoters. Those fish-hooks could not be bought at any price; they were too valuable for catching another kind of fish.

The Cachani mines were near the coast, at an elevation of about 300 ft. above sea-level. It rained to some extent every day in the year except a so-called 'dry season' of three weeks, when it only rained at night. The gravel lay in bench-deposits formed by the present rivers, and had been nearly worked out by the Spaniards. After a year's time the American company concluded that there was not enough in sight to warrant moving the plant.

Geologic thermometry is now attracting attention and was discussed by Fred E. Wright at the Boston meeting of the Geological Society of America. In ordinary thermometry, temperature is defined by the expansion of a perfect gas, and is expressed in terms of fixed units, determined by the freezing and boiling points of water under standard conditions. Temperatures are ascertained practically by means of thermometers which, although they differ greatly in type, are all based on some property which varies in a definite way with the temperature. In geology temperatures are of fundamental importance, particularly the temperature to which rocks were heated in past geologic ages and under inaccessible conditions. Points on the geologic thermometer scale must, therefore, be historical points, to be determined primarily by the permanent effects which such temperatures have produced on the rocks and rock components, and which are clearly marked even at lower temperatures. The factors which may serve to furnish points of this nature are, especially: melting temperatures of stable minerals and of eutectics, inversion temperatures of minerals, temperature limits beyond which monotropic forms cannot exist under different conditions of pressure, also stability ranges of enantiotropic forms and of minerals which dissociate or decompose at higher temperatures, also temperatures beyond which certain optical or physical properties are changed permanently. These factors can be and are being determined by modern laboratory methods, and are in turn directly applicable to the study of rocks. The data now available on the geologic thermometer scale indicate that the establishment of such a scale is feasible.

Plotting Co-ordinate Surveys.

Written for the MINING AND SCIENTIFIC PRESS
By J. J. BRISTOL.

The device for plotting co-ordinates consists of a 45° triangle graduated (on the two edges at right angles to each other) to any required scale. In the figures are shown triangles graduated so that 1 ft. = 240 and 500 ft. respectively; others are readily available. The graduated edges are about 6 in. long.

By a proper assumption of the distance apart of the co-ordinate lines their representation on the plan will be contained within the graduated edges of the triangle. For example, using the 1 to 240 triangle the co-ordinate lines must be 100 ft. apart, and hence represented on the plan 5 in. apart; the 1 to 250, 100 ft., or $4^4/_5$ in.; the 1 to 500, 200 ft., or $4^4/_5$ in.; the 1 to 2500, 1000 ft., or $4^4/_5$ inches.

In the following discussion the axes of co-ordinates are assumed to be as represented in Fig. 1. Suppose the plotting is required on the horizontal plan

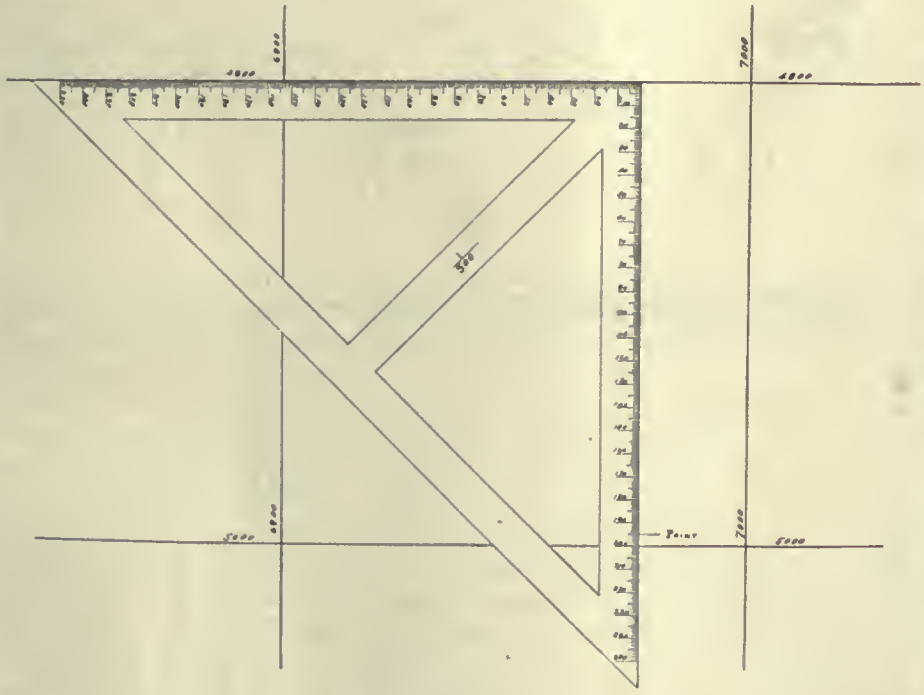

Fig. 2.

(scale 1 ft. = 500 ft.) of the stations whose co-ordinates are

	X.	Y.	Z.
309	6953.30	4995.06	1283.24
310	6978.09	4982.28	1280.64
311	6997.73	4975.30	1281.64
312	7059.39	4959.85	1285.29
310a	6976.75	4969.72	1251.65
310b	6974.15	4961.79	1241.71
310c	6975.36	4955.56	1235.55
210	6963.14	4897.66	1185.99
211	6975.96	4892.15	1185.45
212	7068.83	4866.98	1186.47

To plot Station 309, place the graduated triangle 1 to 500 on the plan (see Fig. 2) with one graduated edge coinciding with the line Y = 4800; then move so that the 153.30 (6953.30 - 6800) division coincides with the line X = 6800; then at the 195.06 (4995.06 - 4800) division on the other edge, prick a point; this will represent on the plan the position of Station 309. The other stations are plotted similarly (see Fig. 3). As a check, place the graduated triangle so that the 195.06 division on one edge coincides with the line Y = 4800, and prick a point at the 153.30

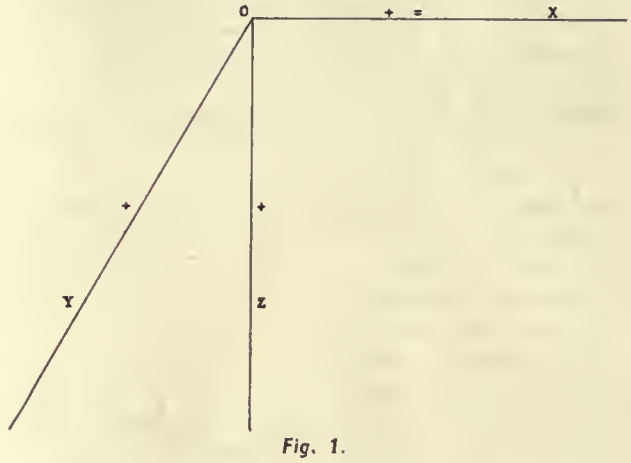

Fig. 1.

division on the other edge. The two points should coincide. On any vertical plane or section the Z ordinate may be plotted similarly.

The graduated triangles above described may be employed in various ways. For example, suppose it is required to transfer the lower drift and part of raise represented in Fig. 4 (scale 1 to 500) to a plan (scale 1 to 240) (see Fig. 5). In Fig. 4 the 1 to 500 triangle is placed as indicated, in this instance with the 160 division on one graduated edge coinciding with the line X = 6800; the Y ordinates (4800 + 189.50) and (4800 + 195.50) of the points of intersection of the contours of the drift with the graduated edge of the triangle are read off: in Fig. 5 the 1 to 240 triangle is placed as indicated with the 60 (160 - 100) division on one edge coinciding with the line X = 6900; then points are pricked at divisions 89.50 (4800 + 189.50 - 4900) and 95.50 (4800 + 195.50 - 4900.) The triangles are moved convenient distances of 5 or 10 ft. and the Y ordinates read off and transferred as before. The points thus indicated are joined showing a contour similar to that of Fig. 4. Again if a projection is required on the vertical plane through Stations 210, 211, of the raise connecting 210 and 211 (see Fig. 3) (scale 1 to 240), then assuming in this plane that 210 is at 0 ft. horizontal distance, the other stations are at horizontal distances (measured off from Fig. 3).

Station.	Feet.	
210	0.00	
310c	59.00	(projection on plane 210, 310)
310b	65.00	" " " " "
310a	73.50	" " " " "
310	86.00	

and for 310 the graduated triangle 1 to 240 is placed with the 86 division on one edge coinciding with the

line Z = 1200, a point pricked at division 80.64 (1280.64 – 1200) (obtained from station co-ordinates listed above) on the other edge. The other stations are plotted similarly. From the notes taken when the transit was set under the several stations the contour is sketched in and the desired section is as shown in Fig. 6.

These triangles save considerable time in plotting,

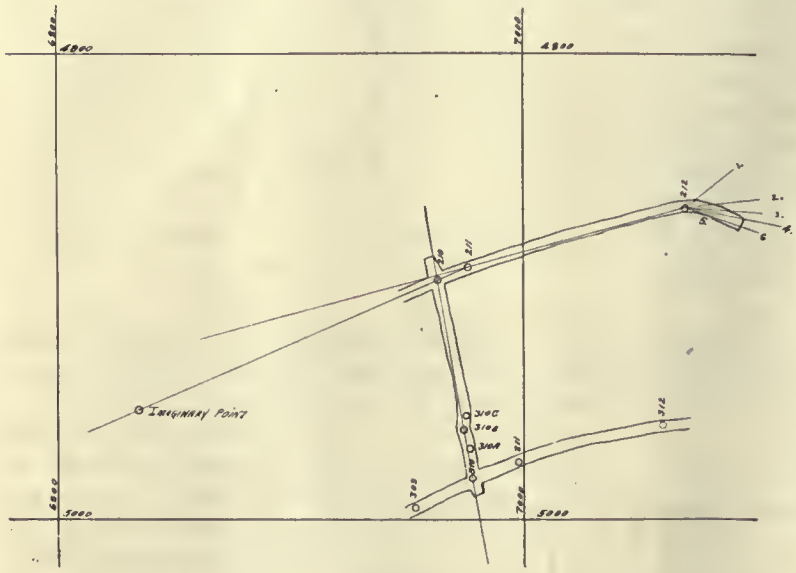

Fig. 3.

are accurate, and do not soil the plans, as there are no erasures to be made.

The device for plotting drifts is represented in Fig. 7. It consists of a protractor about 8 in. diam., graduated to 20 min., and numbered to correspond to those instruments whose numbering of graduations on the horizontal circle is from right to left. *B* is a slot in which *C* can be freely moved. *D* and *E* are scales graduated as desired; in this instance *D* is 1 to 500 and *E* 1 to 240. *F* is a hole in the slide *C* with the centre on the line through the centre *O* of the protractor and 0°. Line *G* passes through *F* and serves to indicate the distance along *D* and *E* of the centre of hole *F* from *O*. *H* is an upright, shown in section at *I*, through which passes vertically a fine needle. This needle is exactly over the centre of the protractor. The application is as follows, supposing the notes for the drift survey are: instrument, under 212; backsight, 211; foresight, drift.

	Horizontal angle.	Slope distance, ft.	Vertical angle.	
1.....	157°20′	4.75	90°	
2.....	188°40′	12.00	90°	
3.....	198°40′	18.00	90°	
4.....	206°40′	26.00	90°	
5.....	213°30′	10.00	90°	
6.....	213°30′	25.00	90°	Offset right 2 ft. Offset left 3 ft.

A line is drawn through 212 and 211 extending beyond 211; the protractor is then placed on the plan; the needle point pressed down through 212, and then revolved until 157°20′ is indicated, the slide moved to indicate 4.75 ft. in this instance on the scale 1 to 500. A mark is then made through the hole in the slide. This mark represents a point in the contour of the drift; similarly for the other points. When point 6 is plotted the off-sets indicated are made and the several points joined, thus showing the outline of the drift (see Fig. 3).

If when using this protractor the two stations are very near together, to secure accuracy the best plan is to find the co-ordinates of an imaginary point in the extension of the line through the two stations before drawing the reference-line through the two stations. For example, suppose the transit were set under 211, with the backsight 210, then proceed as follows:

Station.	X.	Y.
211	6975.96	4892.15
210	6963.14	4897.66
Difference	12.82	–5.51
Multiply by 10.....	10	10
Subtract from	128.20	–55.10

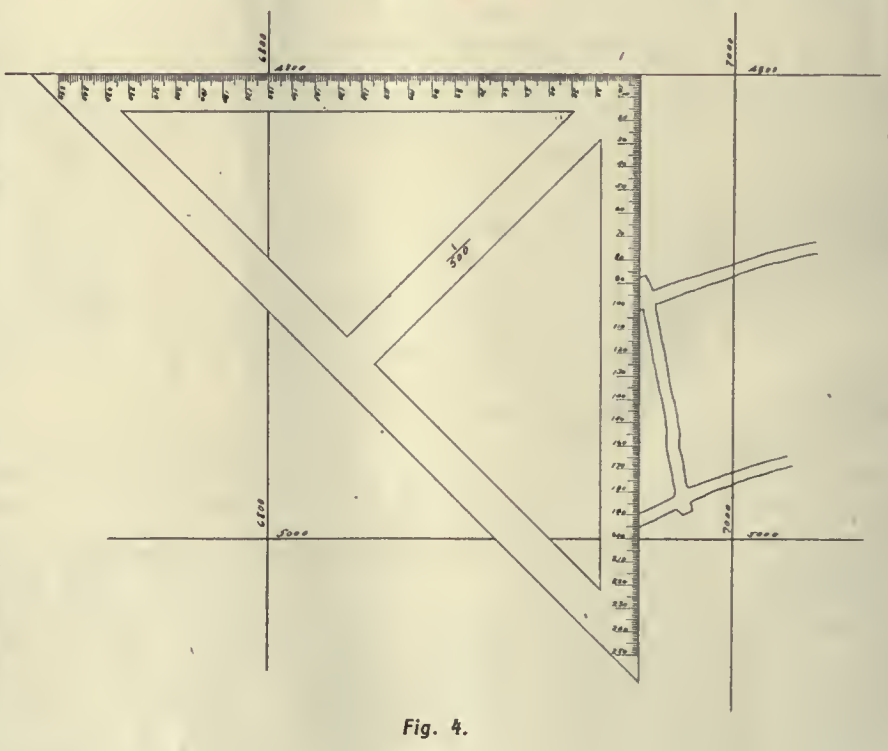

Fig. 4.

210	6963.14	4897.66
Co-ordinates of the imaginary point	6834.94	4962.76

Plot this point (see Fig. 3) and then draw a line through it and 210 or 211. To eliminate erasure as much as possible the line need be drawn for a short distance only, near the edge of the protractor. For distances less than half the length of the slide, that is, less than 2 divisions of 1 to 500 scale or 2 ft.. after the horizontal angle has been indicated, the needle may be removed, and the slide moved to the required distance.

Perhaps a clearer idea regarding the use of the device for plotting stopes (which I prefer to designate the 'plotting protractor') will be given by describing briefly the method of surveying and plotting stopes to which it is applicable. The transit or theodolite is set up under a station, a sight taken to another station, the plates being clamped at 0°; the lower plate is then clamped and the upper unclamped and sights taken to the most prominent points of projection and recession of the face of the stope; these points being chosen about half way between the hanging and foot-wall of the stope, or preferably on the line of trend of the vein being stoped. The horizontal angle, the slope distance, and the vertical angle for each point, are recorded. By means of a table of latitudes and departures, or natural functions, or by logarithms the slope-distances are reduced to the horizontal; then on the plan, usually of a scale of 1 ft. = 240 ft., the horizontal angles are laid off and then the horizontal distance for each angle. The points thus determined are joined, thus forming the horizontal projection of the contour corresponding to that of the face of the stope. This contour, with that of the preceding survey, or in conjunction with the contour of the upper drift, or that of the lower drift, or of both, determines the horizontal projection of the area stoped. This area multiplied by the secant of the angle of dip is the slope-area corresponding to the area stoped. The dip is usually ascertained by sighting to a point on a rod at the same vertical distance above the foot-wall as the axis of the instrument, and held at a point in the line of dip as near as can be judged, and some distance from the transit. The vertical angle is read, giving the angle of dip; or the dip may be taken off the vertical section of the raise or winze from which the stope is being developed.

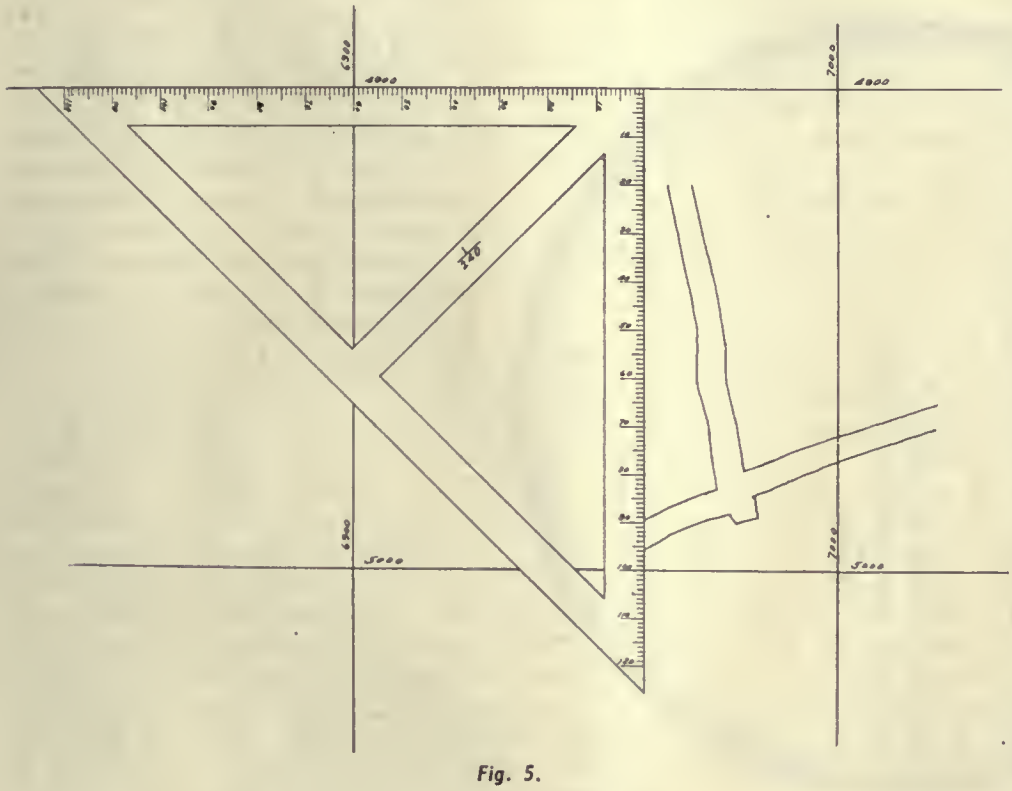

Fig. 5.

The method above described for surveying stopes in conjunction with the plotting protractor, and the methods to be described for determining the dip is a very advantageous one for all classes of stopes, flat, vertical, those with uniform dip and strike, or varying dip and uniform strike, or varying dip and strike, and those on a conical surface. The advantages lie in increased accuracy, a saving of time (as the notes of a stope-survey can be plotted in one-fourth the time ordinarily required, at the same time dispensing with all laborious reductions) and the cleanliness of the plans, as few if any erasures are neeessary.

The 'plotting protractor' (see Fig. 8) consists of a protractor *A* about 13 in. diam., graduated to 20 min.; 10 min. being easily estimated; numbered from left to right, as indicated, with two sets of figures, one set black and the other set red, 180° in advance of the black, the object of which will be explained subsequently. This method of numbering is used in conjunction with those instruments whose graduations are numbered from right to left. *B* is a quadrant, independent of the main graduated circle,

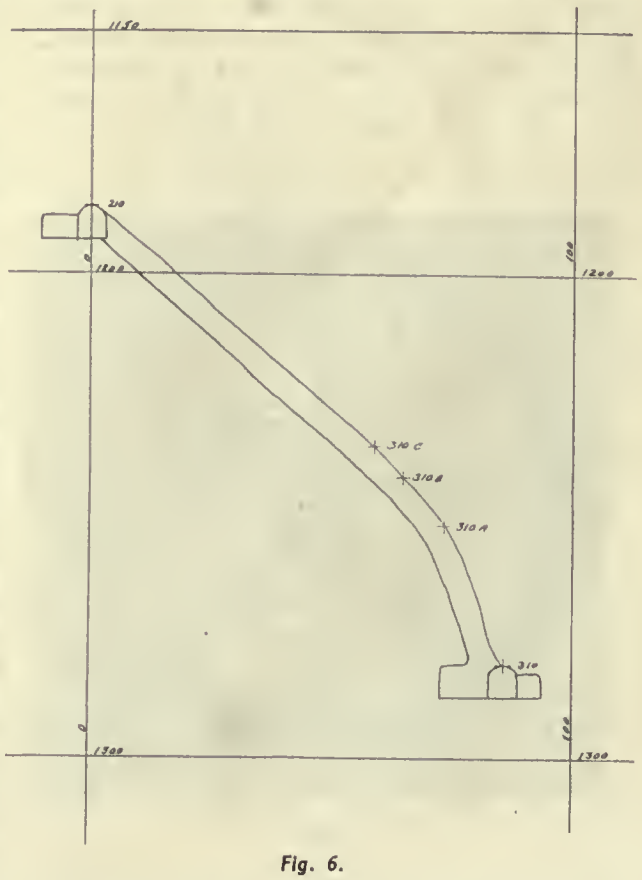

Fig. 6.

graduated to 20 min., and numbered with two sets of figures, one from 0 to 90° and return to 180°, the 0° division being opposite the 90° red, and the 270° black of the main circle. This set of figures is used in conjunction with those instruments whose vertical circle is numbered 0 to 360° from right to left and whose verniers read 90 to 180° when the telescope is level. The other set of figures is from 0 to 90°, the 0° division being opposite the 0° black and 180° red of the main circle. This set of figures is used in conjunction with those instruments whose vertical circle

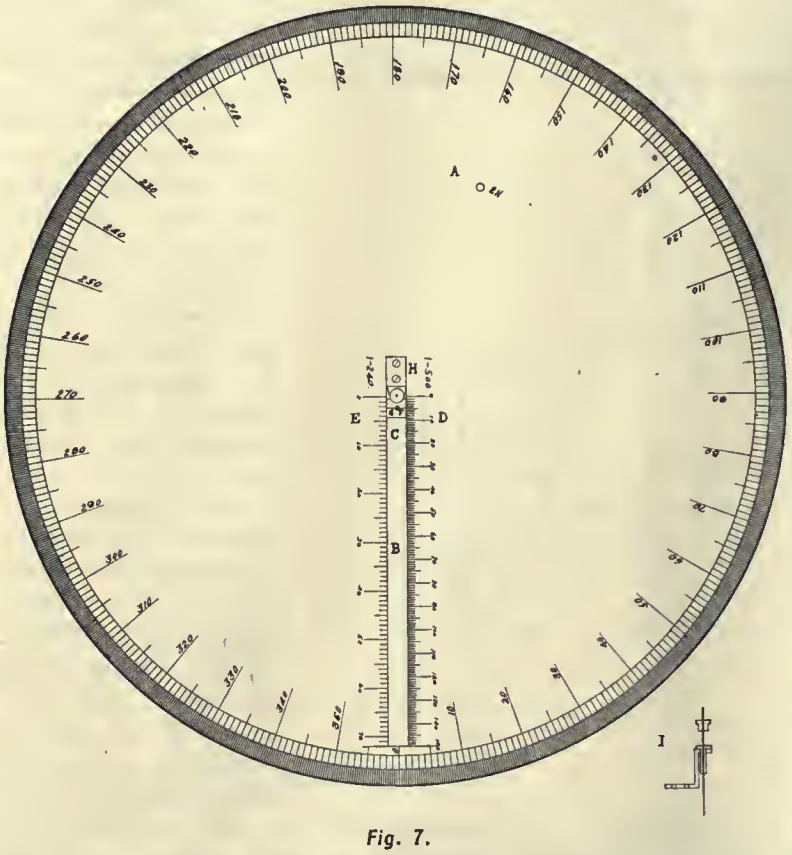

Fig. 7.

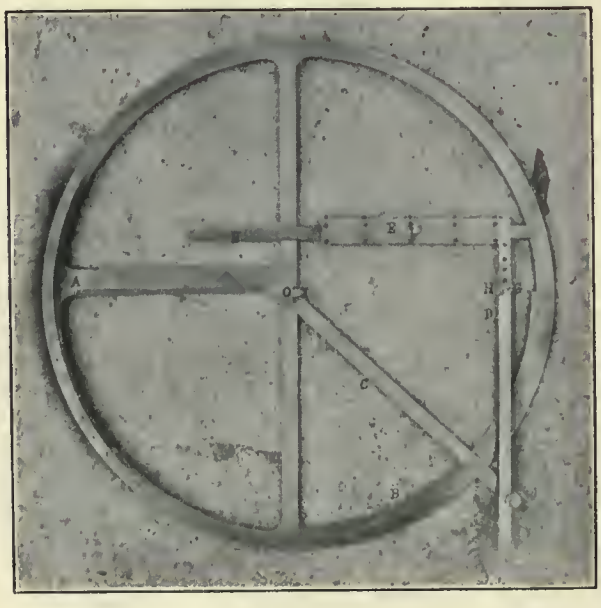

Fig. 8.

is numbered from 0 to 90°, to the right and left from 0°, and whose verniers read 0° when the telescope is level. *C* is a graduated scale (in this instance 1 to 240) and represents the slope-distance; *D* is a graduated scale (1 to 240) and placed at right angles to the line passing through *O*, the centre of the protractor, and 0° black of the main circle, and fastened to the slide *E*, which is movable along the guide *F*, so that the *O* division is always on line *O* 0°b. *G* is an upright through which passes vertically a needle *H* directly over the *O* division on scale *D*. This needle upon being pressed down makes a small mark on the surface of the paper and upon the pressure being released is returned to its usual position by a spiral spring. *I* is a fine needle over the centre of the protractor, and when not pressed down is retained free from the paper and also from dropping out when the protractor is not in use by a small flat spring. *A* corresponds to the horizontal graduated circle of the transit, *B* to the vertical, *C* to the measuring-tape, and *C*, *D*, *III*, is a right triangle in which *C* is the hypotenuse or slope distance, *D* one leg or vertical distance, *III* the other leg or horizontal, and *IIIC* the angle representing the vertical angle of elevation or depression. By this mechanical arrangement slope-distances can readily be reduced to the horizontal, and vertical distances determined without recourse to tables. As an illustration, suppose that the slope-distance is 100 ft., the vertical angle 30°: move scale *C* until 30° is indicated on *B*, then slide *E* until the edge *D* indicates 100 ft. on *C*, then read off on scale *E* 50 ft., the vertical distance; *III* is the horizontal distance, and is determined by revolving *C* to line *O*, 0°; 86.6 ft. is then read off as the horizontal distance.

To check *D*, that is, to ascertain if it be at right angles to line *O*, 0°, move scale *C* until 60° is indicated on *B*, then *E* until the edge of *D* indicates 100 ft. on *C*, then read off 86.6 on the vertical scale; then revolving *C* to line *O*, 0°, read off 50 ft. If there is any difference in the readings obtained by using 30 and 60°, *D* may be shifted by means of the screws by which it is fastened to *E* so that the *O* division is on line *O*, 0°, and also so that it is at right angles to line *O*, 0°. The upright may also be adjusted by means of the screws by which it is fastened to *D* so that the point of the needle when pressed down indicates *O* on scale *D*.

(To be Continued.)

The Haiditarod placers, which were discovered in the summer of 1909, may prove to be more important than those on the headwaters of the Innoko, according to the United States Geological Survey. Placer gold has also been found on Otter creek, which flows into the Haiditarod. Sufficient prospecting appears to have been done in this region to indicate the presence of a pay-streak 50 to 70 ft. wide, in which the gold is rather uniformly distributed. The information at hand indicates that these placers lie in what would be an extension of the Innoko auriferous zone.

Tres Hermanas Mining Distict, New Mexico.

By Waldemar Lindgren.

*About 25 miles south of Deming, New Mexico, and 10 miles north of the Mexican boundary the small group of mountains known as Tres Hermanas rises from the general level. The lead and zinc mining district is in the northern part of the group. The mines have been known for many years and have yielded a moderate production, possibly $200,000, principally from the Cincinnati vein and from the lead deposits in limestone near the zinc mines.

The predominating rock is a granite-porphyry, which forms the central peaks and is intruded in Carboniferous limestones, which occupy the foothills. Possibly the rock is more correctly to be classified as a quartz syenite porphyry. The northern foothills at the zinc mines consist of bluish-gray fossiliferous limestones of lower Carboniferous age dipping northwest at low angles. At the junction with the granite porphyry contact metamorphism is noted.

The lead deposits consist of normal fissure veins in granite-porphyry and typical contact-metamorphic deposits of lead and zinc in limestone near the contact with porphyry. Little work has lately been done on the veins, which are situated about one mile south of the zinc mines. The Cincinnati vein, owned by the Golden Cross & Eagle Co., is the largest producer, and is said to have yielded $100,000. It is stated to be a narrow vein in porphyry, rich in lead and gold. The ore was found within 100 ft. from the surface. Some ore has also been shipped from the Yellow Jacket vein, which is reported to be an extension of the Cincinnati. The Hancock vein, owned by C. E. Burdick, of Deming, is also said to be a narrow vein in porphyry, up to 8 in. wide. The shaft on this vein is 400 ft. deep. About 1000 tons of rich lead ore, with some gold, is said to have been shipped.

The zinc mines are situated at the northern base of the first porphyry hills. Old surface workings indicate places where formerly galena ores were mined. In 1904 attention was attracted to a heavy white massive or crystallized material occurring plentifully in the old workings and it was found to consist of carbonates and silicates of zinc. The property, which consists of five claims forming a compact group, was worked by Thurman & Lindauer, of Deming, in 1905, and a considerable number of carloads of ore were shipped to Mississippi Valley smelters. Some difficulty was experienced in obtaining ore of the requisite high percentage, and the systematic and careful development that the property seemed to deserve was not undertaken and it was practically idle in 1906 and 1907. Another group of claims adjoining the property on the northwest is owned by Deming men and some ore containing zinc and lead was shipped in 1906. The railroad freight from Deming to the smelters is $5 per ton, and the hauling to the station costs $2 per ton. Ore containing 29% of zinc was paid for by the smelters at about $11 per ton, and 37% ore yielded approximately $16.50; obviously the lower grade left but little profit. The developments are slight, consisting of a few shallow inclines and surface cuts.

The traveler approaching Tres Hermanas from the north first encounters a low broad limestone ridge, separated from the higher and more abrupt hills of porphyry on the south by a low gap. The principal zinc mines lie on the west side of this gap. At the principal workings there is a small hill with limestone which lies flat on the top, but bends to dips of 20° on the north, west, and south. The actual contact with the porphyry south of the gap is not well exposed, but near it the limestone contains several well defined dikes, and in one place a projecting broad tongue of porphyry distinctly cuts across the strata. Contact metamorphism is clearly manifest, the affected zone being in places over 1000 ft. wide. The principal complex of limestone northwest of the gap is, on the whole, not metamorphosed, but even here, more than half a mile north of the contact, a few thin beds of garnet rock and coarsely crystalline limestone are noted. In the gap the crystalline limestone prevails, with intercalated beds of pure garnet rock and hornfels, the latter evidently representing a contact-metamorphosed lime shale. Some of the strata exposed here contain well preserved specimens of *Spirifer* and *Fenestella* and look like limestone, but, in fact, the rock consists very largely of garnet. The principal zinc workings, about 2000 ft. west of the gap, are in limestone, in which the only sign of alteration consists of bunches of wollastonite.

The deposits contain oxidized zinc minerals and some galena; they lie in part parallel with the stratification, but in part they follow short and ill defined nearly perpendicular fissures and veins cutting across the beds and varying in strike from northwest to southwest. The ores also in places form irregular bunches in the limestone. Several small deposits of the two latter classes are present on the main limestone hill, in many of the prospect holes sunk there, but have not yet been proved to be of value. A short distance north of the principal gap, oxidized zinc ore occurs in kidneys and bunches between beds of coarsely crystalline limestone and garnet rock. A vein-like deposit striking N. 60° E. and standing nearly vertical also contains zinc ore at this place. Many of the prospect holes in the area of most intense contact metamorphism in the gap or immediately east of it have also given assays high in zinc. The principal developments, about 2000 ft. west of the gap, consist of surface pits and small shafts with irregular workings. Here the oxidized zinc ores occur in the greatest abundance, in part parallel to the strata, in part along a vein with west-northwest strike. Little intelligent prospecting had been undertaken in 1905, the deepest hole having attained only 35 ft. from the surface. The ore grades into limestone, and great care must be exercised to avoid mixing with barren material. A few green stains are the only indications of copper minerals found. Possibly exploration may develop more of this metal in beds at greater depth.

*Abstract from 'Contribution to Economic Geology', 1908, U. S. Geol. Surv., Bull. 380.

Sources of Error in Analyses.

Written for the MINING AND SCIENTIFIC PRESS
By R. C. BENNER.

Some of the common mistakes which occur in the chemical laboratory are due to incorrect calibration of weights and volumetric apparatus. Many chemists take for granted that anything which is stamped by the manufacturer as weighing a gram, or holding a litre, must necessarily do so. But weights once correct may have become incorrect by wear or corrosion by fumes from the laboratory. The better class of weights made by a reliable manufacturer will, in most cases, be sufficiently accurate for any work that the analyst is likely to undertake. Cheap weights should not be used for work where accuracy is required, not only on account of their probable inaccuracy, but also because of the ease with which they corrode and change weight. Gold and platinum-plated weights should be used, and in order to be sure of their accuracy, should be tested against one another, against a standard weight, or, still better, if very accurate work is to be done, they should be calibrated by the Bureau of Standards at Washington, D. C.

Testing of weights is easy and can be accomplished as follows: It is necessary first to determine the sensitiveness of the balance used in testing the weights. Sensitiveness of a balance is the number of scale divisions displaced by the pointer when a weight of one milligram is placed on the pan. All of these determinations are made by the method of swings, which is sufficiently accurate for the purpose in hand. Let the divisions on the ivory scale be numbered from left to right of the zero point (Fig. 1). The point of rest is then found by setting the

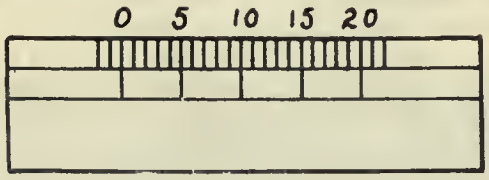

Fig. 1.

balance in motion and, after the first two or three swings, the extreme position of the pointer is recorded, taking an odd number of readings, say three to the left and two to the right. The results are arranged as follows:

Left.	Right.
1.3	19.9
2.0	19.6
2.3	2 | 39.5
3 | 5.6	19.7
1.9	1.9
	2 | 21.6
	10.8

The point of rest at this particular time is thus 10.8. The point of rest with one milligram on the right-hand pan is next determined in the same manner as when there is no weight on the pan. Suppose that the result obtained is 7.6. The difference between the two points will give the number of scale divisions that one milligram will displace the pointer. This is the 'sensitiveness' of the balance. This is used in the following manner for the determination of the weight of an object. The object to be weighed is placed on the left-hand pan and balanced to the nearest milligram, by placing the weights on the right-hand pan. Suppose that when 10.561 gm. is the weight placed on the right-hand pan, the point of rest is determined to be 13.01. One milligram is now added by means of the rider and the point of rest found to be 10.30. The sensitiveness for this load is the difference between these two readings, that is, $13.01 - 10.30 = 2.71$ scale divisions. The true weight is then computed from these data in the following manner. Subtract the point of rest of the balance without a load from the point of rest with the load, that is, $13.01 - 10.80 = 2.21$ scale divisions. This gives the number of scale divisions that the point of rest with the load differs from the point of rest of the balance. The ratio between this value and the sensitiveness gives the weight it takes to move the pointer 2.21 scale divisions or the amount to be added or subtracted from the observed weight 10.561. For example: $1 : X :: 2.71 : 2.21$. Here $X = 0.78$ mgm. to be added to the observed weight. $10.561 + 0.78 = 10.5618$ grams, the true weight of the object weighed. The sensitiveness of the balance as a rule varies slightly with the load, so that it is better to determine the sensitiveness for a series of weights once for all. 1, 2, 5, 10, 20, and 50-gram weights are those generally taken. The zero point for accurate work, such as the testing of weights, should be determined at the beginning and at the end of each weighing, taking the mean of the values thus obtained.

In most sets of weights there are one 50, one 20, two 10, one 5, three 1, one 0.5, one 0.2, two 0.1, one 0.05, one 0.02, two 0.01-gram weights and also a rider which is used in making weighings which are carried out farther than 0.001 gm. In testing such a set of weights, the assumption is made that the sum of the larger weights is equal to 100,000 milligrams, and then each is compared with the other members of the set in the following manner: The 50-gram weight is tested against $20 + 10 + 10 + 5 + 2 + 1 + 1' + 1''$. By this method of double weighing these are compared with one another, that is, comparing, and then changing the weights about. Those which were on the right-hand pan are placed on the left-hand pan and those which were on the left are placed on the right-hand pan and the weighing repeated. In this manner it makes no difference if the two balance arms are not of equal length. If the absolute value is desired a standard weight is necessary.

Example: Left. Right.

(1) 50 gm. + 0.15 mgm. = 20 + 10′ + 10″, etc.

(2) 20 gm. + 10 + 10′ etc. = 50 gm. + 0.30 mgm.

from which we get by averaging

$$50 \text{ gm.} \frac{0.15 \text{ mgm.} + 30 \text{ mgm.}}{2} = 50 \text{ mgm.} + 0.22 \text{ mgm.}$$
$$= 20 \text{ gm.} + 10 + 10' \text{ etc.}$$

or

$$50 \text{ gm.} = (20 + 10 + 10' \text{ etc.}) - 0.22 \text{ mgm.}$$

When the other weights are compared in a similar manner we obtain the following table:

50 gm. = 20 + 10 + 10′ etc. + X mgm.
20 gm. = 10 + 10′ + Y mgm.
10′gm. = 10 + Z mgm.
5 + 2 + 1 etc. = 10 + M mgm.

In these equations X, Y, Z, and M can be either positive or negative. Remembering that the sum of all of the weights is assumed as equal to 100,000 mgm., we obtain from the preceding equations,

$$10 \times 10 + X + 2Y + 4Z + 2M = 50 + 20 + 10 + 10' \text{ etc.} = 100{,}000 \text{ mgm.}$$

transposing and dividing by 10.

$$10 = 10{,}000 - \frac{X + 2Y + 4Z + 2M}{10}$$

$$\text{now let } \frac{X + 2Y + 4Z + 2M}{10} = N$$

By means of the equations above, we obtain the following values of the larger weights. Those of the smaller are found in exactly the same manner.

$10 = 10{,}000 - N$
$10' = 10{,}000 - N + Z$
$5 + 2 + 1 + 1' + 1'' = 10{,}000 - N + M$
$20 = 20{,}000 - 2N + Y + Z$
$50 = 50{,}000 - 5N + X + Y + 2Z + M$
$= 50{,}000 + 1/2X$

If the operations are carried accurately $1/2X + Y + 2Z + M - 5N$ should be equal to zero.

Although graduated glassware is as likely to be incorrectly calibrated when it comes from the manufacturer as are weights, it is not nearly as likely to become inaccurate by use, for the reason that weights lose their accuracy unless carefully protected from all fumes. When the glassware is once correctly standardized, the standardization is practically permanent for ordinary purposes. In glassware, as in case of the weights, it is not necessary that any graduated instrument should have a definite volume, but all instruments used in the same laboratory should be calibrated against one another. It is also desirable that the glassware should be calibrated with the set of weights which is used with them. The volumetric glassware commonly used consists of burettes, pipettes, measuring flasks and graduated cylinders.

The flask to be graduated is usually one which the manufacturer has already calibrated and must be checked, or one which has been made for the purpose, having a long cylindrical neck about 17 mm. diam. It is first cleaned with a solution of potassium bichromate in concentrated sulphuric acid, so that when the flask is filled with water and allowed to drain no drops will be left clinging to the sides of the flask; then it is dried thoroughly and balanced on one pan of a balance that will carry a load of 1.5 kg. or more on each pan and be sensitive to one decigram. A kilogram weight is then placed on the opposite pan and the flask is filled with distilled water at 17.5°C. until the weight on the opposite pan is balanced. All drops of water above the meneseus are wiped off with a piece of filter paper and equilibrium restored by adding or removing a few drops of water with a thin glass tube of small bore. This being accomplished, a piece of gummed paper with a straight edge is placed around the neck of the flask so that its edge is tangent to the bottom of the meneseus. The flask is emptied, dried, and the operation repeated as before, the average of three readings being taken as the correct one.

A pipette when it is calibrated should be cleaned in the same way as the flask. When clean, a long narrow strip of paper is pasted along the neck of the pipette. The pipette is now filled with distilled water at 17.5°C. from any ordinary pipette that may happen to be at hand, and the position of the meneseus noted in the paper. A glass stoppered bottle is now placed on the balance and the contents of the pipette allowed to flow into it, the last drop being removed by touching the side of the flask with the end of the pipette, always repeating the operation of discharging in the same manner. The flask is then stoppered and weighed. If the weight is too much or too little, a larger or smaller amount is measured into the pipette and the bottle weighed as before and another mark noted on the paper. This is continued until the correct amount of water is obtained. This volume of water is then weighed three times and the average taken as correct. The mark is etched on the glass with hydrofluoric acid.

Burettes are most conveniently standardized after the manner of Ostwald. The apparatus needed is shown in Fig. 2. The small pipette and the burette are cleaned with the chromate sulphuric acid mixture. After cleaning, the small pipette is filled with distilled water exactly to the mark at A by pressing the glass bead in the rubber tube at X; Y is opened and the water allowed to run into a tared beaker until the lower mark at B is reached (the pipette should always be drained a minute before the final reading is taken). This water is weighed, the whole operation repeated two or three times, and the mean taken as the correct content of the pipette. Fill the burette to 0 and the pipette to B with water at a constant temperature, not necessarily at 17.5°C., press X, allowing the pipette to fill to A, always draining one minute before the reading is taken. Then discharge the pipette to B by pressing Y, allowing to drain one minute as before. The reading on the burette, if it be calibrated correctly, should of course check with that on the pipette. The readings are usually repeated after the burette has been checked throughout its length. From the readings thus obtained it is easy to construct a curve from the average readings as abscissae and the total corrections as ordinates.

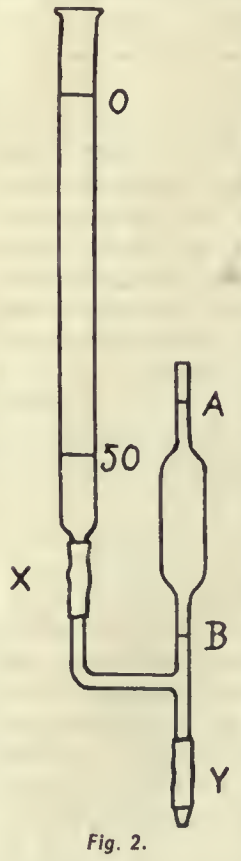

Fig. 2.

Antimony may be separated from other metals contained in an alloy by taking advantage of the fact that the Sb oxides obtained by the treatment with HNO_3 are rendered completely insoluble in HNO_3 by heating to 125 to 150° Centigrade.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Oriental Trade and American Shipping.

The Editor:

Sir—Anent Thomas T. Read's views of the relations between trade and transportation, as mentioned in your issue of February 5, one phase of this relation will probably be remembered by San Francisco merchants of 30 years ago. Until the Southern Pacific was opened through Arizona the British engrossed the trade of Sonora. As soon as the road was opened American goods, notably cottons, drifted down on pack trains. They were so much better and cheaper than the British cottons then sold in Sonora that about the time they reached Hermosillo the Guaymas merchants found their staples unsalable. Eventually these samples of 'peace on earth and good will towards men', as I was told by one of the firm of Cabrera & Romá, were taken away from Guaymas by the British factors to be vended where American transportation facilities did not preclude their sale.

There are few who do not know that our control of the railroads leading into Canada and Mexico has given us more than half the imports of those countries, or that the enforcement of our coasting laws as to the trade of Hawaii and Porto Rico gives us 80 to 90% of the imports of those islands. On the other hand, we sell the Philippines between 16 and 17% of their purchases with the carrying trade between them and this country open to the competition of the world. In the meantime the four lines of foreign tramps our Government employs to carry its freights to the Philippines, discriminate against Mr. Read's ability to get American goods in Tientsin. The Germans, whose subsidizing of a steamer line to the Far East is too notorious to be denied, not only beat us in the literature on the subject, but as Mr. Read shows, in their delivery of goods. England, as is well known, does not subsidize its shipping, but according to Henniker Heaton's often quoted letter to the London *Times* the P. & O. S. S. Co. is paid £365,000 annually, or $4880 per day, 'for carrying the mails'. Our sales to the Orient, including India and China, but excluding French Indo-China and the Philippines, averaged for the three years ended with 1906, $47,500,000, while England averaged $315,000,000, a pretty fair trade-return for an annual expenditure of $1,780,000.

An incident in our cotton trade with the Philippines seems to have escaped general notice. On February 26, 1906, an amendment was made to the Philippine tariff of which the 'Altruistic' Ide (afterward a receiver for Knickerbocker Trust Co., of New York), said (see Report of Philippine Commission, 1906, Part I, p. 63, and Part III, p. 14), "by changes in the cotton schedule of the Philippine tariff such as to increase the price of cotton goods in the islands for the benefit of manufacturers of cotton goods in the United States, changes which were made discriminative in such a way as to exclude foreign manufacturers and thereby enable American manufacturers to fix their own prices," etc. In 1907 we sold the Filipinos 13.6% of their cottons, while the United Kingdom and its dependencies sold them 52.5. In 1908, however, we sold only 8.5 and England 55.8. In 1909 our sales were again 8.5%. The result has not justified the expressed fear of discriminations in favor of American manufacturers.

This result may be ascribed to the fact that the United States Government, by its policy, gives ample employment to British ships and withholds employment from American ships, putting it in the power of our rivals to so manipulate freight rates as to transfer that trade to manufacturers in Great Britain. This has been done in other instances. The excess for 1908 in the sales of British cottons of over three and three-quarter million dollars, sufficient to support 7000 to 8000 people, must have been eminently satisfactory to British farmers, manufacturers, and middlemen, with all those in any way dependent upon them. But no American, farmer or otherwise, except those who dare not admit it, received any benefit.

An examination of the tables in the Bureau of Statistics, 'Statistical Abstract of Foreign Countries', Washington, 1909, particularly of Table 2, will show conclusively that when we control the means of transportation our share in the sales of commodities is satisfactory. When the demand for our commodities is great enough, our rivals will put on lines of steamers to curtail our market. Incidentally it will be noticed in the 'Abstract' referred to, that of the total Turkish imports (my remarks on which Mr. Read thought 'ridiculous'), we sell to that country about one-quarter of one per cent. If we get concessions there, as is now hoped, rivals will put on lines of freighters to make freight rates satisfactory to European producers, but no passenger lines that might encourage greater personal knowledge of Turkish wants.

The readers of the MINING AND SCIENTIFIC PRESS may be assured that this fight against American shipping is not solely a fight to retain all of the $250,000,000 which we pay yearly to foreign over-sea carriers; it is a fight to keep us from access to those small markets in which the largest percentage of profits is made. And no narrative of bad packing can rub this out. Mr. Read's skepticism as to the 'possible advantage' accruing from the betrayal of the interests of this country, will excite a smile from those who have read of the sugar trust's swindling, and have noticed the support both political parties gave the late Henry Havemyer. A somewhat similar case, of special interest to the Pacific Coast, lies in the statement made lately, that the coal lands of Alaska have been saved to the people of the United States, that is to say, their development has been indefinitely postponed. Now comes Arthur Brownell in the *Outlook* who says: Our navy on the Pacific burns approximately 400,000 tons of coal annually, most of which comes from Wales. The development of our Alaskan coalfields would save the Government about $4,000,000 per year. For the sake of that will the Alaskan coal-

fields be developed? No, they will be reserved for future generations of the American people, and all the foreign carriers will help to sustain the policy. In the meantime San Francisco and the active Pacific Coast will be prevented from adding to its wealth thereby through manufacturing.

EDWARD P. NORTH.

New York, March 8.

Alfred James' Annual Cyanide Letter.

The Editor:

Sir—In your issue of February 26, I notice two letters by E. M. Hamilton and John M. Nicol, respectively, in which they take exception to certain statements made by Alfred James in his annual cyanide letter. I am quite in sympathy with both these gentlemen. While at Kalgoorlie, Western Australia, I presume I handled a larger tonnage than any individual manager in that district with the Dehne filter-press. The combined tonnage of the following mills was all handled by that press: The Great Boulder Perseverance Gold Mining Co., Ltd.; The South Kalgurli Gold Mining Co., Ltd.; The Hannan's Public Crushing Co., Ltd. These three properties had a combined tonnage of over 35,000 tons per month, all handled in the Dehne press.

My experience, which covered a period of over eight years, taught me that you could not secure a perfect wash with it. This was particularly true where the product going to the Dehne press was not carefully classified. The cakes chanceled and there was more or less gold in solution thrown out with the sand or tailing. This prompted me to investigate the Moore vacuum filter and with its use I had the tailing from most of the mines in the Kalgoorlie district tested, extracting gold with the Moore vacuum filter by simply washing discarded tailing from the dumps of all the mines in the district. I had a great number of tests made by A. J. Wyly under my personal direction. We improvised a small unit of the Moore vacuum filter, but the results were all most satisfactory and showed conclusively that the washing of an unclassified product was more efficaciously done in the Moore filter than a classified product in the Dehne press. The amount of gold in solution in the tailing from the Moore filter was uniformly low, and I know of no filter where the washing is so perfectly done. I am satisfied that there is no comparison between the Dehne filter-press and any of the submerged types of vacuum filters now in use. All of these vacuum filters are superior in every way as to costs and efficiency to the Dehne, and it is for this very reason that George Moore invented and introduced the first successful vacuum filter at the Mercur mill in Utah, U. S. A. The facts brought out by the numerous tests made with the Moore vacuum filter at Kalgoorlie were never published, but copies of results were given to all the managers on the Golden Mile. And the reason why so many Dehne presses are in use today in Westralia is because the installation of these presses was effected at great expense. English conservatism, in this case resulting in extravagance, has since kept them in use.

RALPH NICHOLS.

Gilmore, Idaho, March 8.

Gold Mines of Tibet.

The Editor:

Sir—Imagination is a great gift, but its use in technical journals should be tempered with discretion, if not with knowledge. This thought is brought to mind by a perusal of an article in your issue of February 12, entitled 'Gold Mines of Tibet'. The encyclopedic information of the first three columns I will not venture to criticise; it seems exhaustive and eclectic; but the geographic and other information of the last two paragraphs strains my credulity to the utmost. I have seen nothing like it since the publication of Gelett Burgess' 'Map of Bohemia'.

When the writer tries to identify Tibet and Siberia and mentions the tundras of the former, it is bad enough; but when he goes on to mention "the Island of Liakoff, north of the Manchurian tundras" and speaks of the "Yukutsk fair," one suspects him of attempting to perpetrate some humorous hoax.

Everyone knows that a certain number of prehistoric elephants have been found imbedded in the ice in the northern *taiga* of Siberia and that objects carved from this ivory are to be purchased at the fair at Irbit, some thousands of miles west of Manchuria; and it also is generally known that the skeletons of several mastodons have been unearthed in the *tundra* of northwestern Siberia, as the result of prospecting for mines, and now rest peacefully in the museums. But when the author of the article in question says that "these tundras are in places full of the carcasses of elephants and rhinoceroses preserved in ice, both of them still yielding ivory of a marketable value," he is wafted away on the wings of his imagination quite beyond the range permissible in a technical journal. In stating that recently nearly a hundred carcasses were found practically in a single cluster, and that in 1898 no less than 80,000 lb. of fossil ivory were offered for sale at the 'Yukutsk' fair, he very nearly approaches Baron Münchhausen at his best.

JEROME B. LANDFIELD.

Binghamton, N. Y., March 1.

English in Our Technical Journals.

The Editor:

Sir—In your issue of March 5, Mark R. Lamb takes opportunity to file objection to a part of my letter to you, which appeared in your issue of November 13, 1909. Mr. Lamb's objection is based upon a fallacy; which itself is beside the point. I therefore wish to submit the following as more clearly defining my position.

Mining, smelting, cyaniding, etc., from the point of view of mere technique are mechanical operations; but the engineer, who investigates and directs the application of scientific principle, making these operations possible, is not a mere automaton, but a thinker. This view identifies him with technical philosophy. The discussion and interpretation of these mechanical operations forces him to assume the rôle of philosopher whether he would or not. This assumption recognizes him as a representative type of a species. As a result of the application of the law of selection, this representative type should produce the best that is in the species. I am sure that Mr.

Lamb is not ready to admit that careless thinking and careless writing is the upper limit of the capabilities of this type specimen. If this be the upper limit, the species is in need of re-classification. If there is room for improvement then it is plainly unfair to put the entire responsibility of revising and rewriting current technical literature upon the shoulders of the editors of technical journals. My letter was written in the spirit of constructive, not destructive criticism. It was not my intention to assume a scornful attitude, but it was my intent to call attention to an evident deficiency in one of the fundamental sciences of learning. I am convinced that to work with the determination to improve, even our best, shall result in broadening and deepening our knowledge of natural law to such an extent that the application of theory to practice shall become easier, thereby putting into our hands the knowledge of the better use of a most excellent tool. I have a further deep conviction that what is fittest shall survive, and I believe also that every man owes it to posterity to give to it the best of which he is capable, be that little or much. In other respects Mr. Lamb's objection is its own reply.

W. W. STRANGE.

Pony, Montana, March 13.

Pan-Americanism.

The Editor:

Sir—As a resident in Central America I venture to disagree with your editorial on Pan-Americanism of December 18. I do not think that the cause of revolutions can be so easily and lightly laid at the door of the grafting foreigner. Revolutions in Central America are simply the natural method used by the party that is out of power to eject the rival party. It is their way of electing a new government. The method appeals to the theatrical nature of the Latin-American, and the only way to cure him is to educate him out of it, by showing him what good government really is. The United States, as a great Anglo-Saxon nation, cannot afford to shirk its responsibility, but must take its share of the 'white man's burden'. As these turbulent little republics are as yet unable to be responsible for themselves, someone must be responsible for them, and for their behavior. Granted that the United States does not desire additional territory, nevertheless she must not wince under the insinuation of 'land grabbing' nor permit continual bloodshed and disorder under the protection of the Monroe doctrine.

SANGRE.

Managua, Nicaragua, February 10.

[We are glad to have the opinion of one resident in Nicaragua tending to exculpate Americans from responsibility for the recent upheaval. We are willing to concede that the revolutionary proclivities of the 'ins' and the 'outs' in Latin-America have offered superior opportunities to foreign corporations to entrench themselves by financing such demonstrations to the end of insuring a subservient administration. The revolutionary method was an evolutionary method in Spanish-America until it became the instrument of grafting foreign corporations. The stench of the asphalt case in Venezuela still offends all decent Americans, and the circumstances that brought on the revolution at Bluefields had more to do with the fruit business of American importers than with the personal ambitions of Nicaraguans. The ambitions might have been there, but the sinews of war had to arrive from the United States before the warrior-politicians found the courage to back up their convictions. The duty of the United States is clearly to protect the lives and property of all its law-abiding citizens, resident in foreign lands, and to do it with warlike emphasis when diplomacy fails, and its further duty is to refrain from pressing weak governments to pay the illegal claims of grafting corporations as too commonly it has done, sometimes with insufficient knowledge of the facts, and sometimes without regard to them. The sooner the Government at Washington adheres to these lines the sooner will revolutions in Spanish-American countries cease to be profitable.—EDITOR].

Silver on Filter Leaves.

The Editor:

Sir—While recently overhauling some vacuum filter leaves, which had been used in filtering silver-bearing solution from Tonopah ore, I noticed a metallic white plating or scale on exposed, that is, unpainted iron parts of the filter-leaf and where the paint was rubbed off. This occurred both in spots in the iron piping inside the canvas cover and also on the nails in the wooden head-piece. Selected portions of this scaly material proved to be silver, when tested. It would be interesting to know how much silver is deposited inside the solution piping in various cyanide mills of the United States, or in Guanajuato and Pachuca. Probably the total amount is not great, but it may still be more than most people think.

DONALD F. IRVIN.

Bodie, California, February 26.

Cyanide History.

The Editor:

Sir—I have read Alfred James' letter in your issue of September 25. I have nothing to withdraw from my letter on 'The Vacuum Pump in Cyaniding' inserted in your issue of July 3, and principally because I think the prolongation of this controversy is of no real interest, I have nothing to add to that letter.

JOHN S. MACARTHUR.

Glasgow, October 22.

[The delay in printing of the above letter has been due to our not understanding in the first instance that it was offered for publication.—EDITOR.]

Selenium in Washington.

The Editor:

Sir—The discovery of a selenium mineral in gold-bearing quartz from the Republic district, Washington, was announced by Waldemar Lindgren at a recent meeting of the Washington Geological Society. Selenide of silver has been known from this State for some years. I reported its occurrence in *The Engineering & Mining Journal* November 25, 1899.

M. H. JOSEPH.

Republic, Washington, March 21.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The Mint does not buy gold dust or old gold in lots of less value than $50. Smaller quantities may be sold through brokers.

Leases granting the right to extract ore from a certain level of a mine involve the right of extraction to the next level above.

Mining locations may overlap previously acquired territory, whether patented or not, or whether the latter is agricultural or mineral, or whether the inclusion of such land is due to accident or design, or by the consent of its owner, or without such consent if peaceably done.

Bromine is obtained largely in Michigan as a by-product from the salt industry. It is also made in Ohio, Pennsylvania, and West Virginia. The total output is only about one million pounds per annum, the low price not stimulating a larger production. The bromine exists in the brine as the bromide of magnesia, the amount seldom exceeding two grams per kilogram.

Adobe is a name given to plastic clayey soil which has the property of setting when dry, without burning. The term is not properly applied to clay alone. In the semi-arid regions of the Southwest and Mexico such soils abound, and furnish the material for sun-dried bricks, also called 'adobes'. The plasticity of adobe soils is due to the same causes as that exhibited by ordinary clays.

Production of the St. John del Rey mines, in Minas Geraes, Brazil, for the first half of 1909 amounted to £197,495, from 96,021 tons of ore. The company owns the Morro Velho and Guynbá mines, in which ore reserves to the extent of over 1,000,000 tons have been developed. The plant consists of 120 stamps, and 7 tube-mills. It is the largest gold mine in Brazil, and has one of the deepest shafts in the world.

Cement-rock is a limestone containing such proportion of clay that, on being burned and then ground, it will develop the property of 'setting' when moistened. To produce a portland cement the material when burned should show a composition of approximately 62% lime (CaO), 20 silica (SiO_2), 6 alumina (Al_2O_3), and 7 ferric oxide (Fe_2O_3). The remaining 5% will consist of various substances, such as magnesia, potash, and titanic acid.

Nickel was produced in the United States in 1908, according to the United States Geological Survey, at Fredericktown, Missouri, from the ores of the North American Lead Co., and from one lot shipped by the Nevada Nickel & Copper Co., having mines at Bunkerville, Lincoln county, Nevada. Some nickel salts also were made by the United States Metals Refining Co., at Crome, New Jersey, from electrolyte solutions obtained in refining copper. The principal source of nickel, however, was ore imported from Sudbury, Canada, where the Orford Copper Co. and affiliated concerns have mines. The imports for the year were: nickel and nickel alloys, 227,584 lb., worth $86,905; ore and matte, 16,586,423 lb., $2,396,217; nickel oxides, 11,284 lb., $4483.

Sulphur Bank is the name of a famous quicksilver mine in Lake county, California. It is a classic spot for geologists because it presented the interesting phenomenon of ores in process of deposition from solution in a solfatara which was not entirely extinct. The cinnabar does not occur near the surface, but is found below the limit of oxidation, mixed with native sulphur. Marcasite is also present, with small amounts of gold. The property has been a large producer of quicksilver.

Paints for protecting iron-work should be made of pigment containing three different sizes of particles. Such a coating is much more impervious and durable than a paint containing one or two sizes of pigment particles only. This fact has been determined by careful tests by the scientific section of the Paint Manufacturers' Association. Researches conducted by Allerton S. Cushman show that certain paints promote corrosion of iron and steel, others are inert, while still others actually prevent corrosion.

Weights and measures should be used as below, according to a report adopted by the Institution of Mining and Metallurgy: (a) The word 'ton' to represent a weight of 2000 lb. avoirdupois (29,166.6 oz. troy). (b) The word 'gallon' to represent the Imperial gallon measure of 10 lb. of water. (c) Temperatures should be expressed in degrees Centigrade. (d) Returns of gold and silver should be expressed in terms of fine gold and fine silver, respectively, not as 'bullion'. (e) Gold contents of ores, etc., determined by assay, should be expressed in money values as well as in weights; and in this connection the value should be taken (as a convenient constant) at 85 shillings or $20.67 United States currency, per troy ounce of fine gold.

Halley's comet, according to W. H. Pickering, has been identified as a member of the solar system for over 2000 years, but certain characteristics of its orbit suggest that it has been with us at least ten or perhaps one hundred times as long as that. According to all accounts, it was a magnificent object at the time of the Norman conquest in 1066. Its head was equal to the full moon in size, and its tail increased to a wonderful length. Comets whose periods are less than one hundred years are called periodic comets, and nearly half of them have been observed more than once. At present they number forty-five, but only three of them are retrograde; that is, revolve in their orbits in the opposite direction to the planets. Halley's comet is one of these three, and as a result it will pass the earth with a very rapid motion. At that time the earth will be moving in its orbit at a speed of eighteen miles per second, and the comet in nearly the opposite direction at a speed of twenty-five miles. The relative motion is, therefore, about eighty times that of a cannon ball.

Special Correspondence.

NEW YORK.

Anaconda-Amalgamated.—Con. Arizona.—Granby Con. — Wettlaufer-Lorraine.—Markets Dull. — Copper Stocks. — Braden Copper.

The Amalgamated Copper Co. owns practically all of the stock of the various companies recently taken under control by the Anaconda with the exception of Red Metal, which is a holding company owning the direct title to the Butte Coalition properties and stock control of the Alice. The Amalgamated ownership in Anaconda, held previous to the increase in the capital stock, together with the additional stock which it will receive in exchange for its holdings in various companies, will give the Amalgamated about 3,075,000 shares of Anaconda, being a little less than three-quarters of the total stock issued while there will remain in the treasury of the Anaconda 1,780,000 shares. It is estimated that the Anaconda will have a copper production of more than 250,000,000 lb., which will be produced at something less than 9c. per lb., after crediting gold and silver profits and the net revenue derived from lumber and coal properties and railroad operations. On a 13c. copper market this production would figure a net profit of about $10,000,000 per annum. The new company's net quick assets are figured at about $25,000,000. It has been suggested that one of the main reasons for carrying through the Butte merger at this time is that the Amalgamated Copper Co., in the event of an adverse decision in either the American Tobacco case or the Standard Oil case by the Supreme Court of the United States, might find itself an outlaw; whereas the Anaconda Copper Co. is a Montana corporation and its direct operation of the Butte mines would not in any way render it amenable to the Sherman law. Upon this point will undoubtedly turn the eventual destiny of the Amalgamated's organization and its dissolution. The Consolidated Arizona Smelting Co. has just made a report of its financial condition, showing an issued capital of $8,167,475, with no debts; the cash balance on hand is $292,792 with accounts receivable of $52,437. The new company is developing its Bluebell mine near Humboldt, Arizona, and is said to have re-built and enlarged the old Humboldt smelter, and to have recently secured a contract to handle a considerable tonnage from the United Verde. The action of the Granby Consolidated Copper Co. has attracted a good deal of attention to the Boundary camp. This property has recently been examined by Otto Sussmann, of the American Metal Co., and while his full report has not as yet been made to the stockholders, it has been semi-officially announced that his report will show only some six million tons of ore available for stoping. This information, coupled with the announcement that the dividend of $2 which was expected to be declared in April will be deferred, was sufficient to cause a 33 point break in the stock. The American Metal Co. is the American agent for Merton & Company, Ltd., of London, and is an extensive dealer in copper and other metals. This concern is said now to be working in conjunction with Thomas F. Cole on the formation of a second consolidation of Butte properties to include the Butte & Superior, and the other principal zinc producers of the camp. The Silver Mines Exploration Co., through which the Lewisohns carry on their operations in Cobalt, has made its second payment on the Wettlaufer-Lorraine Silver Mines Co. Some market capital was made out a rumor that the option which the Lewisohns held, was to be allowed to lapse; the story was evidently without foundation. Eastern mining markets for the past few weeks have been exceedingly dull. The political situation is tense, and the action of the Supreme Court in the Standard Oil and American Tobacco cases is of so great importance that the markets have assumed a waiting attitude. Copper exports are expected to show a considerable falling off for March, but domestic deliveries will, it is anticipated, show a satisfactory increase over February. There will probably be no great decrease in the copper surplus shown by next month's figures, but the following 60 days should make such inroads into stocks that what remains will be only a safe margin. Pope Yeatman cables from the Braden Copper Co.'s mines in Chile, that the orebody of the Fortuna mine is much larger than previously estimated. Mr. Yeatman figures now 7,000,000 tons, averaging 2.94%, as against former figures of 4,500,000 to 5,000,000 tons, averaging 2.70%. William B. Thompson, of Thompson, Towle & Co., of New York, has returned to New York from a trip of inspection which included the El Rayo Mines Co., of Santa Barbara, Chihuahua, Mexico; the Inspiration Copper Co., at Globe, Arizona; the Mason Valley Mines Co., Yerington, Nevada. Mr. Thompson is enthusiastic over the prospects throughout the West and Southwest.

MEXICO.

Power at Pachuca.— Hostotipaquillo.Mines Active. — Naica.

Rapid growth of the mining companies operating in the Pachuca district, and the far greater expansion which the near future will undoubtedly witness, have necessitated arrangements for immediate increase of power. The Compañia Electrica é Irrigadora of Pachuca, the present supplier of electric power to the camp, has available some 12,000 hp. only, which is generated in their hydraulic plant near Pachuca. While this is more than enough for the plants at present in operation, it will not be sufficient when the new plants are completed. The Mexican Power & Light Co., which draws its power from Necaxa, is putting in transmission lines from Mexico to Pachuca and hopes to complete them by July. The Compañia Electrica é Irrigadora has entered into a working agreement with the Necaxa company. It is probable, however, that some of the new companies will put in gas-power plants, as is contemplated by the Santa Gertrúdis company, as such power supply has been demonstrated to be cheaper and more reliable for large plants than an independent electric supply. The Hacienda San Francisco at Pachuca which has only recently completed the installation of twenty stamps, is now preparing to add another twenty, together with concentration plant, re-grinding mills, and cyanide annex. The latter will consist of three large Pachuca agitation tanks and a Moore vacuum filter plant. The new Guadalupe 300-ton plant of the Santa Gertrúdis company has just started, but only with part of the plant, owing to an accident to one of the re-grinding mills. It is expected that it soon will be running at capacity. The mills operating in the district are now daily crushing about 1500 tons.

An important silver mining district of Mexico which is only now beginning to receive deserved attention, is that of Hostotipaquillo. The mines of this camp were worked originally by the Spaniards and later by Mexicans, but only to a small extent and superficially. The main reasons for them not attracting greater attention were the isolation and the cost of freight. There was also difficulty in treating the ores economically. The new Southern Pacific railway extension from Guadalajara now brings railway facilities within three hours by a wagon-road from the town, and a private electric railroad from Magdalena to Hostotipaquillo will soon give the camp still cheaper rates. In addition, the transmission of electric power from Guadalajara to Hostotipaquillo, which is now nearly completed, will give the mines cheap power and facilities for working upon a larger scale. The cyanidation of ores, after a preliminary concentration, has proved an efficient treatment. Previously non-payable ores containing 400 to 500 gm. silver per ton can now be treated at a good profit. The effect of these improvements has been a renewed interest in the district, and considerable inflow of capital for development. Several of these mines have treatment plants, and await the completion of the electric power-lines to commence crushing. The most important producers to date have been the Buena Vista mines to the north of the Santiago river, and which alone have shipped bullion worth about ₱4,000,000, the Castellana mines, situated about 20 miles to the northwest, which have a 50-ton mill and cyanidation plant, and the El Favor Mining Co., which now has a

150-ton mill and cyanidation plant awaiting electric power. The last named company has a large tonnage of low-grade ore blocked that can be treated by cyanidation at profit. The Castellana mines, at present closed for development and electric power, have produced large amounts of rich ore from Spanish times to the present. Among the properties being developed at present are the Santa Domingo mines, Cinco Minas, La Dicha Mining Co., the Mala Noche mines, the Ventana mines, the Quebradilla mines, and others. The veins of the district are strong fissures, varying in width from 2 to 6 metres, and yielding good ore in depth. They have a general northwest strike and traverse andesite. The ores are quartz carrying iron and copper pyrite and a considerable percentage of manganese oxides with which the silver is partly associated. The whole district is well mineralized, and promises to become in the near future an important silver-producing district. The gold associated with the silver in the ores varies from 1.5 gm. per kilogram of silver in the Castellana mines, to 12 gm. per kilogram of silver in the Buena Vista mines.

The Compañia Minera de Naica, owning the Dolores, San Francisco, Toleda, and other silver properties at Naica, State of Chihuahua, have just given their mines under option for $6,000,000 to Americans. These properties have been paying good dividends for many years, and the shares worth $300 at par, reached as much as $30,000 on the

Part of Jalisco, Mexico.

market some time ago. The capital of the present company is only $30,000. The San Carlos gold mine, situated in the extreme southwest corner of the State of Zacatecas, is starting its mill and cynidation plant, after four years of inactivity. During this time the mines have been under development, and have now a large tonnage of pay ore blocked. The mines paid good dividends in 1901, 1902, and 1903, but were closed in 1906 for lack of sufficient ore. The company (English) was then re-organized and development undertaken. This has turned out well. The plant, which consists of a 50-stamp mill with cyanidation annex, has been repaired and will commence crushing in a few days. It has a capacity of about 4000 tons per month. Mining business in general is greatly improving in Mexico, and new enterprises are being undertaken. The successful application of the cyanide process in the economical treatment of silver ores in Guanajuato and Pachuca, coupled with better financial conditions, is creating renewed interest in silver mines that under old methods would not pay to work. Two new plants are being erected in Zacatecas, one of which, a modern cyanide plant with a capacity of 70 tons per day, will treat solely the old tailing from the famous Veta Grande mines. The same causes which have so greatly increased the activity in the larger camps of Pachuca, Guanajuato, and Zacatecas, are gradually being felt in other districts of the Republic.

GOLDFIELD, NEVADA.

Combination Fraction.—Clermont Workings.—Florence Goldfield.

Of recent developments the most noteworthy have been discoveries of excellent bodies of milling ore at two widely separated points in the Combination Fraction mine. On the 285-ft. level the ore has been exposed near the old stopes and near the point where a good grade of product was mined formerly. The ground here is unstable, and, owing to the fact that the proper mapping of the early workings was neglected and much of the stoped area has caved, further driving on this level will be abandoned as unsafe and the orebody will be developed by driving back from the extension of the 300-ft. level. The more promising of the two new discoveries is at a depth of 500 ft. in territory heretofore unexplored, northeast of the shaft and directly on the strike of one of the richest Mohawk ore-shoots. The ore was cut through diagonally and is apparently 15 ft. across with an average gold content above $30 per ton. A station has been cut at the 750-ft. level which will at once be driven to connect with the 750 drifts from the Clermont workings of the Consolidated. By the terms of an agreement existing between the Consolidated and Combination Fraction companies any possible disputes over apex rights are eliminated and each is entitled to the ore lying within its vertical boundaries. Conditions on the 1000-ft. level of the Clermont are highly gratifying. The orebody is shown to be of large proportions, excelling even, in marked degree, the excellent showing on the 900. Another recent development that is regarded as highly important is the opening of the main Mohawk ore-shoot on the 750-ft. level, and 150 ft. west of the Clermont orebody at that depth. The cross-cut passed through 8 ft. of milling ore, averaging about $30 per ton. Production from the Clermont has been increased and this shaft will ultimately be the avenue of output for at least one-half the product of these mines.

The Florence is breaking a comparatively small tonnage at present for the reason that a sufficient quantity of ore had been stored in the Little-Florence stopes to supply the mill during the period while the work of enlarging the main shaft from the 500-ft. level is in progress. This work was not begun until there was ample assurance that no delay or shortage could be occasioned and that the supply, conveyed from the Little-Florence shaft over the aerial tramway, was adequate for all requirements. On the Diamondfield Black Butte a cross-cut from the original company adit on the north of the hill has penetrated the ore-shoot opened farther east by lessees who have made several shipments. The old company shaft is being unwatered and from it a cross-cut will be driven to tap the vein 200 ft. below the adit level. The Grizzly Bear shaft is down 1050 ft. and a station is being cut at the 1020-ft. level from which the lessees will drive to the west for the Mohawk ore-shoot. Three shifts are working, employing machine-drills, and a new 75-hp. hoist has been installed. Some ore of excellent quality is being saved on the Nancy Donaldson where the drift on the 125-ft. level has been following a narrow vein containing seams of high grade. Assays from this vein in places have been as high as $500 per ton, and at several points the ore has widened to good dimensions. Ore taken from the croppings on the Nancy Donaldson has assayed above $3000 per ton, and the veins are unbroken and of good character.

Complete hoisting equipment has been ordered for the Queen shaft of the Queen Consolidated Mining Co., a merger of two organizations owning the Queen group, the Congo group, and a lease on the Atlanta where the original company shaft is being sunk to a depth of 750 ft. At present seven leases are operating on the Atlanta. On the Grizzly Bear claim of the Jumbo group the Grizzly Bear lease has cut a station at a depth of 1020 ft., and has started a cross-cut to the west in search of the Mohawk vein. The Annex lease on the Polverde is driving on the vein east and west at the 800-ft. level, and a raise from this level is following the shoot. Ore-bins have been installed, skip-pockets and a large station cut at the 800, and a 6-drill compressor is in operation.

FAIRBANKS, ALASKA.

Quartz Mining. — Pioneer Mine Leased. — Spaulding Ships. — Willow Creek Discovery.— Custom Mill Planned. — Placers Active.—Cleary Creek. — Little Eldorado. — Bonnifield District.—Circle.— Chandlar River. — Koyukuk. — Haiditarod.

Recent developments made by certain quartz properties have tended to increase interest. Reaction from the tunnel-site boom of last winter left the industry practically stranded, but faithful workers have shown this district to be promising. This winter there are more men engaged in development of prospects than ever before, and reports are uniformly encouraging. On Dome creek, W. S. Spaulding has mined several tons for a mill-test to be made at Fairbanks. His property is opposite No. 10 Above Discovery placer claim. The Pioneer Quartz Mining Co., which was first seriously to attempt development in this vicinity, has leased its property. The mine is on Chatham creek. A strong vein assaying well was followed down over 100 ft. before the mine was flooded a year ago. Since then, an adit has been driven for 150 ft., but was discontinued before the vein was found. No active work has been done lately on the Jupiter-Mars property, between Wolf and Chatham creeks. Mill-tests on rock from prospect holes sunk last year show $21 per ton in free gold. Samples from a stringer near the main vein recently gave assays of $146 per ton. The first full carload of ore shipped into Fairbanks arrived late in February. The shipment consisted of about 20 tons of rock sacked at the Spaulding property, at the head of Dome creek. Interest in this run and in quartz in general has grown since returns from the 5-ton shipment of ore to the Rush smelter at Tacoma were found to give $460 per ton. This shipment was from the Rhodes & Hall property, on Bedrock creek, and proves the assertion that the wall-rock on both sides of this lode will give a profit for milling. Cascaden & Crawford have a lease on a block of ground 100 by 50 ft. in the tunnel of the Rhodes & Hall property, and have a large amount of ore broken and sacked. The Tolovana Mining Co. is active. Its vein opened on Bedrock creek has proved to be high-grade, and a late discovery across the ridge bordering Willow creek shows high-grade rock carrying a large amount of free gold. A sample picked from a sack of ore sent into town with the intention of getting a minimum assay, gave returns at the Tanana assay office of $475 per ton. The owners feel that in this block of claims they have a valuable property. Drill-holes on the Bedrock claim have shown several lodes, hitherto uncovered, that assay well. Charles Crawford, holding a lease on the Tolovana Mining Co.'s lode on Bedrock creek, has now a 150-ft. tunnel in on the vein with a winze over 50 ft. deep at the end. In the winze water was struck and work temporarily abandoned. It exposed ore all the way, thus blocking out a large amount of high-grade rock. One hundred feet of backs in the tunnel are also available. Herchberger and partners now have a 4-ft. vein of rock that assays well. As far as development has gone the vein continues strong between well defined walls. Jackson and partners on the summit between Cleary and Fairbanks, have developed a vein of quartz that averages 2½ ft. wide. Though no assays have been made, the rock pans well and is similar to that of the Rhodes vein on Bedrock creek. Perhaps the best indication of faith in Tanana quartz is shown by the well founded rumor that a 10-stamp custom mill is to be built at Chena, eight miles below Fairbanks. It is understood that Falcon Joslin, president of the Tanana Valley railroad, plans this, and also to erect a plant to supply power for electric locomotives. Two new locomotives are to be brought in next summer. By extending the line up Pedro and Cleary creeks, the centre of the quartz district could be tapped and cheap transportation afforded.

Competent judges agree that more gold will be produced this season from the placers than last. A large amount of good pay is now on top in the winter dumps, while there will be work for probably 600 men this summer. Seventeen Goldstream and the adjoining Owl Association will be big producers. Cleary creek will easily be the banner producer this summer. Seven outfits are working on No. 4 and 5 Below, taking out dumps and preparing for summer work. This ground has long been closed by litigation. A quarter of a million dollars has been taken out this winter by two outfits on Ready Bullion, a tributary of Esther creek. Badoin & Lynn sluiced nearly all winter keeping steam-pipes in the boxes. Thirty shovelers were employed and the weekly clean-up was $10,000 to $15,000. They have now discontinued operations as their block of ground is worked out. In the Badoin & Lynn lease and the Gardner lease pay was found to stop at a big 40-ft. vein. As the gold is rough and full of quartz, it is probable this is the chief source of pay. The head of Little Eldorado is showing well at present. Thompson, Scrafford & Geis have an 8 by 8-ft. shaft down on a large vein. A cross-cut has been driven at the bottom of this and samples sent to the First National Bank assay office show a 20-ft. face averaging about $20 per ton. Mr. Thompson has found another vein farther up Skoogy gulch that pans well, but from which no samples for assay have been taken. A rich stringer extensively prospected last summer, is still being exploited by Lawson & Sommersett. This vein is on the divide between Fairbanks creek and Cleary creek. Rich specimens were brought in last summer. Dan McCarty is still working on his property on Wolf creek, the next tributary of Cleary on the right limit below Chatham. The vein shows good ore and developing has opened up a big body.

Mining at Fairbanks.

A lot of prospecting was done in the Bonnifield district last summer. The veins seem to be larger and lower grade than those near Fairbanks and contain a smaller percentage of free gold. On the big Jerome Ledge, owned by Crawford, McConnel & Chute, of Fairbanks, a small 3-stamp test-mill was placed last spring. Rock was taken along the 600-ft. face for the test and yielded $3 per ton free gold on the plates. Tailing brought to Fairbanks and tested at the Tanana assay office showed a total content of $5 per ton. It was found that a good extraction could be obtained with cyanide. The minerals appear in a finely divided state, explaining why rock was crushed through 40-mesh screens before any free gold was caught on the plates. The mine is a mountain of quartzose rock, a 600-ft. face being exposed by the creek. Seven miles below, Arthur Cruger has staked a 3 to 6-ft. vein yielding returns of 3.5% copper from the croppings. The vein is schist with small quartz stringers, apparently more copper being contained in the schist than in the quartz. The Berry hydraulic operations

on Eagle and Mastodon creeks, in the Circle district, seem to have made a good showing during the last summer's sluicing. Giants were used on these properties in a novel and singularly efficient manner. Water being plentiful and the grade of the creeks being slight, not only is the gravel piped up an incline into the boxes, but the tailing is subsequently stacked by another nozzle. A foot or two of bedrock is taken up with the gravel. Captain Haynes and party left Fairbanks the second week of February for the upper Chandlar river. With him is the freighting outfit which is taking his 3-stamp mill to Circle. From there on, the mill will be taken by dog-team to certain promising quartz prospects. The mill is a 3-stamp prospecting mill, the stamps weighing 250 lb. Another small mill, one of four stamps, is being taken into the Chandlar by S. J. Marsh. This plant includes a rock-breaker, ore-feeders, and two 2-stamp batteries of 750-lb. stamps. Some of the quartz veins in the Chandlar district are as much as 12 miles above timber line. Last year only 70 hours water was available for sluicing, the camp being far north and the season short. In that time, however, $11,000 was washed out of soil and crushed rock that had sloughed from the outcrop of a quartz vein. Wash gravel is practically unknown, most of the erosion being effected by shattering of rocks by frost.

Recent letters from the Koyukuk tell of rich finds being made on tributaries of Hammond river. One hundred and thirty pans netted $1500 for Joe Healey, while Shook and partners have panned and rocked out $5000 after being a month on bedrock. Frank Decker has exhibited a small baking-powder can of nuggets at the company store that he claims to have picked up from his dump in one day. It is probable that a mild stampede will ensue this summer to the Koyukuk diggings. Although the telegrams from the Halditarod tell of four miles of pay on Flat creek, reliable prospectors who have visited the country contend that Flat creek is only three miles long from summit of ridge to mouth. The most conservative people still doubt that the Halditarod stampede was justified by anything except paper arguments and are loath to believe these late telegrams.

LONDON.

Ashanti Goldfields. — Tin in Burma. — Mexican Properties. — Midas Deep Scandal and Homersham's Report.

Attention of investors has been attracted once more to West Africa by the formation of a new company called the Ashanti Goldfields Territories. This has been formed by the Ashanti Goldfields Corporation for the purpose of acquiring mining rights over a tract of country of 100 sq. mi., in fact, the whole of the Corporation's property, with the exception of the seven or eight miles of ground already developed. The object of the new company will be to systematically explore this tract. The territory is known to contain many gold-bearing deposits and outcrops of rock similar to that found at the mines. The work will be done under the direction and advice of W. R. Feldtmann, and the manager will be J. N. Justice. That the latter has been successful as a developer and discoverer may be seen from the fact that one of the large orebodies belonging to the Ashanti Goldfields Corporation is known as Justice's Find. Another event in connection with the West African market has been the issue of 100,000 new shares in Prestea Block A. This company owns a large quartz deposit at Prestea, and, pending the completion of railway communication, operations are being centered on development and extension of plant. The report of the engineer, Walter Broadbridge, for the year 1909 has been published in advance of the director's report and balance sheet, in order that shareholders may have information at as early a date as possible, and thoroughly understand the reasons for a proposed issue of new capital. Since the end of July milling has been suspended and work concentrated on development and the provision of new plant. During the first seven months of the year 49,305 tons of ore was treated yielding 15,203 oz. in the battery, 2315 oz. in the cyanide plant, and 2009 oz. from concentrate; a total of 19,537 oz. valued at £82,996 or 33s. 7d. per ton. The ore reserve above the fifth level on December 30 was 500,014 tons containing 9.96 dwt. per ton. Arrangements have been completed for the provision of new machinery. Fifty new stamps are to be provided, bringing the total to 110. Electric power is being adopted and new pumps are required. The total cost of the outlay on plant will be £90,000, and a similar amount will be required for development and construction work at the mine. The company has in hand a sum of £72,000 and they propose to create 100,000 new shares and offer them to shareholders at 27s. 6d. per share. The whole of this issue has been underwritten by Wernher, Beit & Co., the West African Mines, Ltd. (representing the Consolidated Gold Fields of South Africa), and the Fanti Consolidated and the United Exploration (both promoting companies belonging to the previous controllers of the Prestea Block A).

The mining has been attracting attention in London recently, especially in connection with Nigeria, and the Shan States in Burma, adjoining China and Siam. Southern China has been known as a tin-producer for many years, but apparently little has been done in the Shan States. The Mawchi deposits were brought to the notice of English investors by W. B. Dick a year ago, and have been since partly developed. The company operating the property is called the Southern Shan States Syndicate. C. M. Euan Smith is the engineer in charge, and Norton Griffiths, Bruce Marriott & Co., are the consulting engineers. The capital is £150,000, of which £74,000 in shares went as purchase price, and 14,963 shares have been issued for cash and 10s. paid on each. The directors are now issuing 20,000 more shares and published a prospectus at the end of February. The report of Mr. Euan Smith accompanying the prospectus shows that the property is situated on the side of a steep hill. It contains a number of veins in the granite and is covered with tin-bearing gravel. The latter has been prospected by means of sampling pits. The depth of the pits average 9 ft. It is estimated that there is 475,944 cu. yd. of profitable gravel ready for treatment. The content varies within wide limits, the samples giving results from 2 lb. to 91 lb. black tin. Three-quarters of the gravel is estimated to average 6 lb., and the other quarter 2 lb. The cost of treatment with the present resources is 4½d. per cu. yd., but with a water-supply that can be brought from a spot 2½ miles away, the cost of sluicing could be reduced. The exploration of the underlying granite has been started at several points with some success. The sampling of the veins shows extensive deposits of varying content. Money is now being subscribed for systematic development. N. B. Knox has been sent to Burma to make an examination. There are some veins of galena on the property belonging to the syndicate; these also will be investigated by Mr. Knox.

The investing public has been treated to a Mexican antigua this week, by the publication of the prospectus of the Esmeralda Consolidated Mines, Ltd. The properties actually acquired are the old Guadalupe and Cocina silver-lead mines in the district of Iguana, Nuevo Leon. They are not far from an even more notable producer of days gone-by, the Voladora. Adjoining claims that are undeveloped have also been acquired by the company. These are called the Esmeralda property and give the company its name; but it is the two old mines and the old dump which are to be the centre of active operations. The estimated resources at the Guadalupe are stated to be a million tons, averaging 30 oz. silver and 18% lead, though no detailed account is given of the veins or of the method of sampling. The mine is said to contain also argentiferous blende. The dump is reported to contain 330,000 tons averaging 20 oz. silver and 10% lead. Some of the mining papers here speak well of the promotion, but to those who know Mexico, the affair is not quite so convincing. If the promoters were sure of their figures relating to the ore reserves, the capital of the company would never be fixed at the absurdly low figure of £150,000.

About a year ago there was some considerable scandal in South Africa in connection with the booming of the shares of Midas Deep. Extraordinarily high assays were published, and the shares bounded up. Subsequently the mill closed owing to the poverty of the ore. At the time little

definite information was available, and it is only now that an authoritative statement has been made by the directors. It is worth while giving some details, if only to show that the Rand is not entirely the humdrum centre of legitimate industry that is commonly supposed. The mine is situated at the extreme west of the Rand, beyond and to the south of the Randfontein group, and 20 miles from Johannesburg. It was originally floated in 1895 by the Consolidated Gold Fields and others, and milling was started in 1896, but only continued for 18 months, as the ore became gradually lower in grade. In 1904 additional property was acquired. E. H. A. Cohen, who had been in charge before the mine was closed in 1897, was appointed to supervise the re-opening in 1908. A year ago the directors announced sensational assays of ground recently developed, and as a matter of fact the directors had received even higher figures than those published. The chairman now states that some of the suppressed assays showed £7000 of gold per ton, which they had the good sense to discard. Mr. Cohen's engagement terminated last June, and Samuel Roberts has been in charge since. The mill started operations at the end of March and continued until the end of September, when the grade of ore was found to be too low to pay expenses. During this period 20,776 tons was milled and produced 1956 oz. gold by amalgamation, and 12,285 tons were cyanided yielding 1776 oz., a total of 3732 oz. valued at £15,-698. The situation was so serious that Edward C. Homersham, of Randfontein Estates, was asked to examine and report. He found that the 'Black Reef' on which the work had been done was narrow and of low grade. For instance, at one place the lode was 3 in. wide, and assayed 36 dwt., and at another point 1 dwt. over 30 in. One of the stopes was found to average 3.3 dwt. over 30 in., and occasionally gave samples running 90 dwt. for an inch or two. It becomes clear from this statement that Mr. Cohen was able to report high assays, in spite of the fact that the average was poor and the extent of the ore limited. Mr. Homersham proceeded to make a general geological examination of the ground, with the object of locating the Randfontein series, and diamond-drilling has been undertaken. In the meantime the scandal connected with the inflation and collapse had received the attention of the Transvaal Government and their commissioner had made an examination of the mine. His report has not been published, but his conclusions are the same as Mr. Homersham's. The directors urged the Government to make a searching investigation into the share transactions which took place while the sensational assays were being published, but the Government objected that the legal proceedings involved in such a course would be too lengthy and costly. This is a pity, for enlightenment on the subject as to who was reaping profits in this underhand manner would have been good for the mining industry.

BRITISH COLUMBIA.

Zinc Problem Again. — Early Agitation. — Zinc Commission. — Attempted Smelting.—Proposed Experiments.—Zinc Mines.

The recent authorization by the Canadian Parliament of an expenditure of $50,000 in experiments by the Dominion Department of Mines on processes for the reduction of zinc ores recalls previous efforts to solve these problems. Early in 1904 an organization, consisting chiefly of owners and managers of mines situated in Slocan district, known as the Associated Silver-Lead Mines of British Columbia, instructed its special committee to memorialize the Dominion Government to engage a high authority on zinc and its treatment to investigate and report on the zinc ores of the Kootenay district. This proposal was endorsed by the Associated Boards of Trade of Eastern British Columbia. In connection with this movement, A. C. Garde, the resident manager for the Payne Consolidated Mining Co., owning the Payne mine, near Sandon, Slocan district, prepared and published a strong statement outlining the benefits to be derived from fully investigating the resources of British Columbia as to their extent, value, and character, and giving much information relative to the occurrence of zinc in association with silver-lead ores in mines in Slocan district. An important consideration brought out was that, apart from their silver content, the zinc ores of British Columbia were worth mining for the zinc in them alone. It was believed that there exists in the Province an unlimited quantity of zinc ores suitable for both spelter and zinc-oxide production. Zinc smelters in both the United States and Europe had already awakened to the potentialities of the industry of the Province, and as a result zinc ores were being exported to foreign countries to be manufactured into spelter and zinc oxide. That meant that Canada first paid freight on the raw material taken out of the country and afterward paid freight and duty on the manufactured products imported. It was estimated that Canada in that way paid more than 2c. per pound on all spelter it used and proportionately on other zinc finished products.

As a result of the representations made from British Columbia, the Dominion Government in the summer of 1905 appointed W. R. Ingalls, of New York, "to make an investigation of the zinc resources of British Columbia and their commercial possibilities", and designated Philip

A Portion of British Columbia.

Argall, of Denver, Colorado, and A. C. Garde, of Sandon, British Columbia, as his assistants, with Henry E. Wood, of Denver, to investigate the adaptability of the ores to magnetic and electrostatic concentration. The report of this Commission contained between 300 and 400 pages. In the introductory chapter Mr. Ingalls dealt with the history of zinc mining and smelting in the West, statistics of production, character of the ores, markets for ores, valuation of zinc ores, cost of smelting, value of argentiferous blende, and wet processes of zinc extraction. Other chapters gave much detailed information relative to the zinc mines and undeveloped zinc resources of British Columbia, methods for concentration, assaying, and other subjects.

Despite this report no considerable progress toward the placing of the zinc mining industry on a permanent basis in British Columbia has yet been made. Much money was spent by one company operating mines in the Ainsworth and Slocan mining divisions, in erection and equipment of works designed to produce spelter, but commercially these were a failure. Other works were afterward built at Nelson and equipped for treatment of complex lead-zinc ores by an electro-thermic process, but here again results were unsatisfactory and operations were not continued. Meanwhile a duty was placed on zinc ores entering the United States, so those interested in the mines in Ainsworth and Slocan district held a meeting at Nelson, last December, and petitioned the Dominion Government to take the steps necessary to establish a smelting plant capable of treating

Canadian zinc ores and of producing manufactured products of zinc, at least to the extent of supplying the Canadian market. Especially it was asked that the Dominion Department of Mines be authorized to take up the matter and conduct experimental work upon such a scale as will determine definitely the practicability of the economical treatment of zinc ores by electro-thermic or electro-chemical process. On March 21 the House of Commons provided for the expenditure of $50,000 for the purpose of investigating the processes in use in the production of zinc, and for experiments in manufacture of spelter and other zinc products from Canadian zinc ores. It is understood the experiments will be made at Nelson, probably at the works in existence there and at which much experimental work has already been done.

In conclusion, it may be mentioned that last year zinc ore and concentrate containing about 11,000,000 lb. of spelter was shipped from mines in Ainsworth and Slocan divisions. The Lucky Jim mine shipped to the United States about 5000 tons of ore averaging about 52% Zn, while the Whitewater, Ruth, and Van Roi shipped concentrate running about 45% zinc.

JOHANNESBURG, TRANSVAAL.

A Manager's Opinions.—Administrative Questions of the Day.—Influence of Monthly Returns.—Costs per Ton Milled.

It is not often that the retiring president of the Association of Mine Managers delivers a valedictory address of the comprehensiveness marking that of P. Cazalet at the fifteenth annual meeting held on February 18. The ground was so fully covered (in a speech amounting to seven newspaper columns) and the affairs dealt with of such topical interest, that this letter will be devoted to a discussion of Mr. Cazalet's retrospective and prospective survey of technical events and tendencies. Apart from the native labor question—which is apt to be wearisome to readers in other lands, but in its present treatment was enlivened by a bold expression of regret concerning the re-patriation of the Chinese, the chief points raised were the following: (1) the mining regulations; (2) mine managers' examinations; (3) publication of statistics; (4) the 'bogey' of low costs per ton milled; (5) theft of gold; (6) training of white labor; and (7) contract and day's pay work underground.

The first three points have already been discussed at length in these columns, and on No. 1 and 2 opinions similar to those voiced by Mr. Cazalet have been expressed. There is undoubtedly a tendency to make the mining regulations too voluminous and too detailed, by attempting to introduce special provisions to meet all contingencies instead of relying upon general provisions. The necessity for changing the system of mine managers' examinations was mentioned in this correspondence twelve months ago, when W. W. Mein, the preceding president of the Association, expressed his dissatisfaction with the strange incongruities of examination results. Lately there have been many more men passing and the standard of papers has been found much better. Of course, the simplification process could be overdone.

In the matter of publication of statistics Mr. Cazalet takes a standpoint entirely opposed to mine. He pleads, in support of L. Reyersbach's proposal, for the non-publication of monthly returns and statistics, and attempts to justify this policy by suggesting that the erratic yields following a scheme of extreme concentration and of working the mine for the utmost gain, irrespective of 'regular' grade, would have excellent effects, if only annual results were made known. He says: "Carry out the policy of concentration and the grade in the erratic mines will almost inevitably vary from 1 to 2 dwt. in recovery in different months of the year. Where results are published monthly and regularity is looked for, the inevitable safeguard is the one so largely employed on the Rand—namely that of scattering the laborers in comparatively small working faces over long distances and it follows that some of that maximum profit, which is the ambition of the members of this association, is frittered away in the effort at regularity of output." Mr. Cazalet's honest enthusiasm leads him to an exaggerated view. In the first place, it is a daring assumption to state that the yield is likely to jump about to the extent of $1 to $2 per ton each month (say 15 to 30%) at any modern mine of big capacity. A mine requiring to put out, say, 2000 stope tons per day of two shifts will require 30 to 40 stope faces at least, however much they may be concentrated and forced at high pressure. These are most unlikely to vary more seriously than by an amount readily and legitimately adjusted by regulation of clean-ups and gold reserve, or by occasionally forcing or limiting the output from some of these 40 stope faces. Furthermore, Mr. Cazalet is in error when he states that efforts are wasted in order to attain "regularity of output." It is fair regularity of such profit as is consistent with the showing of payable ore reserves that is sought—not regularity of output. So that present supposed requirements tend to check managers from "flying about from one stope to another to obtain regular monthly returns." That is not the way to maintain regular costs at all events. As Mr. Cazalet says, it is not his concern that non-publication of returns may create distrust with investors. But recognizing the danger of doing this, it is unquestionably the duty of the manager to see if he cannot still obtain the best economic results from his mine without causing uneasiness over fluctuating returns. It is another case of where there is a lot of talk and little achievement. Rand investors are already used to fluctuations in monthly profits, and if a drop for a month or two does not cause a panic (when they are supposed to understand that the manager has been scrambling round the mine for tit-bits of rich ore to prevent the fall), why should they feel nervous if they—namely, the investors in a few mines chosen for the scheme—are plainly told that the policy of equalization has been stopped and that the results for one month give no promise of equally good or bad ores in the next. Why cannot a manager and sympathetic board get to work on the scheme and show the good results to be obtained in a year, and the extent of the variations in profit to be expected? Let the monthly returns go on as usual, and let directors and managers rest assured that the ill consequences of publishing no figures at all would be infinitely worse than announcing fluctuating results following such an explanation and promising to total satisfactorily over a long period.

Of the 'bogey' of low costs per ton milled, more is likely to be heard later. The present system is liable to abuses, when the cost per ton milled is taken as the basis of comparison between the work of different mines or managers. By taking cost per fathom or any other unit of square measurement on the plane of the reef, there will be less inducement for the "ambitious manager to allow excessive stope widths to be carried on and to slight sorting." The square fathom is, however, a useless unit outside the mine, and the ton must still reign in most departments. Thus it is reasonable to suppose that the two standards would have to be used in parallel. There is one serious drawback (among many) that Mr. Cazalet failed to notice in his vigorous denunciation of the cost per ton 'bogey'. The new system would be open to as many and as serious abuses and would call for constant investigation and control as the present. A mine might be badly run and yet look well on the cost and immediate profit per fathom basis; for the less profitable bands of 'reef' might be left in foot-wall or hanging, and probably be entirely lost upon the caving of the ground. As to gold thefts, Mr. Cazalet deprecates wholesale accusations and vague generalizations, but evidently thinks the matter should be more adequately investigated. The importance of a more general all round mining training for white youths was forcibly and ably expressed. Mr. Cazalet pointed out the unfortunate thing that far too many of the skilled white labor recruits immediately apply themselves to machine-drilling and that only for the reason that machine contractors are the highest paid. The contract system was condemned mercilessly. Day's pay with a good living wage plus bonus was strongly advocated. He pointed out, however, that the change of practice could not be brought about by one mine or group of mines, but only by concerted action.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Cochise Gold Mining & Milling Co. has been organized to open a group of claims on Steel hill 20 miles northeast of Benson. The shaft now down 60 ft. will be sunk to the 100-ft. level and the vein cross-cut.

GILA COUNTY.

(Special Correspondence).—The Inspiration Copper Co. is about to erect a small experimental mill for making tests of its low-grade ore, preparatory to building a large concentrator. On and above the 400-ft. level of the Joe Bush shaft, 3000 ft. of drifts and raises have been completed. The cross-cut driven south from the Scorpion shaft is 360 ft. long and is continning in ore. Before production begins, a new shaft, having at least four compartments, will be sunk about 1300 ft. south of the Joe Bush shaft and the ore mined by the mill-hole method.——The upper sub-levels of the Miami mine, above the 420-ft. extraction level, are now almost wholly blocked out, and much work is being done where tracks for motor cars are being put in. Preparations for building large ore-pockets on this level are also under way. Five churn-drill holes put down on the Captain claim have struck a body of ore apparently of considerable magnitude, which is believed to be an extension of the Inspiration orebody.——The churn-drill ordered for prospect work on the property of the Cactus Copper Co. is expected to arrive at the mine soon.——The estimated production of the Superior & Boston mine during March is 2250 tons of ore averaging 9% copper and containing nearly enough silver to meet smelting charges. It is expected that the output of copper for this month will be 500,000 lb. The method of stoping without timbering recently adopted is proving successful. J. D. Wanvig is superintendent.——Several directors and heavily interested stockholders of the Globe Mining Co. have visited Globe recently, and in company with J. F. Hechtman, president of the company, have inspected the property with a view to outlining future operations and directing the purchase of machinery for continuing the work. The resumption of sinking the vertical shaft from its present depth of 415 ft. is being contemplated, and a larger hoisting plant will be installed.——At its present depth of 620 ft. the Williams shaft of the National Mining Exploration property is in copper-stained quartzite.——The second churn-drill hole sunk on the property of the Cordova Copper Co. is 523 ft. deep and has passed through 100 ft. of low-grade suiphide ore.

Globe, March 26.

GRAHAM COUNTY.

The Cobre Grande group of claims 23 miles west of Fort Thomas in the Santa Teressa mountains has been sold for $100,000 to Albert F. S. Cooper, representing the firm of Wheeler & Shaw, of Boston. There are 14 claims in the group, and the payments are to be distributed over a period of two years. A number of open-cuts and adits have opened ore averaging 5% copper. The new owners will install machinery and commence sinking at once under the supervision of Mr. Cooper.

MOHAVE COUNTY.

Mineral Park, one of the oldest mining camps and second county seat of Mohave, is active again after years of practical desertion of all but its turquois mines. At the Keystone, one of the largest of the old-time producers of gold and silver, which is now under bond to a Los Angeles company, the new equipment consisting of a 100-hp. boiler, 50-hp. hoist, air-compressors, and electric generator has arrived and is being installed. The main shaft has been retimbered and a new head-frame completed. Work on water and oil tanks of 11,000 gal. capacity each is also well under way. The vein is from 6 to 40 ft. wide, and outcrops for over 5000 ft. Its ores are the usual lead, zinc, copper, and iron sulphides of the Cerbat range and assay well in gold and silver. S. R. Porter is superintendent.——The Venture Exploration Co., of Duluth, for which J. P. Hamilton is superintendent, is sinking a new shaft on the Oneida near Stockton hill. A larger hoist has been installed and the shaft will be sunk 400 ft. before cutting stations.——The sale of the Dandy mine, in the Weaver district, by William Hall to J. P. Hutchinson, of Chicago, has been completed. Mr. Hutchinson proposes to continue the present 230-ft. shaft to a depth of 500 ft., and to begin at once the erection of a 20-stamp mill and cyanide plant. There are about 10,000 tons of ore averaging $15 per ton in free milling gold blocked out in the mine.——The Redemption Copper Co. has resumed work on its new concentrating mill and it is expected to be in operation by May 1. R. J. Ferguson is superintendent.

YAVAPAI COUNTY.

The shaft at the Golden Idol claim of the Hillside Consolidated Mines Co., operating in the Cherrk Creek district, is now down 155 ft. and the mill is being run on the ore from the 100-ft. level. The company is to commence work on the Hillside and adjoining claims shortly. W. D. Achauer is superintendent. The cross-cut on the 800-ft. level of the United Verde Extension property near Jerome opened an 8-ft. orebody recently.——J. H. Morrison, superintendent for the United Gold Mines Co., at Congress, has been running the new mill about half the time, as the cyanide plant was not large enough to handle the pulp from a continuous run. An addition has been started to the plant and it is expected to have the mill running at its full capacity in the near future.——The Seth Bullock Mining Co. has purchased a group of five claims in the Cottonwood district from Srapp & Whithouse.

CALIFORNIA.

CALAVERAS COUNTY.

Operations have been resumed at the Washington mine near Sheep Ranch.——The drift at the Scossa mine in the Mountain Ranch district has opened a good shoot of ore.——At the Swank property development is being carried forward on a 5-ft. vein.——The shaft at the Martha property cut a shoot supposed to be the extension of that worked in the Ritter mine.——A $10,000 pocket was opened recently at the Finnegan mine, three miles from Angels Camp.——Work has been resumed at the old Pettlcoat mine at Railroad Flat under the management of Joseph King.

NEVADA COUNTY.

Work is to be resumed on the 20-stamp mill at the Fairview mine in the Washington district early this month. Underground work has been continued throughout the winter and considerable ore blocked out. C. M. Wilson is manager.——A raise has been started from the bedrock adit at the Blue Lead mine near Washington to open the channel. There are 640 acres in the company's holdings which extend for 9000 ft. along the channel.——The Ocean Star company has purchased 10 of the stamps in the Red Cross mill at Omega and will erect a mill at the Ocean Star property near Ormonde. The vein is about 6 ft. wide and the shoot 170 ft. long, assaying from $18 to $24 per ton. N. H. Truett is superintendent.——The Cassidy Consolidated Gold Mining Co. has been incorporated to open the Cassidy property that includes the ground between the Empire and Pennsylvania mines in Grass Valley district. An order for a 90-hp. hoist has been placed and the company will sink to the 1000-ft. level. The property has been worked to the 200-ft. level, but operations were suspended in the seventies on account of the heavy flow of water.——The North Star company has purchased the Tulle Belle group which adjoins its property. Very little work has been done on the group, though equipped with a small hoist.

PLACER COUNTY.

The adit at the Dewey mine at Foresthill is now in 300 ft. and will be driven 100 ft. farther to tap the shaft.——The Gold Blossom property is to be unwatered shortly.——Operations are to be resumed at the Crandall mine under the supervision of F. B. Norton.——Five stamps are dropping on good ore at the Orpheum mine and another five will soon be started.

SHASTA COUNTY.

(Special Correspondence).—It is announced that the

Afterthought Copper Co., which owns the Afterthought mines and smelter at Ingot, about 28 miles east of Redding will resume operations this spring. The properties have been idle since 1907 but it is understood that sufficient capital has been raised by a recent assessment to enable the company to resume. The copper content of the ore is from 6 to 12% with considerable gold and silver, and a high percentage of zinc. A. P. Flemming is president.——The Gladstone mine, operated by the Hazel Creek Gold Mining Co., is paying dividends of 1c. per month, a total disbursement of $9000.——It is reported that the Natomas Consolidated of California will install dredges on the upper Sacramento river this summer.

Redding, March 28.

The new 10-stamp mill at the Milkmaid mine near French Gulch has been completed and is crushing 35 tons of ore per day. The main adit is in 900 ft. and is expected to tap the old workings in a short time. The company is prospecting the ground with a diamond-drill.——Braynard & Kimball, of Redding, have secured an option on the old Potosi mine near Muletown for Eastern parties and work is to be resumed on the property.——A contract for 250 ft. of shaft work has been completed at the Reid mine in the Old Diggings district and an electric hoist will be installed that will elevate the ore to a place where it can be taken across the Sacramento river on an aerial tram.——A contract for 150 ft. of sinking has been let by the company which recently acquired the Evening Star mine.——The Mountain Copper Co. is installing a precipitating plant at the Hornet mine to treat the copper-bearing mine water.

SIERRA COUNTY.

A gasoline hoist is to be installed at the Sixteen-to-One property at Alleghany and a winze sunk on the vein.——The drift on the No. 6 level in the Sierra Buttes mine at Sierra City opened a shoot of high-grade ore thought to be the lower portion of the rich ore worked on the No. 4 level. Jay A. Folsom is superintendent.——It is reported that the old Mountain mine above Sierra City is to be reopened this spring.——The drift at the Standard mine in the Downieville district opened another shoot of high-grade ore and $5000 worth has been sacked for shipment.

TRINITY COUNTY.

(Special Correspondence).—Articles of incorporation have been filed in the county clerk's office by the Trinity Dredging Co., which has recently purchased quite a lot of gravel near the mouth of Eastman gulch on Trinity river above Lewiston. The incorporation was for $300,000, place of business, Chico, California; directors, E. L. Smith, of New York, W. J. Baker, A. S. Jones, H. E. Chesebro, and H. P. Durley, of Chico.——The recent find of coarse gold on the Blue Gravel placer mine on a branch of Summit creek in the Hay Fork mining district still continues to appear well, and from present indications points to a higher deposit than the present workings. The mine is being operated by T. J. Montgomery and E. Shock.——The Druitwater placer mine is being run by R. L. Duncan on a lease.——At Roker Bar, near Lowden's ranch on Trinity river, the company has several men at work getting ready to install an improved type of dredge with heavy machinery and intend to have it ready for operation by midsummer.——The Northern Headlight Quartz Mining Co. has a force of men at work getting ready to operate on a large scale. This property is being watched by mining men, as it is the first attempt to handle low-grade ore on a large scale in the Trinity Center district, and if it proves successful several other enterprises of the same kind will be started.

Weaverville, March 28.

Trinity County, California.

TUOLUMNE COUNTY.

The new mill at the Maddox mine near Confidence will be completed about the middle of the month. John Frey is manager.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—W. Farragher has resumed work on his lease on the 240-ft. level of the Astor mine near Georgetown. A shipment of four tons of ore made last week milled 440 oz. silver per ton. Stoping is in progress on a 4-in. streak.——Machinery is to be installed soon at the property of the Bard Creek Mining Co., operating a group of claims near the head of Bard creek. Compressor, boiler, and machine-drills will be purchased. Gus Nelson is manager.——Work has been resumed on the Silver Mountain property situated on Silver mountain.——B. J. O'Connell has started shipments of zinc from the east drift of the Gambetta mine to Denver ore buyers.——At the Stanley mine in the Idaho Springs district, operated by J. E. Bowden under lease, it is proposed to cross-cut the Stanley-Donaldson group of veins in a northwest direction from the bottom of the shaft workings. This zone is 2000 ft. wide and the cross-cut would open the vein system 800 ft. under the Newhouse workings, which are the deepest in the district.——A. Morelli & Co., leasing on the Blue Bird property, have uncovered a 10-in. streak of smelting ore in the adit that assays $35 per ton in gold and silver.

Idaho Springs, March 26.

GILPIN COUNTY.

(Special Correspondence).—A shipment of ore was made last week from the Milton mine in Enterprise district that assayed 433.2 oz. silver per ton and 13.5% lead.——A 2-ft. body of ore has been found on the 200-ft. level of the Iroquois mine in the Russell district that contains $40 per ton gold and silver. T. Dunstone is manager.——The Coeur d'Alene mine on Academy mountain has been taken under bond and lease by Chicago interests. The shaft is to be retimbered from the 400 to the 600-ft. point, where sinking will be resumed.——Heavy shipments are being sent out from the Russell mine in Russell district to the Modern smelter.

Central City, March 26.

GUNNISON COUNTY.

The ore recently opened in the Madonna mine, near Whitepine, has been cross-cut for 60 ft. without reaching the foot-wall.——O. F. Thomas has opened a large body on the Last Chance property near Gothic and has increased the force at the mine. If enough ore of proper grade can be secured it is possible that the Gothic mill and smelter may resume operations.——Work is to be resumed at the Mountain King property as soon as the roads can be opened for freighting.——The Monmouth Leasing Co. has commenced work on its tunnel and is taking in supplies from Crested Butte.

LAKE COUNTY.

The Empire Zinc Co., operating the Colonel Sellers property in California gulch, at Leadville, is producing about 50 tons of ore per day which is shipped to the smelter at Canon City. The new shaft has been completed and self-dumping skips installed.——The Helena mine is to be un-

watered some time this month and work resumed on the lower levels where a good body of ore was exposed before operations were suspended.——Arrangements that were made last year for the installation of new machinery at the Tribune property will probably be completed this spring and work resumed in the mine through the Yak tunnel.——The Colorado-California Dredging Co. has completed prospecting the Hayden ranch south of Leadville, and it is probable that a dredge will be installed this summer.——The face of the Yak tunnel has now reached the upper end of the Maxy claim and is expected to cut the Diamond property within the next few months. A station has been cut on the Resurrection property, but no connection made with the shaft as a large amount of water is still flowing from the diamond-drill holes which tapped the old workings.——The lessees of the Yankee Doodle mine, on Carbonate hill, are shipping 30 tons of ore per day from the 420-ft. level.——At the Carbutt property 30 men are employed and 150 tons of ore is being taken out.

SAN MIGUEL COUNTY.

The Black Bear Mining Co., whose mines are situated in the northern portion of Ingram basin, is preparing for a large output during the coming season. The re-building of the tramway, which was destroyed by fire last year, is well under way and it is hoped to resume operations in the mill about the middle of this month. The ore has improved considerably in the lower levels and a high grade of lead-zinc concentrate will be produced in the mill.

TELLER COUNTY.

A 30-ton lot of screenings recently shipped from the El Paso mine at Cripple Creek by Owen Roberts, assayed 8 oz. gold per ton. The ore was mined on the 250-ft. level where a new shoot has been opened and is expected to average over $30 per ton when mixed with ore from the dumps which are being worked over.——Fogleman & Roach, operating the W. P. H. mine, on Ironclad hill, are shipping ore from the dumps to the Golden Cycle mill at Colorado City. On the lowest level of the property a cross-cut has been started to open the vein exposed in the Forest Queen mine adjoining.——Two cars of smelting ore was shipped from the Lucky Gus No. 2, which is being worked by Harry Moore under lease from the Stratton estate.——The March production of the Jerry Johnson is heavier than for some months past, exceeding 1500 tons, with an average value of $23.——F. N. Dorthy, Leo Cox, and J. W. Miller, have secured a two-year lease on the north end of the Burns claim of the Acacia Gold Mining Co., with royalties graded from 15 to 30% on all ore marketed. The lessees have been prospecting the ground through the Wrockloff shaft, and have found an orebody that assays from $10 to $20 per ton.——The winze from the ninth level of the Ruby mine on Bull hill has been completed and a cross-cut started for the vein. This makes the total depth at the mine 1525 ft. which is the lowest workings in that portion of the district.——An option has been secured by Eastern people on the Rittenhouse properties on Gold hill, and a prospecting permit granted for 60 days. The main shaft on the group is 750 ft. deep, and approximately $50,000 worth of bullion has been taken from the claim.

IDAHO.

ELMORE COUNTY.

The Bagdad-Chase Gold Mining Co., operating the Bagdad-Chase mine, near Atlanta, has shut down and laid off all the men indefinitely. Edgar Van Etten is manager.

OWYHEE COUNTY.

The Black Horse Silver City Mining Co. is running several drifts on a 5-ft. orebody and storing a fair grade of ore on the dump.——The drift on the lowest level of the White Brother's property, in the Flint district, opened a shoot of high-grade ore. There are now 120 sacks on the dump for shipment, and assays of picked samples have run as high as 1800 oz. silver per ton.

MICHIGAN.

HOUGHTON COUNTY.

Operations in the Mohawk Mining Co.'s new shaft, No. 6, sinking of which was begun in 1909 and in the first level of which the Kearsarge lode was found about a month back, are being carried on steadily. The depth of the shaft is now nearly 80 ft. below the place where the first level was cut. Sinking is being carried on at the rate of 70 to 75 ft. per month. At this rate, it will be possible to cut a new level about every five or six weeks. While the rock as being taken from the drift in the first level is not as rich in copper content as that revealed when the lode was first cut, the copper is in workable amount.

KEWEENAW COUNTY.

The Osceola company owns a valuable piece of mineralized territory in Keweenaw county. This land adjoins the one-time Bohemia mine, and exploratory work at the latter exposed a lode of value. Nothing has been done on the property since. The land was originally purchased for its timber, but the mineral rights went with the surface rights when the purchase was made. It is now proposed to investigate it further. The Osceola company is now paying dividends at the rate of $12 per year, and is earning more than that. The production during this fiscal year will run pretty close to 3,000,000 lb., and will undoubtedly be the heaviest in the history of the mine.

ONTONAGON COUNTY.

The good showing in the twentieth level of No. 2 shaft of the Trimountain mine continues. The Trimountain mill is now handling a portion of the Baltic production and will continue doing so till the new boiler-house at the Baltic mill is erected.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—Shallow ore has been found on the Pinkard lease east of Joplin and the shaft is being sunk to 150 ft. The entire tract will be drained when the shaft reaches this depth. So far, the shaft has reached 70 ft., where the ore is first cut. According to drill-holes it extends to 100 ft. No drifts have yet been run.——The Innovator and the McKinley mills southeast of Webb City, idle since more than a year ago, are to resume operations. Each has a capacity of 150 tons. Operations are conducted in hard ground at 185 to 200 ft. The mills in this portion of the field have been idle for some time, but it is reported that a number are planning immediate resumption.——The new 500-ton Culpepper plant north of Carterville on the Cunningham land is almost ready for operation. High-grade blende is being taken from two shafts. It occurs from 155 to 195 ft. The company is installing what is called a 'bull' or extra rougher jig, which will greatly increase the capacity of the plant. This is the first bull-jig installed in this district.——Work at the Carl Junction camp is again becoming active after a rather dull period. Both 250-ton plants of the Mohler Smith Co. are again operating. In the open pit the steam-shovel is at work. The company is installing extra switch tracks. Considerable drilling is also being done.

Joplin, March 26.

MONTANA.

BROADWATER COUNTY.

Reports from the Radersburg district are that the Ohio-Keating Gold Mining Co. is about ready to resume mining and shipping, which has been suspended while the company was awaiting the installation of electric power. The electrical equipment has been received and is being installed. While mining was suspended development work was kept up and the company has a very large tonnage of high-grade ore blocked out and ready for mining. The United Missouri River Power Co. has extended its pole-line to the district and a number of the gold mining companies are using the power.

JEFFERSON COUNTY.

(Special Correspondence).—Two feet of bornite has been opened in the Bertha mine by the Boston & Corbin company in the Corbin district. The discovery was made in a drift on the Bertha vein on the 700-ft. level. The orebody is 9 ft. wide, all of a good grade, and two feet of it are the rich bornite which assays 40% copper and 25 oz. silver per ton.——The Montana-Corbin, the Boston & Alta, the London-Corbin, the Corbin Metal, and the Robert Emmet

Copper companies are all active in that district. The Robert Emmet has just made a connection with the old shaft by a drift on the 200-ft. level, about 181 ft. from the cross-cut driven from the new shaft. The connection makes good ventilation for the mine, and the drift is all the way in ore, the vein being 12 ft. wide, half of it being good ore with a streak 18 in. wide that assays 15% copper, 30% lead, and 120 oz. silver per ton.

Corbin, March 25.

SILVER BOW COUNTY.

(Special Correspondence).—While production in the Butte district is still under restriction all the mines are in exceptionally good condition. B. B. Thayer, president of the Anaconda Copper Mining Co., who has been in Butte several weeks, says the mines of the Amalgamated and allied companies have never been in shape for a bigger production than they are at present, so that if the copper market would justify it the Butte district could produce a record quantity of copper. The production at present continues about 15 to 20% below the normal.——The Parrot mine remains closed, the reason for it appearing in the statement of the Amalgamated company that the ore is of such a low grade that it cannot be mined and treated at a profit on the present copper market. The Little Mina, which produces 125 to 200 tons of ore per day, and also of a rather low grade, is the only property of the company working. However, the merger interests place a remarkably high exchange value on the Parrot in the offer of 90,000 shares of Anaconda for the Parrot property. On a par value basis that gives a value of $2,250,000 for Parrot as against a present par value of $2,298,500.

Butte, March 26.

NEVADA.

CLARK COUNTY.

The Occidental mill in the Eldorado district which started the early part of March has been running successfully, crushing 30 tons of ore per day which plates about $20 per ton.——The Eldorado-Crown 40-ton mill is to start about the middle of this month, and the management is considering doubling the capacity on account of the large number of applications to have custom ore treated.——At the Capital property the management has 20 tons of ore sacked for shipment that will assay from $150 to $200 per ton.——The Nevada-Eagle has stopped sinking temporarily at the 385-ft. level and will cross-cut the vein.——The Independence Mining Co. has broken ground for a new 20-stamp mill and let a contract for its construction. O. A. Ellis is manager.——A carload of 36 tons of ore from the Big Chief mine at Hart, California, has been treated by the Knight custom mill at Searchlight and another shipment is to be forwarded in a few days. The ore yielded $53 per ton on the plates.

ELKO COUNTY.

Snow is rapidly disappearing at Jarbidge and regular work is being carried on at the Bourne, Escalion, Winters, Belmont, Bunker Hill, and other properties.—John Escalion has bonded his claims to the Twin Falls Jarbidge Development Co.——Prenty Bros. have sold the Little Devil, and C. E. Smith the Climax group. The Rambler group brought $9000 and the Fanny $6000.——J. S. Safford describes the Bourne ore as occurring in a rhyolite dike cut by quartz stringers. His samples gave an average of 6.6 oz. silver and 1.06 gold.——Dan Greenwalt is driving on a 4-in. streak of high-grade ore at the Bunker Hill.——Discoveries are reported on Bruneau river, ten miles east of Jarbidge, near the head of East Bruneau and elsewhere.——Many people are coming into the district, though snow still closes the passes to the south, and prices are high. A hotel is being built and with the opening of communications to Elko a rush is expected. The ore in the veins so far opened is not high grade, but contains a fair amount of gold with a little silver. One vein has been traced for about a mile and practically the whole county is staked, though very little work has been done so far on account of the snow.

ESMERALDA COUNTY.

(Special Correspondence).—On the 1000-ft. level of the Clermont workings of the Consolidated an orebody of large size has been exposed and assays have been running as high as 6 oz. gold, with scarcely a trace of copper, the ore now being taken from the drift averaging above $30 per ton.——The dividend to be paid by the Florence company this month, of 10c. per share, will bring the total of such payments to the sum of $735,000. The directors maintain their attitude of refusing to be committed to the payment of dividends at stipulated periods, but from recent announcements it is assumed that the company will be enabled in the future to continue the distribution of profits on the basis of at least 40c. per share annually.——Jumbo Extension has attracted notice of late owing to the opening of a new vein at a depth of 800 ft. in the shaft of the Goldfield Annex lease on the Polverde claim. A shipment of ore of excellent quality was made recently from the LaFoe lease on the Gold Coin claim of the Jumbo Extension, situated near Diamondfield. This is the only production of this company since the Gold Wedge fraction, adjoining the Mohawk, was deeded to the Consolidated company as a result of disputes involving extralateral rights on that claim.——The Codd Mines Co. has secured a three-year extension on its lease on the St. Ives and will sink the 550-ft. shaft to a depth of at least 1000 ft.——The old Daisy lease has been declared forfeited and Millard & Jones, who were working a sublease on this ground, have secured a new lease from the Daisy company and will begin extensive work shortly.

Goldfield, March 25.

LINCOLN COUNTY.

The Reed Mining & Milling Co. is planning to resume work on its property near Delamar. The group adjoins the Magnolia claims from which a large amount of high-grade ore was taken in early days. Several lessees in the same district have ore on the dump waiting the completion of the railroad before shipping.——A test lot of ore from the Consolidated Pioche group was forwarded to Salt Lake to determine the best treatment for the ore. The company is to build a concentrating mill at Pioche to handle the ore, which averages 10% lead, 15 oz. silver, 20% zinc, and $2 gold, before shipping to the smelter.——A. E. Thomas has granted a bond on the Sultan group to Salt Lake parties, and the ore is being hauled eight miles to Goodsprings, from which point it is shipped to the smelter.——The Yellow Pine Mining Co. is now shipping 15 tons of ore per day.

NYE COUNTY.

(Special Correspondence).—The Montana Tonopah has opened a 6-ft. vein on the 615-ft. level, west of the shaft, which appears to be a continuation of the Martha orebody. The ore is a sulphide and the walls are very distinct. The semi-monthly melt of cyanide precipitate yielded 25 bars of bullion averaging 70 lb. each.——The Tonopah of Nevada is building several 400-ton ore-bins in the Red Plume shaft.——The West End company has arranged to obtain more air from the MacNamara, and two more machine-drills will be installed.——The Montgomery Mountain Mining Co.'s properties at Rhyolite will be sold for debt at Salt Lake on April 15, according to a published notice.——The Eclipse 10-stamp mill is now in operation, and the cyanide annex, having a capacity of 50 tons per day, will soon be completed. The company has a lease on the Tramp Consolidated and will devote principal attention to the treatment of ore from this source, though custom ore will be handled as soon as the sampler has been completed. It is proposed to treat $20 ore for $6 per ton, guaranteeing 90% of the assay value.——The Bullfrog Pioneer Leasing & Mining Co. has leased the Mayflower mill and will commence the treatment of low-grade ore at once. The lease will be renewed from month to month, until the Mayflower desires to resume the treatment of its own ores.——The Round Mountain Mining Co. is sinking a new shaft on the Combination claim, 1500 ft. east of the main shaft. It is down 20 ft. and will be sunk 200 ft. before lateral work is commenced.——The Nevada National is arranging for the erection of a milling plant.

Tonopah, March 25.

STOREY COUNTY.

The plans for resumption of work on the Brunswick lode have been completed and work will soon be started through the Sutro tunnel and the Zadig drift. The drift is in hard

rock except for 60 or 70 ft., so but little re-timbering will be needed. At the time operations were suspended the ventilation was poor, while now a strong current of cool air can be drawn from the Sutro tunnel. At the tunnel level a broad belt of quartz assaying from $1 to $14 per ton was crossed.——Frank O. Broili has been appointed superintendent for the Savage Gold & Silver Mining Co. to succeed W. W. Turney, who resigned recently.——The first of the new pumps for the 2100-ft. station of the Ward shaft has arrived at the mine and will be installed as soon as the station is completed.

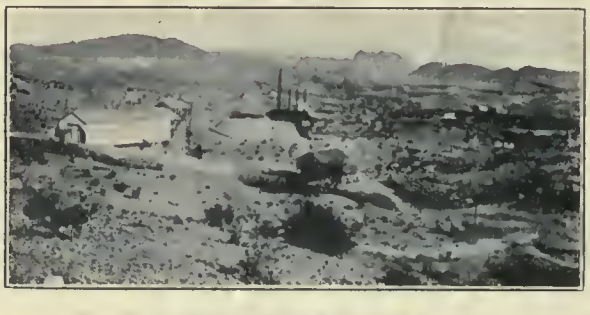
WHITE PINE COUNTY.

The properties of the Pittsburg Ely Copper Co. in the Ely district will be prospected during the summer by a core-drill. A contract has been let for the work and a drill shipped to the property.——John Macart and J. E. Talbott have purchased a group of 14 claims south of the Ely Consolidated property for $14,000.——The steam-shovels at the pit on Copper flat are increasing the output of ore and removing more overburden, as the ground has thawed enough to make shoveling comparatively easy. The output is now from 7500 to 10,000 tons per day.

TEXAS.

BREWSTER COUNTY.

(Special Correspondence).—The 20-ton furnace of the Chisos Mining Co. in the Terlingua quicksilver district is in regular operation. The mine has a monthly output of cinnabar ore which gives a return of about $15,000 worth of quicksilver. The workings are now below the 500-ft.



Terlingua Quicksilver District.

level and the water is said to be giving no trouble. The other mines of the district situated near Terlingua creek are flooded. It is reported that the Griffin prospect in the Shafter district has developed into a bonanza. The ore is said to be very rich and that it is easily mined. The fact that the Shafter mine, which has a record of producing more than $7,000,000 in silver and is still producing at the rate of about $350,000 per year, is situated in the same locality, lends interest to the development of the Griffin claim.

Terlingua, March 25.

EL PASO COUNTY.

A large body of silver ore has just been found in the Beulah mine, situated in the Quitman mountains, six miles from Lasca station on the Southern Pacific. This mine is being worked under lease by John Moffat and is owned by Thomas O'Keefe, of El Paso.

UTAH.

SALT LAKE COUNTY.

Four new steam-shovels and ten standard-gauge engines have been ordered by the Utah Copper Co. This will make a total of 19 steam-shovels operated by the company, and it will be only a short time when all the company's ore will be mined by this method.——The tramway of the Utah Consolidated Mining Co. has been completed and is now ready to handle ore between the mine in Carr Fork canyon and the International plant. While the smelter is not in a position to handle the ore at present, it will be stored in the bins, as the management wishes to have a large stock of ore on hand.

SUMMIT COUNTY.

The drifts on the 400 and 1100-ft. levels of the American Flag mine near Park City have opened shoots of high-grade ore. On the 400-ft. level the vein is 2 ft. wide and on the 1100 about 18 in.——The Silver King Coalition passed the April dividend and is planning to install new machinery, increase the development work, and re-timber the shaft. The Silver King company also owns a half interest in the Conklin and Arthur claims, and at the present time a suit for a division of the interests is pending, so the company wishes to be in a position to buy out the other owners if possible.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—A large body of ore was recently opened on the Iron Chief group, which adjoins the Oversight mine on Cook mountain in the Belcher district. The group consists of seven full claims and has been prospected for several years, but the developments were unimportant, until an open-cut was driven about 100 ft., 30 ft. of the distance being across the apex of the vein which has been traced by open-cutting a distance of about 3000 ft. An open-cut and shaft on the Ironsides claim show that the vein pitches southwesterly into the hill 25 to 30°. The ore contains over 70% iron and small amounts of gold and silver. A vertical depth of 500 ft. may be obtained by an adit on the Keystone claims. The north extension of the Iron Chief vein has been uncovered on the Bonanza and Forrest claims.——The New Republic company has secured an extension of its lease and option to purchase the Republic mine of two years, the royalties agreed to be paid being 10% of the net output the first six months, 15 the second, and 20 the third six months, all to apply on the purchase price, the whole of which must be paid at or before the end of the second year.——The Republic Mines corporation has paid the Pearl Consolidated Mining Co. the second instalment on the purchase price of the Lone Pine, Pearl, and Surprise claims and is getting out large quantities of ore, averaging in value about $45 per ton.——The Ben Hur Leasing Co., which is operating the Ben Hur mine under lease, has cleaned out the old stopes opened by the first company and carried those on the first level to the surface. The leasing company has opened four stopes and is preparing to open another on the first level, from which it has shipped about 4000 tons of ore that varies from $10 to $15 per ton. The value is in gold and silver, with a ratio of one to six. The company expects shortly to install a new boiler and air-compressor to operate ten drills, and later on a new hoist.

Republic, March 26.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—Dominion Copper affairs do not seem to have quieted down even yet. P. F. Roosa, liquidator of the old company, is giving notice that he is about to deal with the affairs of the company under the winding-up act. The chairman of the protective committee of the dissenting stock and bondholders states that counsel has advised that suits for misappropriation of funds and mismanagement against the old officers should be brought in the United States Circuit Court at New York. At the meeting of the New Dominion Copper Co. to be held in June it is likely that there will be a contest for control of the board of directors. The British Columbia Copper Co. at present owns or controls 53% of the stock of the company, but does not control the directorate; Newman Erb and F. L. Sommers, of the British Columbia Copper Co. being only two of the seven on the board. Owing to dissension among the directorate it is difficult to say when shipments from the Rawhide will be started, as some of the directors are satisfied to do development only.——A small crew is at work on the Golden Eagle property, and about 100 tons of ore was shipped last week.——The Greenwood-Phoenix tunnel is now in over 400 ft., and it is thought that the first vein should be cut by the first of April.——At a recent meeting of the directors of the Granby company matters pertaining to dividend were passed over, it being thought advisable to hold this matter in abeyance until the new stock had been issued.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. E. SPURR is at Tonopah.

GELASIO CAETANI is in Colorado.

F. W. BEWLEY is at Boise, Idaho.

H. R. JOHNSON was in San Francisco.

C. W. PURINGTON is expected at New York.

M. K. SHALER will go to central Africa soon.

ROBERT ANDERSON was at Berkeley last week.

H. F. OSBORN was at Los Angeles last week.

T. P. BRINEGAR has left Sonora for Kansas City.

COURTENAY DE KALB was at Los Angeles this week.

S. H. BALL has returned to New York from London.

J. NELSON NEVIUS, of Pasadena, was in San Francisco.

J. P. KEENE is at Pierce, Idaho, in charge of a dredge.

ALFRED JAMES was in New York on his way to Mexico.

J. A. TAFF has returned to San Francisco from Coalinga.

J. H. G. WOLF has returned from Bakersfield, California.

EDGAR COLLINS was at Grass Valley, California, this week.

G. H. ASHLEY has been appointed State Geologist of Tennessee.

HENRY S. WASHINGTON expects to return from Brazil early in May.

SUMNER S. SMITH has returned to San Francisco from Sonora.

ERROL MACBOYLE has returned to San Francisco from Mexico.

J. VOLNEY LEWIS is examining mining properties in western North Carolina.

R. S. MCGOWAN has returned to Hornbrook, California, from San Francisco.

EDWIN E. CHASE, of Denver, has gone to Sonora to examine copper properties.

JAMES F. KEMP has been elected president of the New York Academy of Science.

T. A. RICKARD has been appointed lecturer on mining geology at Harvard University.

HERBERT HAAS has moved his office to 528 Merchants Exchange building, San Francisco.

WALDEMAR LINDGREN will attend the International Geological Congress at Stockholm this summer.

W. F. FERRIER has resigned as geologist to the United States S. R. & M. Co., and SCOTT TURNER has been appointed to the place.

H. S. REED, JR., has resigned as manager of the La Gloria mine and is now at the Tres Hermanos, Batopilas, Chihuahua.

C. A. BEALL has resigned as manager for the Casa Diablo G. M. Co. and will make headquarters hereafter at San Diego, California.

Delegates from the GEOLOGICAL SOCIETY OF AMERICA to the eleventh International Geological Congress to be held at Stockholm, Sweden, in August of this year has been named as follows: Arnold Hague, Charles R. Van Hise, James F. Kemp, Frank D. Adams, and Edmund Otis Hovey.

Obituary.

ALEXANDER AGASSIZ, who died on the steamer *Adriatic*, March 28, was one of the most successful American mining engineers, though known more generally as a zoologist. He was born at Neufchâtel, Switzerland, December 17, 1835, and graduated from Harvard University in 1855. In mining his best known work is that which he accomplished at the Calumet & Hecla in Michigan. A more extended notice of his life will be given later.

MARCH COPPER OUTPUT.

A member of the Copper Producers' Association is quoted by the *Boston News Bureau* as follows:

"The copper output for the month of February, as shown by the Association figures, was 10,000,000 lb. more than was expected. For the current month I predict an output of 110,000,000 lb., notwithstanding the fact that a less production is anticipated owing to the mine curtailment three months ago. The net result will probably be another increase in stock of about 5,000,000 lb. In diagnosing the situation, however, these small monthly increases should not be considered too seriously. Taken as a whole, the first quarter for 1910, when completed, will probably show a decrease in stocks, while the same condition will also undoubtedly prevail for the three months period ending June 30. Exports at the moment are small and the March total shipments abroad will not be large. On the other hand, domestic takings should improve somewhat. As nearly as I can estimate, there have been sold during the past two weeks about 125,000,000 lb., mostly for delivery to American manufacturers. One feature of the recent buying movement was the absence of large buying orders from Europe. Domestic consumers bought sufficient copper to last them through the current month, all through April, and partly through May so that when buying again commences it will call for some May copper together with deliveries for summer. At the moment there is no demand of note for the metal and prices have consequently dropped a peg, and lake may now be had for 13¾c. and electrolytic for 13½ to 13⅝."

The Anaconda Merger.

The companies absorbed by the new Anaconda company will receive its shares as listed below:

Companies absorbed.	Shares.
Boston & Montana	1,200,000
Butte & Boston	300,000

COMPANY REPORTS.

DALY-JUDGE.

The Daly-Judge Mining Co., of Park City, Utah, had a prosperous year in 1909, the cash balance at the end amounting to $222,038. The ore statement shows 3437 dry tons of ore sold crude and 47,872 concentrated. The concentrate brought $222,609, the zinc middling, $100,918, iron middling, $27,467, and the crude $77,725. Miscellaneous receipts brought the total up to $437,631. The expenses for the year were $347,590. Costs are given as follows:

	Tons.	Rate.	Amount.
Mining	51,309	$3.03	$155,649
Concentrating	47,872	0.95	45,596
Marketing	33,364	0.76	25,496
General Expense..	51,309	0.25	12,635
Exploration	51,309	1.75	89,756
Total		$6.41	$329,132

Construction work cost $15,117, a new air-compressor having been installed. Development amounted to 5165 ft. Total sales since the incorporation of the company have amounted to $2,486,155. Mining extends to the 1500-ft. level. The company is interested in the Snake Creek Mining & Tunnel Co., which proposes to underdrain the district.

MONTGOMERY SHOSHONE CON. M. CO.

This is a holding company which controls the Montgomery Shoshone Mines Co., Shoshone Polaris Mining Co., and Bullfrog Reduction & Water Co., concerned with mining and reduction of gold-silver ore at Bullfrog, Nevada. The principal mine is the Montgomery Shoshone, which is worked in part through a 'glory-hole', but has also been opened by shaft and levels to a depth of 700 ft. John G. Kirchen, the general manager, finds it impossible to make an accurate estimate of ore reserves owing to the irregular character of the orebody. In the stopes 9500 tons of broken ore are reported, valued at $6.50 per ton. Within the year ended December 31, 68,632 tons of an average value of $7.57 were mined and treated with an extraction of 87%. The cost of the milling is given at $2.27 per ton. The cost of mining may be figured by dividing the combined operating expenses of the two mines, $140,756, by the total tonnage, at $2.05. It is impossible with the data given to make proper allowances for development and ore reserves, but it is evident that, considering desert conditions and the irregularities of the deposit, the cost is low. That development was not neglected is indicated by the fact that 6982 ft. of drifts, cross-cuts, raises, and winzes is to be credited to the year's work. Important improvements have been made to the mill, which has been described in the MINING AND SCIENTIFIC PRESS, February 19, 1910.

UNITED STATES STEEL.

The eighth annual report of the United States Steel Corporation shows a substantial recovery from the depression of 1908, the figures following rather 1907 than the last preceding year. The gross sales and earnings increased $164,074,411 or 34%, and the net earnings $39,643,703 or 43%. The gross receipts were $646,382,251 and the net earnings $131,491,414. The total number of employees is given at 195,500 and the annual payroll $151,663,394. The total production of finished products for 1909 was equal to 75% of the normal maximum capacity of the properties. That the increased profits were related to lower prices quoted is indicated by the fact that the average domestic prices received in 1909 on finished products were 14.3% less than in 1908. On foreign sales the decrease amounted to 7.8%. Export shipments, however, increased 26.3% in the year and there were large unfilled orders on the books at the close. The bonded indebtedness of the corporation and its subsidiaries was increased $12,718,639 and totaled, December 31, $607,584,173. Since the formation of the corporation $495,212,235 has been taken out of earnings and put into the property in the form of improvements, enlargements, or extensions; an amount not much below the total of the common stock, $508,302,500.

PUBLICATIONS RECEIVED.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

HYDRAULIC MINING, with Supplements on Roads and Motor Traction for Mining. By C. C. Longridge. 8vo. Pp. 352, appendix, index, ill. *The Mining Journal*, London, 1910. Price $7.

A sharp demand has long existed for a work on hydraulic mining, giving modern practice in testing and in operating, with full details. The classic work of Augustus J. Bowie has not become obsolete, but neither does it completely answer the needs of the present-day miner, and it was always wanting in explanation of the minor matters of operation. Specific detail of that kind is needed as much as elucidation of general principles. Mr. Longridge has gone far toward supplying the need. The volume before us brings together an immense amount of information. The author does not appear to draw from a large practical experience, though he has evidently had sufficient contact with field-work to give him a proper sense of the relative importance of the various features of the work. His reading has been wide and up to date. The discussion of the relations of geology and physiography to placer deposits is illuminating. He gives the MINING AND SCIENTIFIC PRESS credit for calling attention to the influence of 'creep en masse' of the gravel-fill in valleys in causing concentration of gold on bedrock. The conditions favoring gold accumulation are explained in a manner that will be helpful to prospectors. His classification of placers is interesting, but is open to some criticism as an attempt at discriminations which are too minute. The description of methods of testing is in accord with recent practice, but in this instance more detail would have been helpful. We commend the extended treatment of the engineering features, such as ditch and flume-construction, pipe-lines, and the like, accompanied with mathematical tables and examples of the calculations necessary. The chapter on dams is perfunctory, but this subject is necessarily one that cannot be condensed. Recourse must be had to extended treatises on dam-construction. All the appliances used in hydraulic mining are described, with ample illustrations, many of which are working drawings. The chapter on hydraulic elevators, giants, and nozzles, and the details of the duty of water in the various operations of hydraulic mining, is the best source of such information that we know. In the chapter on traction engines the Renard system is briefly explained. This offers some peculiar advantages, doing away with the heavily loaded draft-engine. The book is not well arranged, and is unattractive in appearance, but it is undoubtedly the most exhaustive treatise on hydraulic mining at present available.

THE MINING MANUAL FOR 1910. By Walter R. Skinner. Published by the author. London, 1910. Price $5.50.

Comment upon a standard reference book such as Skinner's Mining Manual is almost unnecessary. It has become an essential part of every office equipment where there is interest in the mines owned by British companies all around the world. It contains information upon 3600 mining properties, with the details needful to one interested in the financial status of these enterprises. It also contains, among much statistical matter and information of general interest to the mining public, the names and addresses of 1400 mining engineers and mine managers, and a dictionary of mining terms. The latter needs a thorough revision, since there are many inadequate and misleading definitions, such, for example as that of 'leaching', which is said to be "the process of separating metal from salts by treatment with a solvent."

RESULTS OF SPIRIT LEVELING IN ILLINOIS, 1896 TO 1908, INCLUSIVE. By S. S. Gannett and D. H. Baldwin. U. S. Geol. Surv., Bull. 421. Pp. 74. Washington, 1910.

REPORT OF THE DIRECTOR OF THE MINT, FOR THE FISCAL YEAR ENDED JUNE 30, 1909. Pp. 310, index. Washington, 1909.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

D. W. T., Butte, Montana: No. 1, diabase; No. 2, diorite.

R. L. L., Aire Libre, Mexico: The rock samples are phonolite.

R. J. H., Aqua Salada, Mexico: A mixture of epidote and garnet.

S. I. C., Dunsmuir, California: Massive serpentine sprinkled with pyrite.

C. C. W., Pahreah, Utah: The green mineral is torbernite and the yellow probably autunite.

E. S. R., New York: The specimen is an impure lime carbonate or travertine, and contains clay but very little magnesia.

M. J. O., Denio, Oregon: The specimen contains chalcopyrite, tetrahedrite, pyrite partly oxidized black, quartz, and barite.

A. H. B., Fullerton, California: No. 1, augite-andesite; No. 2, quartzite; No. 3, banded or schistose quartzite; No. 4, mica-schist.

CATALOGUES RECEIVED.

Braun-Knecht-Heimann Co., San Francisco, and The Braun Corporation, Los Angeles. An especially complete and attractive catalogue of assayers' and chemical laboratory apparatus and supplies. Illustrated. 6½ by 10 inches. 528 pages.

The Williams Patent Crusher & Pulverizer Co., Chicago. 'Coal Crusher Bulletin'. Illustrated. 7 by 9½ inches. 8 pages. 'Anthracite Mine Debris Bulletin'. Illustrated. 7 by 9½ inches. 8 pages. 'Facts Worth Reading'. Illustrated. 4 by 6 inches. 36 pages. 'Users of Williams Mills'. Illustrated. 4½ by 9 inches. 8 pages.

COMMERCIAL PARAGRAPHS.

Montgomery & Case have opened an office at Battle Mountain, Nevada, to do assaying and engineering.

The Trojan Powder Co. announces the removal of its California office from Oakland to the Phelan Bdg., San Francisco.

T. H. Proske, of Denver, recently shipped two 30-ft. D 24 Ajax drill sharpeners to Brazil for use on railroad construction work.

The Trent Engineering Co. has moved its Los Angeles office to the Union Trust building, at the corner of Fourth and Spring streets.

The Southwestern Machinery & Supply Co., Los Angeles, agents for the Fuller Lehigh mill, has moved its office to 504 Central Building.

The Kelly Filter Press Co., which has taken quarters in the new Felt building, at Salt Lake, reports the shipment of a second 50-ton press to the Treadwell mills at Treadwell, Alaska.

The Hammond Iron Works, Warren, Pa., advises that it is furnishing twelve Pachuca tanks, 15 by 47 ft., and numerous plain tanks and zinc boxes for the new plant of the Palmilla Milling Co., at Parral, Mexico.

The Inter-Ocean Steel Co., Chicago, announces that its plant at Chicago Heights will soon be ready to produce locomotive and car wheel tires, roll shells, die rings, and steel flanges. Julian Kennedy is chief engineer.

The S. M. Hildreth Co., New York, is putting a collapsible steel 'horse' or trestle on the market. It is built up of structural shapes and is said to be unusually rigid when extended. When folded the horse takes up very little room and is particularly convenient for transportation and handling.

The Atlantic Equipment Co., New York, announces that it has contracted with the Oliver Iron Mining Co., to furnish all steam-shovels used by the latter concern during the coming season. The class 80-18-3 shovel was selected after a severe test in the Mountain Iron and the Bart-Pool mines during 1908-1909.

On March 1 Alexander Backus disposed of his holdings in the Vulcan Steam Shovel Co., Toledo, Ohio, and retired from the presidency after an active service of twenty years. The new owners and officers of the company are H. P. Eells, president, and G. F. Steedman, vice-president. Carl Horix, who has been acting as general manager for some time past, will continue in this capacity.

A. J. McCone, of Reno, Nevada, is preparing to manufacture a double-drum friction, worm-gear hoist for sinking prospecting shafts from 100 to 300 ft. One drum is for the load and the other for a counter-balance. It can be operated by a 3 to 5-hp. gasoline engine or electric motor. The outfit includes a self-dumping bucket and a car-loading chute. He has an outfit set up for demonstration.

On May 1 the Dearborn Drug & Chemical Works will move its general offices and chemical laboratories at Chicago from the Postal Telegraph Bdg., to the new McCormick Bdg., on Michigan avenue and Van Buren street. The Dearborn company will have the entire frontage on Michigan avenue for its offices and laboratories, with a total floor space of more than 5000 square feet. The Dearborn company extends a cordial invitation to old and new friends to visit its new headquarters.

Abbot A. Hanks announces his removal to 630 Sacramento street, San Francisco. This well known assaying office was established in 1866 by Mr. Hanks' father. With the exception of the year following the catastrophe of 1906 the firm has been situated within a few blocks of its present location. The business has grown from a small assaying office to complete chemical and metallurgical laboratory. The new firm makes a specialty of representing shippers at the San Francisco smelters. The new building was designed especially for the use of Mr. Hanks, and provides all modern equipment.

EDITORIAL.

AN ENGINEER in the Cabinet is suggested by *Engineering-Contracting*. Why not? Many engineers know enough law to qualify even under the present administration.

THE American Electrochemical Society will hold its spring meeting at Pittsburg, Pennsylvania, May 4, 5, 6, and 7. A full program and interesting excursions are promised.

JAPANESE are ubiquitous and useful. It is announced that 'Japanese spies' have been arrested at Manila. The importance of the matter dwindles when it is recalled that this story annually appears just about the time Congress is asked to vote two more battleships.

CANADA produced 54,061,106 pounds of copper in 1909, according to the statistics collected by the Dominion Government. This represents an increase of two per cent over the output for 1908. The bulk of this copper came from British Columbia, though Ontario yielded over 15,000,000 pounds.

MINERS' INSTITUTES were provided for by the special session of the General Assembly of Illinois just adjourned. Unfortunately the Attorney General finds the law to be unconstitutional since the matter lay outside the subjects mentioned in calling the Assembly together. The Governor has, accordingly, felt obliged to veto the law so that this important measure will need to be re-enacted at the regular session next winter.

INSURANCE against loss through failure to realize on advance royalties is provided in the case of the United States Steel Corporation by deducting from the surplus an amount to be held against such a loss. In 1906, $2,500,000 was so set aside. To this $300,000 was added in 1908, and $3,200,000 in 1909. In all, therefore, $6,000,000 is now held. It is known that in certain cases where the Corporation holds iron-ore land subject to a minimum yearly royalty, less than the minimum of ore has been extracted. This is, of course, equivalent to advance payment for mining, and money so spent properly constitutes an asset. Since, however, orebodies are subject to vagaries and even the best prospecting only allows of estimates of tonnage, it is always possible that less ore will be realized than the minimum estimated and so paid for. In the case of the Mesabi orebodies this is not a very probable contingency except possibly where there is a definite time limit on the lease. The fact that provision is made for such possible loss indicates how carefully the Corporation's affairs are managed.

PUBLIC confidence in the copper market has been shaken as a result of the unimproved demand for the metal. This has been reflected in the general decline of copper shares, in which subsidence practically every important producer in America has been affected. Even the stock of the Calumet & Hecla fell from 685 to 597, Utah Copper has shrunk to 43¾, Nevada Consolidated to 20⅞, while Amalgamated went from 90¾ to 74. The greatest shrinkage was that of Granby Consolidated, which had stood at 111¾, and was shortly quoted as low as 37. The special reasons for this are explained in our New York letter. These are only examples of a universal decline in value, which of course was exaggerated by the timidity of the speculating public. Such a depression is wholly unwarranted, and no one would pretend that the condition of the metal market and the outlook for the future were such as to mean a depreciation in the actual value of the stocks of $156,000,000, as the stock market quotations would indicate. The lack of discrimination by the public between the producers of low and high-priced copper is evidence of this.

Goldfield and Grass Valley Mines

Production by the Goldfield Consolidated Mines Company continues at the same extraordinary level as for many months past. During March the recovery amounted to $950,000, being at the rate of 93.5 per cent from ore averaging $38.20 per ton. We have taken occasion heretofore to remark upon this phenomenal result, illustrating the skill in technical operation and general management of those who have been in charge. The total operating cost, including administrative expenses, was $8.26, and the loss in tailing amounted to $2.51 per ton. There are few cases of equal extraction from high-grade ores. Mr. J. R. Finlay, the manager, reports additions to the ore reserves during the month of March of 60,000 tons, being almost double the tonnage milled. This is a most gratifying feature of the situation, which is increased by the fact that no diminution of the assay value of the ore has taken place. The great gold mine of Nevada will evidently long hold its own as the richest in the world. It is interesting to compare with this the results at the North Star mine, which is the greatest gold mine in California. The annual report just issued shows a total output for 1909 of 91,610 tons, averaging $13.59 per ton, which was treated at a total cost, including development, of $6.42. This has been achieved at a mine working to a depth of over 5000 feet on the incline, with a narrow vein, which necessarily adds to the cost of operating. The reserves now blocked are sufficient to supply the mill for several years. The success attained reflected credit upon Mr. A. D. Foote, the distinguished engineer in charge. While the North Star has had no such dazzling career as the Goldfield Consolidated, its long and steady production and its successful operation since 1884, have given it a standing that commands universal admiration. In this period of twenty-five years it has yielded a gross amount of $10,745,046, out of which dividends of $2,486,989 have been paid.

Alexander Agassiz

In the death of Alexander Agassiz the world has lost one of its greatest mining engineers. It is not usual to think of him as a mining engineer, for his distinction in the public eye was due more to his achievements in pure science. After all, it is the contributions to knowledge rather than the economic results which a man attains that win applause and lasting honor in the world. This is one of the things that keeps alive our faith in humanity as something more than a mechanism to produce iron and steel and copper or to raise wheat and to irrigate alfalfa. It is a tribute of the highest sort that the scientific and uneconomic achievements of Alexander Agassiz eclipsed his superb success in establishing and guiding the greatest single mining enterprise in the world. It was due to him that the Calumet & Hecla copper mine in Michigan was placed upon a paying basis; it was his genius that realized the hopelessness of attempting to found a copper industry on the Michigan peninsula based upon enriched spots in the great conglomerate and amygdaloid lodes, but foresaw the possibility of building it up by economical methods of operation on a large scale, utilizing the average low-grade ore. The Calumet & Hecla has distributed to its stockholders $110,550,000 in dividends, making the largest disbursement reached by any mining company in the world, and this from a copper ore that has yielded first and last about two per cent of metal. This splendid success made Mr. Agassiz a multi-millionaire, in the clean and noble way of winning fortune from the earth, adding at the same time to the world's wealth. There was never any manipulation of stock nor bleeding of the public. He could show his books and papers to the world and there would be none to reproach him. This wealth, moreover, did not come as sudden riches in answer to a rubbing of Aladdin's lamp. Mr. Agassiz was born poor; the only son of the intellectual giant Louis Agassiz, who had "no time to make money," being so busy in blazing new paths of knowledge through the unknown. He started in life with no inheritance save a sound training in the best scholarship of the age. He graduated from Harvard in 1855 in his twentieth year; in 1859 he began active duty in the West as a surveyor on the Coast Survey in California. It was in 1865 that he threw himself into the task of developing the Calumet & Hecla. The peninsula was a wild place in those days; inaccessible, and dreary; its vast stretches of swamp had not been reclaimed. There he lived and worked as a pioneer for four years, struggling to win where everyone predicted failure, inspiring a handful of friends with confidence while the world laughed at him as a scientific dreamer. But the dream came true, and his supporters were well rewarded.

His distinction as a zoologist and geologist has placed him upon a higher plane than his economic efforts, and in the magnitude of his scientific labors he perhaps excelled those of his father. The difference is that the world is now accustomed to the tenets of progressive evolutionists, so that his contributions carry with them no hint of the iconoclast, and hence are less spectacular. The fruits of his

work on the famous Albatross expeditions, however, built higher the structure of zoologic science. His most notable geologic work consisted in the disproval of the fascinating theory of coral island formation, which Darwin and Dana had worked out like a scientific romance. The world thus lost a pretty conception, but Alexander Agassiz brought us back to truth. No great South Pacific continent had existed and subsided below the waves. With the homely application of the diamond-drill he showed that the accumulations of coral were not due to gradual submergence. His labors for the advancement of knowledge, were conducted at enormous outlay from his private fortune. He will be remembered as a rare man, great as a scholar, scientist, and engineer.

What a Mining Bureau May Do

Our esteemed contemporary in New York, *The Engineering and Mining Journal*, is violently exercised over the probability of the establishment of a Federal Bureau of Mines. The functions of such a Bureau, and possibly its utility, are matters concerning which men differ, but surely reasoning is better than ridicule as a means of honest opposition. Failure to adduce argument suggests prejudice rather than knowledge. On another page of this issue Mr. S. B. Christy, whose long and eminent service at the College of Mining of the University of California gives weight to his words, discusses the arguments pro and con. For ourselves, we cannot believe that the distinguished metallurgist who edits our Eastern contemporary fails to see the need of further improvement in mining and metallurgy; nor can we believe that he is so pessimistic as to doubt the possibility of such improvement, or so ignorant as not to know that it must be based on research. It is surely a fair assumption that well directed research in chemistry, physics, and related sciences, will supply many of the missing data, and equally certain that a corps of qualified engineers and scientists with means and time to study these problems in the broadest way, may be expected to be helpful rather than harmful to the industry. That we have come so far on the road by present methods is no argument against taking advantage of conceivable additional aid. To insist that improvement is possible is not to deny that there already has been progress, any more than to propose additional means of research is to promise immediate solution of difficulties. Surely there can be no real misunderstanding on this point. As to the suggestion that a '$6000 per year director' would either prove ineffective or be gobbled by the Guggenheims, it might be well to remember that many men are already adding yearly to the store of mining and metallurgical knowledge in the colleges at less than this, and even editors of technical journals are known to be useful for years at such a salary without being abducted by any smelting company. Why should not the men in the Bureau of Mines serve a useful purpose, and even make important discoveries at the same stipend? If such an expert, after making and publishing such discovery, be offered a large salary by a corporation that desires his aid in making practical application of the new principle, we shall be first to congratulate both the man and the corporation, the one on having had the opportunity, temporarily free from the pressure for immediate commercial results, to ground himself in principles and to perfect his researches, and the other on securing a capable and efficient man. It has momentarily inconvenienced the Geological Survey, but the country at large has not suffered because Messrs. W. H. Weed, J. E. Spurr, J. M. Boutwell, C. K. Leith, J. D. Irving, and C. W. Purington, to mention only a few of the brilliant men who were trained in the Government service, are now engaged in private work. Does any one seriously believe that the Geological Survey has hampered rather than helped the mining engineering profession? The fear that a Bureau of Mines will impede the work of private engineers seems particularly ill founded. The Canadian Department of Mines has not done so. Indeed, it gave to the gentleman who has urged all these objections an excellent opportunity to study and report upon zinc mining and metallurgy north of the boundary; an opportunity which he and his associates improved in a most distinguished manner. Cheer up! While we do not for one moment accept the statement that "the chief purpose of a Bureau of Mines is to provide agreeable jobs for some amiable gentlemen," the bill as recommended to the Senate does provide that "there shall be in said Bureau such experts and other employees, that may from time to time be authorized by Congress." We see no reason why under this provision eminent engineers should not occasionally be employed to investigate special problems here as in Canada; and the Secretary of the Interior is authorized to fix the compensation at whatever may be necessary, with the single exception that it must be within the appropriations.

Establishment of a Federal Bureau of Mines is a simple measure of justice to miners and mining. It is paternalistic, but so is our Government, and has always been. The surest help is that which stimulates self-help and nothing does this like dissemination of accurate knowledge. This has been shown in the help given the farmers by the Department of Agriculture aiding development without interfering with any proper private activity. That Department began as a Bureau and developed on its merits. The Department of Commerce and Labor touches, directly, fewer persons and is concerned mainly with larger consolidations of interests. Its work also began under Bureau organization, but the Department even in its short life, has accomplished much good. The time may come when a Department of Mines will be in order; that is a matter for the future to determine. The time is now here, however, when a Bureau of Mines is needed, and neither trickery in the Senate nor ridicule on the part of those who misinterpret public opinion ought to be allowed to defeat it. The West is certainly for a Bureau of Mines, and this is true of the sentiment not only of the men in the ranks, but of those who manage large and successful mining and metallurgical enterprises. As to the wishes of those living in the shadow of Wall Street "between New Jersey and the Ocean" we cannot profess to have accurate information.

Geology Applied to Mining

By T. A. Rickard.

(Continued From Page 481.)

*Accepted ideas concerning the origin of ore deposits may be illustrated by describing briefly the manner in which a simple type of lode is supposed to have been formed. Let us take a gold-bearing quartz vein in granite: The vein occupies a fissure formed by a dislocation connected with the intrusion of igneous rock, which appears in the vicinity in the shape of dikes. The quartz contains iron sulphide, as pyrite, which near the surface is oxidized to hematite or appears in hydrous form as limonite, staining the white quartz red. The gold is found native and in coarse particles at the outcrop and for a variable depth, but below the zone of oxidation the gold is rarely visible and is associated intimately with the pyrite. Oxidation ceases a little below the level at which water freely enters the mine-opening. At a thousand feet the ground becomes dry and concurrently the vein becomes less rich in gold. At a depth of three thousand feet the quartz carries only traces of gold, but the gold-contents of the vein have not diminished steadily in depth; on the contrary, extreme variation has been noted both laterally and along the strike of the vein and vertically at different levels. In depth the rock enclosing the vein becomes harder, less fractured, and less moist. The pyrite tends to diminish in quantity. Even the vein-fissure is narrower, as if the rock were squeezing it on either side. The temperature increases in depth at the rate of 1°F. for every 50 ft.; obviously this increment indicates a depth at which the rock will be plastic or subject to deformation, incompatible with the existence of fissures or similar channels for water-circulation.

Given these facts, let us try to reconstruct the life-history of this gold vein, which is the fossilized remainder of a conduit through which mineralized solutions passed, not once only but at successive epochs, and for a period so long that as compared to it the time of one of the generations of man is as the life of a spring flower to the course of a star. As Emerson said: "Respect the *naturlangsamkeit* which hardens the ruby in a million years, and works in duration in which Alps and Andes come and go as rainbows." Indeed, the formation of a gold vein is an example of the cumulative effect of the infinitely little. We assume that the minerals—the quartz, the pyrite, and the gold—were precipitated from solution, but the solution, as compared to that of a chemist in his laboratory, was as weak in its dilution as it was potent in its volume. You will recall that Judd speaking of the hot spring at Bath points out that this, although an unimportant geological agent, brings daily to the surface 180,000 gallons of water at a constant temperature of 120°F., and as the spring is known to have been doing its duty at the time of the Roman invasion of Britain, it is estimated to have brought to surface in solution enough material to form a large volcanic cone. But the feeble spring that wells quietly to the surface at Bath is the product of thermal activities almost dead, while the gold vein is the sealed conduit of solutions that pulsated with the very life of the volcanic energy issuing from within the warm heart of the earth.

The vein is in granite, which is also traversed by dikes of andesite. This andesite elsewhere in the district penetrates some of the formations overlying the granite, but the andesite is itself overlaid by other more recent sedimentary strata; thus the age of the dikes is ascertained to be, let us say, early Tertiary. At that time this portion of the earth's crust was subjected to strains, due to the adjustment of a cold exterior upon a cooling and shrinking interior. The adjustment may have taken the form of a slow movement, which folded the yielding sedimentary rocks and cracked the less pliable granite. The granite was fissured down to the molten magma or to a horizon where the substance of this earth is subject to such a heat as to remain solid only because excessive pressure prevents liquefaction. As soon as the pressure is diminished, in place and temporarily, by the shifting of the crust and the formation of fissures, the magma becomes molten and rises in the cracks toward the surface. No gaping crevasse is assumed; the magma or lava follows and occupies the fissure as it is formed. The action may be compared to that of water filling the cracks in a sheet of ice; and as the water rising through a crack in the ice is referred to the body of water beneath that ice, so we connect the lava in a dike with the magmatic mass under the cold crust of the earth. Thus the dikes were formed.

The period of vulcanism was followed by a quiescent stage during which molten lava ceased to issue and was succeeded by watery emanations steadily more tenuous until they became essentially only hot water containing silica in solution with traces of iron and gold. This gradation expresses the process at work in the depths, whereby the molten mass undergoes differentiation by segregation of its constituent elements, the heaviest being first to crystallize, followed by others less basic, until finally all of the magma has consolidated, leaving a residuum of heated silicious water.

Meanwhile the granite was still subject to strain and to rupture; the dikes and other bodies of intrusive rock were cooling, and as they cooled they permitted cracks to be formed, sometimes along the lines of weakness they themselves now afforded. Up these cracks came the final products of magmatic segregation—the hot silicious waters containing the substances from which the gold vein was to be built.

Then supervened a long period of thermal activity, the heated solutions circulating through cracks and fissures after the manner in which hot water is impelled through the pipes in a house. Expansion under heat becomes an enormous force through the generation of steam, for one cubic inch of water makes one cubic foot of steam. Indeed steam is a prime factor in the formation of both dikes and veins. Andesite ordinarily fuses at 2520°F., but it is liquefied at 800° in the presence of superheated steam.

*The Le Neve Foster Memorial Lecture, delivered at the Royal School of Mines, London, on March 4, 1910.

the presence of which is indicated by the vesicular structure of lava, as well as by the emission of enormous volumes of water-gas, which constitutes the clouds of so-called 'smoke' characteristic of volcanic outbursts.

The question now arises as to the source of the hot waters that formed the gold-quartz vein. As previously stated, until recently it was held that all such solutions formed an integral part of the circulatory system originating at the surface from rainfall; that is, the underground waters were supposed to be of meteoric origin. But the weight of evidence is against such a theory: We know that in depth the rocks become less open to the passage of water, the gravitative stress that enables it to sink at the surface is overcome by increase of temperature and by a pressure that tends to close every opening. At a depth measured by about 30,000 feet the pressure and temperature have so increased as to produce deformation of the rock; hence no openings save of microscopic size are possible. Moreover, at about the same horizon the 'critical point' of water would be reached. At a temperature higher than 773°F. water cannot exist in liquid form, no matter how great the pressure; it becomes dissociated into its constituent gases. Allowing for an increment of 1° for every 50 ft. of descent this temperature would be reached at 34,700 ft. Thus there is a vertical limit to the descent of surface water.

Whence then comes the enormous volume of water ejected by volcanoes and thermal springs? At one time it was supposed that the sea found a way into cracks leading to volcanic vents and in a few instances this is believed to have happened to a minor degree, but this simple theory does not explain the emission of equally large volumes of steam in regions distant from any large body of superficial water. Briefly, it is held now that the volcanoes make the sea, rather than the contrary, that is, that the large bodies of water now covering the earth are the product of segregation from the cooling magma out of which the planet has been evolved. Thus we look to the depths—not to the surface—for the origin of the thermal waters that formed the gold vein. Regional disturbances had folded and fractured the granite, so as to create breaks reaching into the magma from which the andesite arose; and when a renewal of unrest, due to later re-adjustment, opened fresh fractures extending below the stony exterior of the earth, then the magmatic waters, the end product of segregation, rose under propulsion of steam until they reached the zone traversed by meteoric water, and forced their way through fissures and fractures even to the surface, where in places they issued forth as geysers or 'gushers'.

The dilute siliceous solutions that thus finally reached the surface had traveled patiently along the underground waterways, dissolving and precipitating, enriching and impoverishing themselves, under the compulsion of chemical and physical conditions. Hot water under pressure, and especially as superheated steam, is a powerful solvent. At a depth below 10,000 feet and a temperature higher than 212° F., the dark silicates would be readily corroded and would yield both their silica and their metallic ingredients. The ability to carry matter in solution is increased by heat and pressure until saturation is attained, but at excessive temperatures the rapidity of solution is gained at the expense of stability. Thus at the greatest depth the interplay of solutions is rapid and the result unstable. Selective solution has full play. But as the waters ascend the pressure decreases and they become incapable of carrying so much material in solution. Then precipitation follows. Speaking generally, we may say that in the approach to surface the lessening of temperature and the decrease of pressure favor precipitation, as in depth, with augmenting heat and pressure, the reverse action, namely solution, is predominant.

Ore deposition may be regarded as a process of natural concentration: the vein is the depository of substances brought thither from many directions and solidified from solutions of extreme tenuity. As silica forms 60% of the substance of the earth's outer covering, it is not remarkable that it should be found in concentrated form as quartz in veins. But as the end product of magmatic segregation the siliceous solutions followed naturally in the wake of eruptive activity and on the wane of vulcanism.

For the iron we may look to the dark silicates, which predominate in basic igneous rocks. The emission of sulphur compounds at volcanic vents points to the existence of that element as an original constituent of deeper rocks; thus the source of the iron sulphide, or pyrite, is indicated. Such sulphide of iron may be carried in alkaline solutions, in carbonated waters, or dissolved even in pure water. Carbon dioxide in liquid form is found plentifully in the microscopic cavities of rocks, and carbonate minerals are widely distributed. During periods of unrest, when the rocks are fractured, this carbon dioxide is liberated and when siliceous waters penetrate limestone or dolomite the process of silicification is accompanied by the formation of carbonic acid. Thus a solvent is let loose. It is probable that water rich in bi-carbonates, and with an excess of carbon dioxide, was the chief solvent for the iron compounds from which the pyrite originated.

Next, the gold. Gold is widely disseminated in nature: in sea-water, in sedimentary rocks, in igneous rocks, it has been detected, but not until it has been concentrated to a point rendering it worth while to go to the pains of extracting it from its place amid less valuable minerals does the gold become of economic importance. The precious metal in a vein has undergone great and varied vicissitudes; it may have been laid down from magmatic waters that retained it at the end of a long process of segregation: it may have been leached from the iron and manganese silicates; it may have been derived from deeply buried oceanic sediments; it may have passed through each and all of these stages of existence, but in any case it is likely to have been dissolved, precipitated, redissolved, and re-precipitated, several times, before resting finally at the spot where it is struck by the pick of the miner.

Of solvents for gold there are many: Chlorine is prevalent in nature and used in metallurgy. Hydrochloric acid is one of the products of volcanic vents.

Iodine, which is a constituent of seaweed and exists in oceanic sediments, may have played a part. Alkaline sulphides may be mentioned. Iron persulphate is a more likely solvent, in view of the association with pyrite.

When ascending thermal waters containing gold in solution approach the earth's exterior they become susceptible to precipitation; if highly saturated the decrease of temperature and pressure is enough to compel unloading of the precious freight, but even for dilute solutions there lie in wait many reducing agents. Organic matter, in the form of carbonaceous remnants of vegetable organisms imbedded in the sedimentary rocks, is one of these. Even pyrite itself is a likely agent in the precipitation of gold. Ferric sulphate is a solvent, but ferrous sulphate is a precipitant. Once the gold is brought to the shallow horizon and is subject to the diverse chemical and physical conditions obtaining within the water-zone it is the sport of continual change, one effect of which is to produce the concentrations constituting rich ore.

The gold vein is a victim to nature's mutability. No sooner is it made, than it is attacked by forces of decomposition and decay. Life and death in nature go hand in hand; integration and distintegration pursue each other eternally. The uppermost portion of our quartz vein is exposed at surface to erosion and weathering. The minute crevices of the white quartz are penetrated by the rain, which, on freezing, serves as a wedge more powerful than steel to shatter the rock. The maximum density of water being at 39°F., there is an expansion between this temperature and the freezing point, sufficient to constitute a powerful agent of disruption. Moreover, the moisture acting upon the pyrite in the presence of air oxidizes the sulphide and forms ferric sulphate, which is set free to attack the gold. Thus the constituents of the vein near the surface are released for transport in the water-circulation, and merge into the meteoric waters, which, by gravitative stress, pass downward. The weathered cap of the vein remains as a honeycombed vertically tabular body of quartz, impoverished in gold, stained with iron oxide, and loosened by frost. The gold is carried a little deeper, but probably not far, for reducing agents are plentiful and speedy re-precipitation is likely. Thus an enrichment is produced, the gold from the upper part of the vein being superadded to the normal gold content as originally laid down. If, now, further erosion lowers the surface and removes the impoverished cap, the result will be to bring the enriched portion of the vein to the daylight or to the grass-roots, where the adventurous prospector haply may find it, greatly to his joy and possibly to his undoing.

My attempt briefly to indicate the processes by which a gold vein is formed would be misleading if I failed to emphasize the important part played by structural conditions. Deposition of ore is affected by the physical, and also chemical, conditions created by variations of rock-texture, by changes in the width and dip of the vein-fissures, by faults, by crossings with other veins, and by a multiplicity of local modifications such as the miner has a keen eye to appreciate. The scientific man helps to explain them and thereby sharpens the eye of the unscientific to observe them. By furnishing a clue to the vagaries of ore deposition, the geologist gives a key to the unraveling of the complexities of ore distribution. The key does not always fit the case but the difference between intelligent and unintelligent observation constitutes the great gift of geology to mining. "Without speculation there is no good and original observation," so said the author of 'The Origin of Species'. Theories come and go, but the multiplication of facts tends continually to furnish a safer basis for the ascertainment of ultimate truth. We have learned from Le Neve Foster, from Judd, from Huxley, that "we ought to exhaust known causes before seeking for the explanation of geological phenomena in causes of which we have no experience;" and we are impressed by a "conviction of the unbroken sequence of the order of natural phenomena, throughout the duration of the universe, which is the great, and, perhaps, the most important, effect of the increase of natural knowledge." So said Huxley. This conviction has guided the economic geologist; he has gone from the known to the unknown, from the present to the past, from the volcano in eruption to the solidified lava veining the rocks, from the hot spring bubbling at the surface to the fossilized vent that was once a thermal conduit, from the solution observed by him in his laboratory to the underground solutions whose activities formed the gold vein. Thus illumination has been given to the miner. No longer he gropes blindly in the darkness underground, for science has given him a light, feeble it may be as his candle in the gloom of cavernous workings, its rays do not reach far, they will not penetrate the rock, but at least they keep his feet from stumbling and his hands from misdirected labor. That is the gift of geology to mining.

COSTS AT THE ESPERANZA MINE

Written for the MINING AND SCIENTIFIC PRESS
By W. E. HINDRY

Considerable pains were taken to acquire reliable data with reference to labor and material per lineal metre of opening in various classes of development work done in the different kinds of ground found in the Esperanza mine, and also the progress and costs of shaft sinking at varying depths. These data have been tabulated and the results are given opposite. The first set of figures shows kind of opening, character of ground penetrated, total distance driven, average daily progress, condition of ventilation, whether hand or machine work, supplies consumed per lineal metre, and labor required per lineal metre, while the second statement shows the costs per lineal metre of two shafts sunk on the Sirio and Suceso properties of the Esperanza Mining Co. in 1899 and 1902, the unit cost of labor and supplies obtaining at that time being also appended in order that comparisons can be made with similar work under different conditions as regards these last items. An account of the methods of work at this mine has been given in the MINING AND SCIENTIFIC PRESS, December 18 and 25, of last year.

DEVELOPMENT DATA, ESPERANZA MINE, EL ORO, MEXICO, 1901.

Description.	Wide, ft.	High, ft.	Character of ground.	Total distance driven, metres.	Average daily advance, metres.	Ventilation.	Hand or machine work.	Supplies per lineal metre. Powder, kegs.	Fuse, metres.	Caps, number.	Candles, number.	Labor, per metre. Miner, shifts.	Peon, shifts.	Remarks.

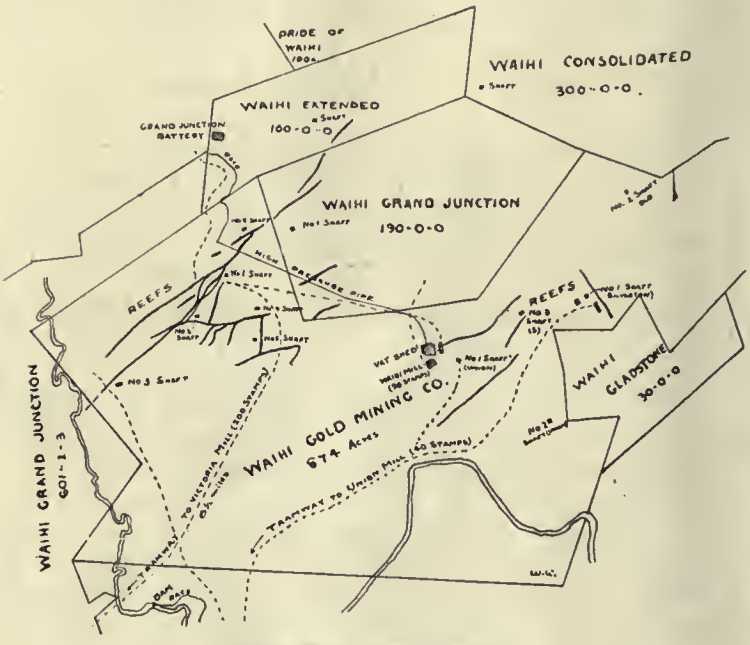
Gold and Silver Mining in New Zealand

By W. Wilson

*The mining of gold dates from a very early epoch in the history of New Zealand. It was in 1852 that the first gold was found in the Auckland province, and since then many fortunes have been made in the Dominion. In 1907 over £2,000,000 worth of gold was exported, of which more than half comes from Auckland. The rest is derived from two other gold-producing areas—Westland and Otago. In the north the metal is from quartz-mining solely, while in the two southern fields alluvial mining and dredging are also utilized. By far the best property is the famous Waihi mine, in the Ohinemuri hills of Auckland, which yields steadily about £70,000 worth per month. Adjoining Waihi is the Karangahake district, with many wealthy claims, of which the Talisman, producing £184,445 in 1907, and the New Zealand Crown Mines, producing £57,242, are the most important. The Komata Reefs company yielded £47,128, and the Thames district, in the same neighborhood, contains a number of mines that have produced phenomenally rich yields. The Waiotaki gave £149,833 in 1907, and besides this there are the May Queen, Kuranui-Caledonian, and others. In the south gold-winning is proceeding vigorously in Westland, where advances are being made just at present. The Progress mine, and the Keep-it-Dark, at Reefton, are the chief quartz-mines, the former yielding £87,805 worth in 1907. The Mont d'Or claim, at Ross, is an extensive sluicing property, while gold is obtained from the rivers of this district and of Otago by means of 165 dredges. The Clutha river, in the southern province, is a huge natural sluice-box and the scene of great dredging industry. A total value of £620,900, mostly obtained from dredges and small sluicing claims, came from Otago and £381,874 from Westland in the same period.



Waihi Mines, New Zealand.

With regard to future extensions of the industry, there is every evidence of abundance of metal untouched. This is particularly the case in Auckland, as will be seen when an inspection of the existing sites is made. At Waihi there is much undeveloped land of great promise adjoining the Waihi Gold company's mine. This enterprise is famous throughout the world for its productiveness, as a venture which steadily pays dividends of 85 and 90% deserves to be. Its success has been due to the discovery of the cyanide process for treating low-grade ores, a method originating from this country. A map of the region is shown. Every indication points to the rich reefs extending into the adjoining properties, notably the Waihi Grand Junction. The investment of more capital in the near future will almost certainly prove this to be the case. At the Thames new extensions are about to be made beneath the present levels. Up till now the workings have been comparatively shallow, as it was believed that gold could not exist at a depth of 1000 feet.

However, good ore is now obtained at Bendigo, in Victoria, at depths of 3000 and 4000 ft., and at Reefton, in Westland, the Wealth of Nations Co. obtains good ore at a depth of 1775 ft., and is at present sinking to a further depth of 125 ft. The formation of the Thames reefs indicates their presence at greater depths, and though want of capital is checking enterprise at present, there should be a great future before the Thames Deep Levels. In Westland growing enterprise is accomplishing good results. The whole province is a proclaimed goldfield, and much gold exists that yet awaits working. In September 1909, a hydro-electric plant of 2000 hp. has started work at Ross. In Otago gold is produced over a wide area, and is worked almost entirely by dredging and sluicing. The total production is high, but the prospects of extensions are not so bright as in the northern fields.

Silver is found accompanying gold in many places, such as Waihi. In 1907 over a million and a half ounces was mined. Copper occurs in thirty-one known localities altogether but is richest in Nelson and Auckland. Small quantities have been worked at various times, such as 351 tons in 1858 and 245 tons in 1859; but for want of systematic prospecting, not sufficient ore has been developed to warrant extensive outlay. A heavy lode of copper pyrite, with native metal, is at the present time being worked near Nelson City, and a syndicate has just begun smelting operations in Auckland.

Aside from these metals others are present. Iron ore may become one of the most valuable resources in New Zealand. This consists of two varieties, the Taranaki iron sand and the Parapara deposits, in the Nelson district. The former is a black, titaniferous, magnetic ore, present in quantity on the sea-shore. Owing to its finely divided condition, smelting by existing processes has not been commercially possible, although briquetting was

*Abstract from 'Natural Resources of New Zealand', *Cassier's Magazine.*

tried for some years. A successful process is being sought. Quantities have been exported to Germany for reduction by the electrolytic process, for which this ore is exactly suited. The Parapara deposit is of comparatively recent discovery in the Nelson province, and forms a stratum 100 ft. thick, exposed over several acres. It is less than half a mile from the sea-front, and is in the immediate vicinity of coal, limestone, and water-power, so that it would seem to be particularly valuable. The ore is pure hematite mixed with quartz pebbles, and contains 40% iron. Nine other fairly large deposits of iron are known and none are at present worked to any extent.

Tonopah Extension Mill

Written for the MINING AND SCIENTIFIC PRESS
By JOHN G. KIRCHEN

The new mill of the Tonopah Extension Mining Co., at Tonopah, Nevada, has but recently been started. A brief description of the machinery and arrangement of the plant is given below.

The ore from the mine is dumped direct into a No. 4 Kennedy crusher, placed on top of an ore-bin. This bin is 15 by 15 ft. inside. The crusher is driven by a 30-hp. Westinghouse motor, 900 r. p. m., 9-in. pulley. The ore is crushed to about 1½ in. The ore-bin discharges through an 18 by 24-in. rack and pinion gate to the belt of a 16-in. troughed incline belt-conveyor, and is thus carried to the top of the battery-bins. The conveyor is driven by a 7½-hp. motor 1120 r. p. m. The distributor on the battery-bins is driven by a 5-hp. motor 1120 r. p. m. The incline distance of the conveyor is 235 ft., the total rise being 40 ft. The above crusher and conveyor were furnished by Chalmers & Williams.

The battery-bins are of wood, and are an integral part of the mill-building. They are 13 ft. wide, 15 deep, 50 long, and have a flat bottom. The inside of the bins, at the ore-bin gates, is protected from the usual wear by means of 16-lb. rails, spiked vertically on the battery-side of the ore-bin. The bins are double-floored with building-paper between, protecting the mill from dust.

The battery ore-bins feed through six 18 by 24-in. rack and pinion ore-bin gates into suspended Challenge feeders, and thence into mortars. The mortars are of the modified Homestake type with extra wide base for setting on concrete foundations. The casting is 12 in. thick under the dies, and weighs, with liners, about 9500 lb. Each stamp weighs 1050 lb., and makes 98 drops per minute. There are 30 stamps, in batteries of 10 each, with 5 stamps per mortar. Every group of 10 stamps is driven by a 30-hp. Westinghouse motor, running 690 r. p. m., placed under the ore-bins and driving the drive-shaft by means of an 11-in. endless double leather belt. The battery drive-shaft is 3 in. diam. The cam-shaft is 5⅞ in. diam., with drive-pulley of wood, 72 in. diam. by 17 face. The belt is 16-in. 5-ply rubber, with a swinging triangular-frame battery-belt tightner. The stems are 3⅜ in. diam. by 15 ft. long. The cams are keyed to the shaft by Blanton patent fasteners. The complete stamp-battery was furnished by the Union Iron Works of San Francisco. The mortar block is of concrete, reinforced with 6-in. flat iron hoisting cable, the oil and grease on the cable having first been removed by heating.

The pulp from each battery of 10 stamps flows to two Deister concentrators, where the coarse concentrate is removed. The six Deister concentrators are driven by a 5-hp. Westinghouse motor, 1120 r. p. m. The tailing flows direct to two Dorr classifiers. The classifiers are sheet-steel tanks 4 ft. 6 in. wide by 16 ft. long, with a bottom slope of 2 in. per foot. Inside are a series of rakes set transversely, which move back and forth, pushing the coarse pulp to the top, and lifting clear of it on the return motion by means of a cam and rocker arm. The slime and surplus water overflow at the lower edge of the tank. The classifiers are operated by a 5-hp. Westinghouse motor 1120 revolutions per minute.

The coarse pulp from the Dorr classifiers is fed direct to two 5 by 18-ft. trunnion-type tube-mills, with scoop feed. These mills were built by the Traylor Engineering Co., and are lined with El Oro liners, cast in blocks about 21 by 16 in., with ribs about 1½ in. thick projecting 3 in. and leaving a space between the ribs of about 3 in. These blocks are bolted to the shell. The two tube-mills are driven by a 100-hp. Westinghouse motor, 690 r. p. m. The motor belt is of double leather, 14 in. wide, connected with the main shaft from which clutch-pulleys operate the tube-mills separately. The tube-mill belts are of 6-ply rubber, 14 in. wide.

The tube-mills discharge direct to hydraulic classifying cones where, with the assistance of the solution and slime-overflow from the Dorr classifiers, the coarse particles are removed and the thin slime-pulp is delivered to three 8 by 54-in. Frenier sand-pumps. A feature here worthy of special mention is the tube-mill floor, which is made of concrete and is sloped to a central pit where all leakage finds its way, and where, together with the coarse particles from the hydraulic classifiers, it is elevated by means of a bucket-elevator, and returned to the Dorr classifiers for re-treatment. The Frenier sand-pumps elevate the slime to six 8-ft. Callow cones. The overflow from these cones goes direct to the mill solution-tank, while the thickened pulp is distributed over 12 Deister slime concentrators. These 12 machines are operated by a 10-hp. Westinghouse motor running 1120 r. p. m. The slime tailing is run to a central sump and is pumped to slime collecting tanks. The pump used is a 7 by 9-in. Aldrich triplex slime-pump. A 15-hp. Westinghouse motor running 1120 r. p. m. is used to operate the three Frenier sand-pumps and the Aldrich triplex pump.

There are four slime-collecting tanks 24 ft. diam., 16 ft. high, having a false conical bottom 25° slope toward the centre. These tanks are fitted with overflow launders and decanters. Arrangements are such that the clear solution can be discharged either to the mill-tank or the gold-tank, depending on the gold and silver the solution contains.

The thickened pulp from the slime-collecting tanks is pumped into either of the three agitating tanks by means of a 6-in. Krogh centrifugal slime-pump, operated by a 10-hp. Westinghouse motor, 1120 r. p. m. Here the solution is brought to its proper cyanide strength. These agitating tanks are 24 ft. diam. and 16 high, and represent the latest development in agitation and aeration of cyanide solution and pulp. It is known as the L. C. Trent Shoshone agitator and aerator, and works on principles that are both unique and effective. It is operated by drawing off the liquid and thin slime from the top of the tank containing the agitator and with a centrifugal pump forcing same through a central pipe to near the bottom of the tank. This central pipe has four arms or pipes radiating from it. These arms are fitted with short jet-pipes or nozzles inclined downward toward the bottom of the tank and through

which all the solution and pulp drawn from the top must pass. The pressure of the solution and slime discharging through these restricted nozzles causes the arms to revolve at a speed sufficient to thoroughly stir and agitate. Air is admitted to the suction through a small valve and is introduced into the pump and forced into the solution; resulting in a complete admixture of air, solution, and slime. The solution readily becomes charged with microscopic air bubbles and the top of the tank presents a seething effervescent surface.

The feature that permits of the economic operation of this machine is the patent grit-proof step-bearing. The action of this device is such that as the tank is being filled with slime and solution, air is automatically imprisoned in an inverted chamber that surrounds the step-box, and the liquid and solid in the tank are excluded from the bearings which are maintained free from solution and slime, so that friction is no greater than were it not submerged. Numerous experiments have been made by stopping the agitator and allowing the slime to settle several hours. In each case the arms revolve within a few minutes after starting the agitator. The wear on the pump is light, owing to the fact that only fine slime and solution are drawn through it, while the coarser particles are held in suspension in the tank by the constant rising currents. Each agitator is operated by a 10-hp. Westinghouse motor, 1120 r. p. m. driving a 5-in. Price centrifugal slime-pump. The actual power consumed has not yet been determined, but it is safe to say it will be much less than the capacity of the motor. It is claimed for this agitator, that a much higher extraction is obtained, with less time for agitation and a low power-consumption. These are manufactured by the Trent Engineering Co., of Los Angeles. The pulp from the agitators is pumped to a large storage-tank with the same pump as is used to charge the agitating tanks. This storage tank is 30 ft. diam. by 20 high. The pulp is agitated and kept in suspension by an agitator similar to those above described. The important difference is that in this case the agitator is of the under-feed type, the agitating arms revolving on ball-bearings. The solution is drawn from the bottom of the storage-tank to the Blaisdell filters by gravity.

The filter-tank is constructed of steel having five hopper-bottoms. There are 100 leaves 5 by 10 ft., made of canvas-covered grooved wooden strips, similar to the Butters filter-leaf, with the exception of the cocoa matting. The bottom of the tank is so constructed that each set of 20 leaves discharges the washed pulp throught a separate hopper connected with an outlet-pipe which carries the slime to the main sluice-launder. In this department there are two more tanks placed above the filters, one being used for weak-solution, and the other for wash-water. These tanks are both 26 ft. diam. by 8 high. The vacuum for the filters is furnished by a Knowles 10 by 10-in. vertical pump. There is also an 8-in. Krogh centrifugal slime-pump, which is used to return the excess of slime from the filter-tank back to the storage-tank.

The solutions from the filters run direct to the gold-tank, which is 30 ft. diam. by 8 high, and thence to a long wooden box 4 ft. square, filled with excelsior, which serves to remove any fine slime from the solution. The overflow from this clarifying box goes direct to the zinc-boxes, of which there are eight, each having six compartments. These boxes are constructed of steel, each compartment being 3 ft. long, 31 in. wide, and 32 in. deep, with a hopper-bottom under each compartment, over which a screen with ¼-in. mesh is placed to retain the zinc. Short-zinc will be transferred toward the head-compartment at each clean-up.

The barren solutions run to two sump-tanks 26 ft. diam. by 8 high, and is then pumped to the main mill-solution tank by a 5 by 6-in. Aldrich triplex-pump, operated by a 10-hp. Westinghouse motor, 1120 r. p. m. This motor also drives a smaller size of pump, which is used as an auxiliary. From the mill-tank, the solution is pumped by a 6 by 9-in. Aldrich triplex pump, operated by a 7½-hp. Westinghouse motor, 1120 r. p. m. to a 24 by 15-ft. mill-tank, which is situated above the batteries.

The silver and gold precipitate is sluiced from the hopper-bottom of the zinc-boxes to two tanks, 4 ft. deep by 10 diam., provided with false-bottoms of cloth over slats, which act as filters. Connection is made under the filter to the 5 by 6-in. Aldrich auxiliary pump, which serves to filter the precipitate and return the solution to the zinc-boxes.

The gold and silver precipitate is shoveled out and delivered to a steam dryer. This is a jacketed steam-box constructed of ⅜-in. steel-plate, the inside dimensions being 6 ft. wide, by 15 long, and 14 in. deep. Four inches of this depth is used as the steam-jacket. After drying, the precipitate is mixed with borax and melted in an oil-fired No. 275 Monadnock steel Harvey furnace.

The mill is run three shifts of 8 hr. each; one man is employed on each shift on the batteries and also attends the electric-driven air-compressor which supplies air to the mine; one man looks after the tube-mills, Callow cones, and Deister slimers; one solution-man to look after the agitators and solution-tanks. The filters are also attended by one man on each shift. On the day shift a roustabout, a man to attend the zinc-boxes and clean-up, is employed; these, with the mill superintendent, make a total force of 15 men.

The mill-building is a frame structure covered with corrugated galvanized iron, everything being under one roof. The site is such that the transportation of materials by gravity is not allowable in all cases, but the pumping has been reduced to a minimum, as the description shows. Electric power is supplied to the motors throughout the plant at 400 volts, by the Nevada-California Power Co. All the tanks used in the mill are of redwood, manufactured by the Pacific Tank Co. The mill is designed for a capacity of 120 tons per 24 hr. The material treated is a complex silver-gold ore carrying approximately 90 oz. silver to 1 of gold. In designing the mill I was assisted by Fred M. Field. J. P. Montague is the present mill superintendent.

Magnesium chloride and sulphate in water have a deleterious effect upon cement.

Plotting Co-ordinate Surveys

Written for the Mining and Scientific Press
By J. J. Bristol

(*Continued From Page 490.*)

The application of the protractor is best understood by considering a practical example of a stope-survey. In connection with this example the determination of dip and areas will be discussed. Suppose the notes of two successive surveys of the stope 17 on 1 are as follows:

Stope 17 on 1 West. Under 1701 A. Backsight 1701.

15b	157°40′	125°20	85.1	49.5

To plot 17 on 1 West, Survey A, draw a line through 1701 A and 1701 (as in this instance the two stations are very near together it is best to extend the line as previously discussed in the plotting of drifts), place the protractor on the plan with the needle *I* pressed down through 1701 A, and then revolve until 204°40′ black, if line extending through backsight is used, or 204°40′ red, if the line extending from backsight through and beyond 1701 A is used; then move the scale *C* until 123° is indicated on *B*; then scale *D* until its graduated edge indicates 105.9 on the scale *C*; the needle *H* is then pressed down and a point marked on the surface of the paper. The vertical distance to be used later in the determination of the angle of dip, is read off on scale *D* and recorded opposite the station number to which it belongs. All the other points are plotted similarly, and the vertical distances recorded. The vertical distances above recorded have been read off from the protractor, and with a few exceptions will be found to agree with the calculated distances to 0.1 ft.; the exceptions to 0.2 ft. The points thus plotted for each survey are joined by right lines, inked in, thus showing the horizontal projection of the contour of the face of the stope for each survey (see Fig. 9). The freedom of the plan from pencil marks and lines is here noticeable; no erasures being necessary. As the data are not at hand and as the area stoped has no connection with the upper and lower drifts, they are not indicated on the plan of the stope shown in Fig. 9.

Before discussing the determination of dip it would, perhaps, be as well at this point to explain the use of the two sets of figures, red and black, on circle *A*. If, when plotting a stope, the line drawn through the backsight would place the protractor in a less convenient position to use, by extending the line in the opposite direction and without altering the horizontal angles as read, the red set of figures would be used and the plotting proceeded with as before. This has been done in the plotting of the stope above. Also, when making the underground survey, sometimes owing to the nature of the stope it is more convenient to read vernier II than vernier I; in this case the angle is recorded as read from vernier II and when plotting, if the line through the backsight is being used as the reference line, the red set of figures is used; if the line extending in the opposite direction, the black figures. And again it is sometimes necessary to transit the telescope to be enabled to read the vertical circle; in this case, if using the line through backsight vernier II would require the black, and vernier I the red, and if using the line extending in the opposite direction, vernier I black and vernier II red. The vertical angles would

have to be changed, depending on how the vertical circle was numbered and on the position of the verniers.

Assuming that the strike and the dip for the stope above plotted are uniform, no considerable error, considering the irregularities of the trend of the stope-face, will be evidenced if it is assumed that the line of strike passes through a point in 17 on 1 East, Survey B, the elevation of which is the same as the elevation of a point in 17 on 1 West, Survey B. For this assumption the point 8b in 17 on 1 West, at a vertical distance 25.7 below horizontal axis of instrument and a point in 17 on 1 East halfway between points 7b and 8b the mean of whose vertical distances below the horizontal axis of the instrument is 25.7, and hence the elevation of the assumed point, will suffice. A line drawn through these two points is the line of strike which, while not the true line of strike, as will develop later, is near enough for practical purposes. At any convenient point draw a line at right angles to the line of strike; on this line project the points plotted; then lay off at right angles to this line from each projected point the vertical distance belonging to that point; join the points thus determined. The contour thus formed is the line of dip (see Fig. 9).

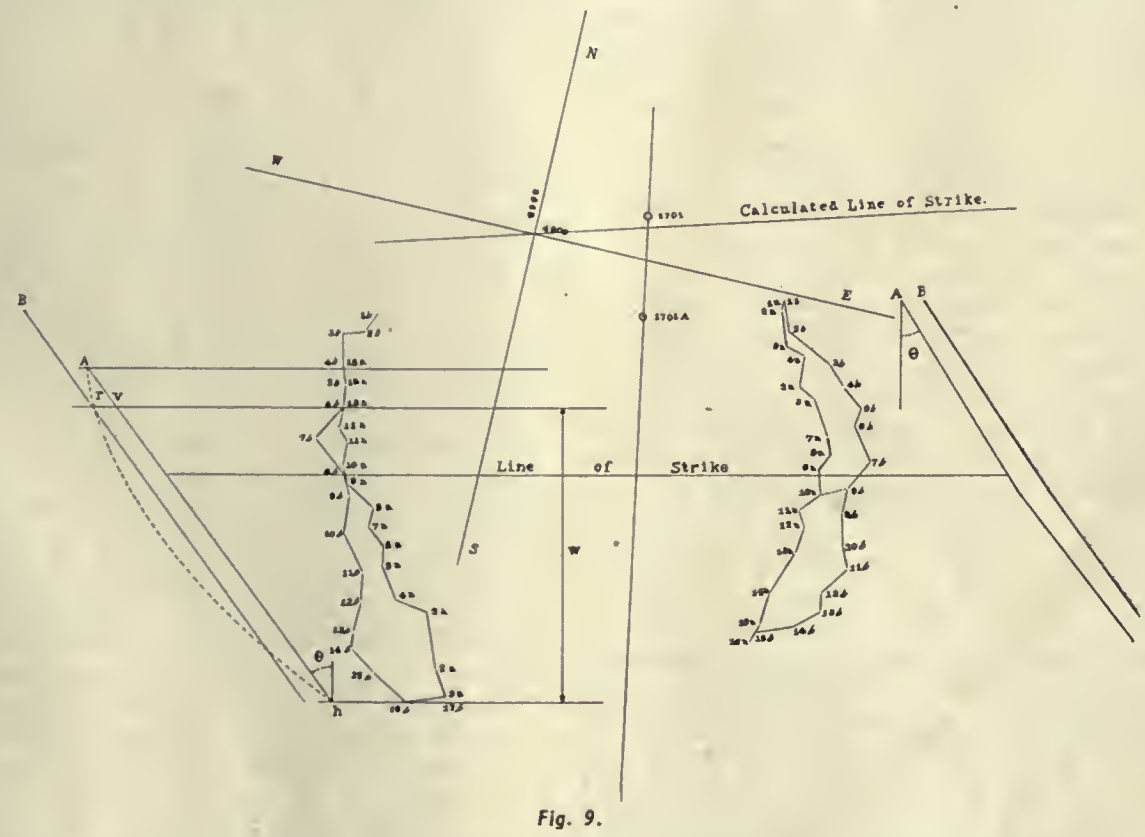

Fig. 9.

It is preferable to transfer the projected points to a separate paper, and lay off the distances thereon. Thus the dip-lines for each survey will not be confused with the stope-contours.

In the dip-contour of 17 on 1 East, Survey A, the points from 1a to 10a are practically on the same line of dip; at 10a the dip changes, and from 10a to 16a the points are on the same dip-line. In the dip-contour of 17, on 1 East, Survey B, the points from 1b to 8b are on the same line of dip; at 8b the dip changes and the points from 8b to 15b are on the same dip-line. The angles of dip are then taken off with a protractor, and in the order mentioned above are 30°30′, 36°30′, 33°30′, 35°00′. Draw a line from 10a to 8b, dividing the area into two parts. To determine the slope-area of the upper one multiply the horizontal area by the secant of 32°00′ (the mean of the two dip-angles for that part of the stope) of the lower one, multiply by the secant of 35°45′ (the mean of the two dip-angles for that part of the stope). The sum is the slope-area stoped. In the stope 17, on 1 West, Survey A, the points are practically on the same line of dip, which is determined to be 35°45′. For Survey B the dip is found to be the same. The area is found as before. As the stoping surface in 17, on 1 East, is a warped surface, the more accurate method would be to find points in contour 17, on 1 East, Survey B, at the same elevation as those in contour 17, on 1 East, Survey A, assuming that the change of dip between any two consecutive points is uniform, and then draw lines through points of the same elevation. These lines will be the lines of strike at those points; then taking the mean of any two strike-lines as the line of strike for the area between those two lines and the mean dip as determined by projecting the points, and laying off vertical distances as before, the slope-area is determined for that part of the stope. The areas of the remainder of the stope are determined in the same way, and the sum of the whole is the area stoped. For small areas, and where the stope is slightly warped, the difference of area is inappreciable. If the stoping surface is considerably warped the difference of area is considerable, and an application of the preceding method, or one of the following, is necessary for a precise determination of the slope-area.

In the case where the line of strike is constant, and the dip variable, and hence the contour of the line of dip is a curved line, to find the slope-area plot the

stope as before, and upon determining the line of strike plot the dip-line, and either divide the horizontal area into several parts, taking the dip off the dip-line for each part, find the slope-area for each part, the sum of the several areas being the area of the whole; or find the horizontal area and the horizontal length of this area, measured at right angles to the line of strike, between the line of strike through the uppermost point of the horizontal area and the line of strike through the lowest point of the area; divide the area by the length, giving the average width of the horizontal area, multiply this by the length of the dip-line between the two dip-lines, giving the area stoped. For example in 17, on 1 West, draw the line of strike through 6b and 16b, measure the distance *W* between them, divide the horizontal area by this length, giving the average width, multiply this by the length of dip-line *vh*, giving the slope-area (see Fig. 9).

The line of strike and the angle of dip may be determined as follows: the co-ordinates of 1701 and 1701 A being

	X.	Y.	Z.
1701	6922.16	4891.28	1164.84
1701A	6925.89	4911.44	1178.67

then by calculation the co-ordinates of the points 2a, 3a, 12b, and 15b, in stope 17, on 1 West, are

	X.	Y.	Z.
2a	6900.88	4992.43	1235.32
3a	6896.41	4981.37	1226.92
12b	6882.62	4982.51	1224.92
15b	6888.40	4996.09	1235.72

Changing the origin of co-ordinates, to facilitate computations, to $x = 6880$, $y = 4980$, and $z = 1220$, the co-ordinates of the above points become:

	X.	Y.	Z.
2a	20.88	12.43	15.32
3a	16.41	1.37	6.92
12b	2.62	2.51	4.92
15b	8.40	16.09	15.72

Find the equation of the plane containing any three of the above points; then the interseetion of this plane and any horizontal plane will be the line of strike, and the angle between the two planes the angle of dip. The general equation of the plane is $Ax + By + Cz = D$. First taking the points 3a, 12b, and 15b, substituting the values of x, y, and z in $Ax + By + Cz = D$, solving for B, C, and D, in terms of A, substituting the values thus found in $Ax + By + Cz = D$, the equation of the plane is found to be $x + 3.4802y - 4.9118z = -12.808$. Substituting $z = 0$, the equation of the line of stroke is $x + 3.4802 = -12.808$. Solving for y, $y = -x \div 3.4802 - 12.808 \div 3.4802$. Whence tangent $\Phi = 1 \div 3.4802$ $\Phi = -16°00'$. Hence the strike is N.74°00'E. The angle of dip is given by Cosine $\Theta = AA' + BB' + CC' \div (A + B + C)^{\frac{1}{2}}$ $(A^1 + B^1 + C^1)^{\frac{1}{2}}$; A, B, C, and A^1, B^1, C^1, being the coefficients of x, y, and z in the equation of the plane $x + 3.4802y - 4.9118z = -12.808$ and $z = 0$ respectively. Making the proper substitutions and solving, the angle of dip is found to be $\Theta = -36°24'$.

Again taking the points 2a, 3a, and 12b the equation of the plane is found to be $x + 3.37254y - 4.97265z = -13.27081$. Whence $\Phi = -16°31'$. Hence the strike is N.73°29'E. The mean strike is N.73°44'30" E. The angle of dip $\Theta = -35°17'$. The mean dip is 35°50', which is nearly in agreement with the angle of dip previously found.

The discrepancy in the two determinations of the angle of dip is due to the points sighted at being slightly above or below the true line of dip, thus causing a slight error in the vertical distances, which when introduced into the equation of the plane produces a slight difference in the coefficients of x, y, and z; this difference causing considerable difference in the determinations of Cos. Θ by the above formula. While a difference of half a foot in elevation is not very noticeable in the plotting of the dip-line, it is quite so when used in the above formula, as is evidenced by the discrepancy in the two angles of dip.

That the points sighted at must, to ensure accuracy, be chosen precisely half way between the hanging and foot-wall, or on the line of trend of the stoping face, is evident. If the points are carefully chosen then the probability is that they are all equally in error, and therefore the mean of two determinations should be taken as the true dip.

The direction of the line of strike is somewhat different from the one assumed, but not enough to cause an appreciable difference in the determination of the dip by plotting the vertical distances parallel to the assumed line of strike. This difference is explained by the fact that the east side of the stope dips less than the west side so that the point between 7b and 8b east side would at the same dip as the west side be higher up the stope; thus the assumed line of strike would have more nearly approached the calculated line of strike.

Another method of determining the dip, if the foot or hanging wall of the stope is of uniform dip, is by taking sights to three points on either hanging or foot-wall, two in one line on one side of the dip-line and one on the other side, reading the horizontal angles, the vertical angles, and the slope-distances.

The form of the notes and the formulae are as follows:

Inst.,	Un., B.	B. S., A.	F. S., x_1, x_2, x_3.		
	Hor. angle.	Ver. angle.	Sta. dist.	Ver. dist.	Hor. dist.
x_1	$\Phi_1°$	$\Theta_1°$	S_1	a	d
x_2	$\Phi_2°$	$\Theta_2°$	S_2	b	e
x_3	$\Phi_3°$	$\Theta_3°$	S_3	c	f

$\Phi_3 - \Phi_1 = 90°00'$. Bearing A to B $= \Theta°$. If $\Phi°$ is the angle made by the line of strike with the line x_1, x_2, then Tan. $\Phi = f(b - a) \div [e(c - a) - d(c - b)]$. Hence knowing Θ and Φ the bearing x_1, x_2 can be found and then the bearing of the line of strike. Tan. angle of dip $= (b - a) \div (e - d)$ Sin Θ.

As a practical example; bearing A to B S. 30°20'W.

	Hor. angle.	Ver. angle.	Sta. dist.				
x_1	175°40'	140°00'	17.0	a	13.0227	d	10.9273
x_2	175°40'	135°00'	31.5	b	22.2738	e	22.2738
x_3	85°40'	122°00'	36.0	c	19.0771	f	30.5297

Whence, bearing x to x is S.26°00'W. $\Phi = 59°01'$. Hence, bearing of line of strike is N.85°01'E.; and the angle of dip is 43°35'.

The slope-area may be found without either finding the angle of dip or the line of strike, as follows: divide the area into triangles as 1a, 2a, 16b; 2a, 16b,

15b; 2a, 15b, 14b; 2a, 3a, 14b, and so on (see Fig. 9, 17, on 1 West), then use the formula.

$$\text{Area} = [s(s-a)\ (s-b)(s-c)]^{1/2}\ s = \tfrac{1}{2}\ (a+b+c).$$

$$a = [(x-x_1)^2 + (y-y_1)^2 + (z-z_1)^2]^{1/2}$$

$$b = [(x-x_2)^2 + (y-y_2)^2 + (z-z_2)^2]^{1/2}$$

$$c = [(x-x_3)^2 + (y-y_3)^2 + (z-z_3)^2]^{1/2}$$

$x, y, z; x_1, y_1, z_1; x_2, y_2, z_2$

being the co-ordinates of the vertices of the triangles. The fault of this method is that it requires numerous calculations of co-ordinates, although the labor could be shortened by taking the co-ordinates of the points, as plotted with the 'plotting protractor', off the plan, and using the vertical distances given by the 'plotting protractor'.

Stopes on a conical surface are plotted as before, the dip and slope-area determined, considering the stoping surface as plane; the error in so doing being inappreciable except when the radius of the base of the cone is small; in which case the surface may be developed according to the principles of descriptive geometry.

It will be noticed that the dip, as plotted, changes abruptly at 10a, 8b. Actually this is not the case, as there is no slip or fold at 10a, 8b. Probably the points between 1a and 10a, and 10a and 16a, have been chosen slightly below their true positions and hence the dip-lines are curved. The slight difference in the slope-area is inappreciable.

Sometimes, although the pay-streak or leader or vein being stoped, preserves its continuity, it may be carried near the hanging or the foot-wall at the time of one survey and at the next survey may be on the opposite wall. This would modify the strike, and hence the angle of dip and the slope-area stoped. In a case of this kind the points sighted at instead of being chosen half-way between the hanging and the foot-wall should be on the pay-streak or leader or vein, irrespective of its position in relation to the two walls. This is again modified in case the stope is on contract, depending on whether the contractor has strayed off the leader, or owing to a change in the walls has been ordered to change the position of the stoping face. If the contractor has erred, then the sights should be taken on the pay-streak or leader; if not, on points half-way between the hanging and foot-walls. In either case, the horizontal plane is the same, the slope-area only varying.

In the stope 17, on 1 East, the assumed line of strike has been used in the determination of the angle of dip. Perhaps a better plan would be to take a point 6a, and find the point at the same elevation between 4b and 5b, drawing a line through 6a and the point found, giving the line of strike, and then finding the dip; find the slope-area for that part of stope 1a, 10a, 8b; and also the point 13a; finding a point between 10b and 11b at same elevation as 13a, the line of strike and the angle of dip and slope-area as before of that part of stope 10a, 8b, 15b; the sum of the two areas thus found giving the area stoped.

In an earlier paragraph the method is discussed as though the line *rh* were a curved line, which is not the case. If the line were curved as *rh* (see dotted line, Fig. 9) the length of *rh* would be found with an opisometer, and the average width of the horizontal area, multiplied by the length found, giving the slope-area.

In the stope 17 on 1 for another successive survey the mean of the dip-line then found and the dip-line of the preceding survey would be the dip-line to be used in finding the angle of dip and thence the area stoped. If the line of strike were altered in direction in the successive surveys then the vertical distances of the preceding survey should be laid off parallel to the new line of strike (from the projected points of the contour of the face of the stope at the preceding survey) on a line at right angles to the line of strike.

ORE DEPOSITS AT BULLFROG

A report on the geology and the ore deposits of the Bullfrog mining district, in Nye county, Nevada, by F. L. Ransome, W. H. Emmons, and G. H. Garrey has just been published by the United States Geological Survey as Bulletin 407. The district is a tract of arid hills and mountains lying northwest of the Amargosa desert and including about 21 sq. mi. The principal town is Rhyolite, which is 60 miles south-southeast of Goldfield and about 85 south-southeast of Tonopah. The other towns are Beatty and Bullfrog.

Long before valuable ores were discovered at Tonopah and Goldfield the springs in Oasis valley, just north of the site of Beatty, attracted a few wanderers, who established rude ranches along Amargosa river. In 1904 the Bullfrog claim was located. The name is said to have been suggested by the green color of the ore; certainly no one has found in that scorchingly arid region anything resembling a bullfrog. In a few months the towns of Amargosa City, Bonanza, Bullfrog, Beatty, and Rhyolite rose from the desert sands and mining was actively begun, but until 1907 only the richest ore was shipped from the region, for lack of satisfactory means of transportation. In 1907 three lines of railroad reached the district, and during that year the value of its mineral output was $207,538, principally in gold and silver.

The deposits of the Bullfrog district, unlike those at Goldfield, are not likely to yield quick and large profits with a moderate outlay of capital, though small masses of superficial ore may for some time reward a few fortunate lessees. The ores generally are of low grade and the question whether the deeper sulphide ores can be profitably mined is still unanswered.

The North American Lead Co. has a large reduction plant running on copper, nickel, and cobalt ore and is producing electrolytic copper and nickel and cobalt oxide. Great quantities of this ore are now known to exist in Missouri, and no doubt in the future this district will be a producer of these metals.

Alkaline tannates are efficient in boiler water treatment. They act by separating the alkaline earths in a light precipitate that remains in suspension and does not form scale. In their use there is not the danger of corrosion that may occur when tannic acid is used alone.

Southeast Missouri Mining

Written for the MINING AND SCIENTIFIC PRESS
By S. S. CLARKE

The lead, copper, nickel, and cobalt ores of southeastern Missouri are disseminated through the magnesian limestones of the Bonne Terre formation of the middle Cambrian period. The mineral zone follows the plane of the limestone bed overlying sandstone and granite. The ore is found principally in the bedding planes of the dark colored limestones, and disseminated in fine grains through the more porous limestone. Crystallized minerals are found in cavities and mud channels. A few instances have been noted where the ore has penetrated the sandstone several feet. In two headings of the Madison mine as the ore approached the granite rim of the basin (in which the mine is situated), the galena was replaced by iron pyrite. This gave way in turn to chalcopyrite and siegenite. At the mine of the North American Lead Co., galena has been almost entirely replaced by copper, nickel, and cobalt sulphides, which occur as chalcopyrite, siegenite (nickel linnaeite), and absolite. Lead occurs mainly as non-argentiferous galena. Some cerussite is found in the clay overlying the limestone. The depths of the shafts vary from 70 to 250 ft. Nearly all diamond-drill holes and shafts bottom on the sandstone. The ore is mined by underhand stopes, the height of the back varying from column high to 40 ft. Timbering is not required as the back is good and pillars are left from 20 to 25 ft. apart, depending on conditions of the ground. The ore is roughly sorted underground, about one ton of waste being sorted out for ten tons of ore. The average efficiency of the underground work is 21 tons broken per drill and 18 tons loaded per shoveler. At present the average wages are $1.80 per 8-hr. shift for machine men and shovelers. One-man drills are usually run on contract at 6c. per foot.

The general practice of milling followed is dry-crushing, using gyratory or Blake type of crushers, breaking to 1½ in., screening through revolving screens with ½-in. perforations, oversize to 14 by 36-in. steel-shell rolls. The product of the rolls and the undersize from the first screen are elevated to a 10-mm. (one section being 3-mm.) revolving screen; oversize goes to 14 by 30-in. Joplin type rolls and returns to feed; 10-mm. stock from screen goes to a vortex type of classifier, 3-mm. feed and overflow from classifier flows to trough hydraulic classifiers. The discharge from first classifier goes to a Hancock jig, the lead concentrate being discharged in the first hutch; a mixture of lead and copper; nickel and cobalt are discharged in the second hutch; and copper, nickel, and cobalt in the third. The product of the second hutch is re-ground and sent to the tables. If the lead predominates in the ore as sometimes it does, it is then necessary to re-grind the third hutch product; if the lead is low the second hutch product is usually clean enough to be classed as 'sulphide'. The 3-mm. stock is discharged from the hydraulic classifier into a two-compartment, 3-cell, Harz type of jig; the hutch products are similar to that of the Hancock. The middling from both sets of jigs is re-ground in Huntington mills or narrow-face high-speed rolls and then elevated to a series of spitzkasten; the overflow from the hydraulic classifier also passes to the spitzkasten; from here the feed passes to Overstrom and Wilfley tables. The table middling is re-ground in a Huntington mill and returned to the table feed.

At Mine Lamotte before any special attention was paid to the deposits of copper, nickel, and cobalt, the lead concentrate carried about 1.4% of these metals. The matte resulting from the smelting of the lead concentrate was calcined and fed into the furnace with another charge. The resulting matte was called second matte. This was again calcined and smelted in a small stack. Enough pig lead was recovered to pay for the handling of the matte. The resulting third matte ran from 8 to 10% Cu and 18 to 24% Ni and Co; this was barreled and shipped East. About six years ago the company began to mine ore richer in copper-nickel-cobalt ore. The mill then produced two kinds of concentrate: lead concentrate assaying about 68% Pb and 1.5 Cu, Ni, and Co, and a second called 'sulphide' which assayed 15% Pb, 2.5 Cu, and 3 NiCo. The ratio of cobalt to nickel is 1 to 1 in the ore. The 'sulphide' was roasted in a McDougall furnace and smelted in a small copula with roasted first matte from the lead-furnace. This second matte assayed about 25% Pb, 5 Cu, 8 Ni, and 5 Co. This matte was again roasted and smelted, some lead being extracted and the metallic content raised to 12% Cu and 30 NiCo. The matte was then dead roasted in hand calcines and ground to about 20 mesh, after which the matte was dissolved in earthenware digesting tubs with hydrochloric acid. The solution was then run into a tier of tanks, the iron precipitated by the addition of milk of lime, and the solution was filtered on a vacuum filter. The iron precipitate was returned to the blast-furnace. The solution was next pumped to another tier of tanks where the copper was precipitated by means of hydrogen sulphide gas. The gas was generated in three lead-lined gas generators of 150 cu. ft. capacity each. The iron sulphide was made by melting iron pyrite, iron borings, lathe turnings, etc., in a crucible furnace. Sulphuric acid was added to the generators with an acid pump. The spent acid from the generator was tapped into boiling tanks and the copperas crystallized out.

The copper sulphide was filtered and converted to an oxide in a hand calcining-furnace. The oxide was then dissolved in sulphuric acid and boiled to the proper degree Beaumé, and tapped into crystallizing tanks; the blue vitriol forming on a lead spider submerged in the tanks. The cobalt was next precipitated, using calcium hypo-chlorite as the precipitant. The precipitate was filtered, washed, then muffled and washed again. The finished oxide was then pulverized. The cobalt oxides averaged 68% cobalt. The nickel was next precipitated by adding milk of lime: the nickel hydrate was then washed and roasted to the black oxide of nickel, and either shipped in this form or reduced to shot nickel. This plant was shut down without fully demonstrating the practicability of the process.

Method of Specific Gravity Determination

Written for the MINING AND SCIENTIFIC PRESS
By A. C. DART

The following method for the determination of the specific gravity of solids is so simple as almost to require apologies for its presentation. However, having mentioned it to several to whom its application is of value and having found it to be generally unknown, I, to whom the idea is original, venture to publish it, together with records of a few tests showing its accuracy.

The apparatus required consists of an ordinary pulp-balance, weighing to the second or third decimal part of a gram, and a burette, or, preferably, a section of an old burette, 10 to 15 c.c. long, sealed at the lower end.

The method is as follows: weigh one or more pieces of the material to be tested, being sure that each is small enough to enter the burette; partly fill the burette with water and take its reading when as nearly in a vertical position as possible; place the weighed material in the burette, shake to free the adhering object from air-bubbles, and read again. The difference in the burette readings is the volume of the material, and the weight, in grams, divided by this volume, is the specific gravity. The temperature and purity of the water used do not affect the accuracy of the result.

For the determination of the specific gravity of middling, and other crushed products of concentration, a convenient modification of the method is to weigh about 10 gm. of the material and slowly add a part to the water in the burette until its reading has been increased by exactly one cubic centimetre, then weigh the portion remaining, and the difference in weight is the specific gravity.

In testing the accuracy of the method a few pieces of the following minerals and rocks were used: albite, apatite, chalcocite, fluorite, and obsidian. These were weighed, to the third place of decimals, in air and in water, dried, and the volume determined by burette readings. For obtaining the weights in water a small porcelain crucible was suspended by a loop and two wires of platinum in a beaker of distilled water which, in turn, was supported on a bridge over the left-hand balance-pan. Having balanced it with the crucible in water, the minerals were added and weighed in a continuous series, and the individual weights obtained by subtraction. For the purpose of better comparing the accuracy of the method the same pieces were determined by the Eimer & Amend 'universal hydrometer'. A tabulation of the determinations and results follows:

DETERMINATIONS—EXPERIMENTAL DATA.

Material.	Weight in air, gm.	Weight in water. gm.	Volume by loss in water, c.c.	Volume by burette, c.c.
Albite	2.619	1.603	1.016	0.99
Apatite	2.819	1.932	0.887	0.90
Chalcocite ..	2.234	1.840	0.394	0.40
Fluorite	1.769	1.214	0.555	0.56
Obsidian ...	1.614	0.931	0.683	0.69

RESULTS.

Material.	Specific gravity—By weight.	By burette.	By hydrometer.	According to Dana.
Albite	2.63	2.58	2.38	2.624
Apatite ...	3.13	3.18	3.03	3.091—3.215

STEEL FORMS FOR SHAFT LINING

Steel forms for shaft lining have been used in sinking the Brier Hill shaft in northern Michigan and are described in a paper by William Kelly before the Lake Superior Mining Institute. The shaft is vertical, 14 ft. diam., and has horizontal steel sets, 10 ft. 8 in. apart, to support the cage and skip guides, the ladder, and the pipes. The forms are ⅛-in. steel plate with bracing of angles to retain the circular shape. They are 5 ft. 4 in. high, and each circle is made in four segments. At two of the joints between segments are blocks to give space for collapsing the circle. Two rings of forms are used. After the excavation has been carried deep enough to allow three or four steel sets to be placed, supports are inserted in hitches in the rock wall and a platform built on them. A ring of forms is set on the platform, displacing boxes placed at intervals around the bottom, and the form filled with concrete. When the concrete has set the form is collapsed, hoisted, and hung from the lowest steel set of the completed shaft above. A steel set is then placed in pockets left in the top of the new concrete, the ring of forms lowered on it, the next ring placed and filled. The forms are raised when the concrete has set, another steel set placed, and the work thus continued. The closing ring of concrete between the new and older work above is placed through the holes left in the bottom of the concrete work by displacement boxes. A 10-ft. 8-in. ring can be concreted in an 8-hr. shift, and 12 hr. is sufficient for the concrete to set, so that it is possible to pour this height and place the steel in considerably less than two days. The excavation was facilitated by sinking a 6 by 8-ft. shaft first, and working upward from all the intersected levels of the old mine. The best record for enlarging and concreting was 69.3 ft. per month, made in two successive months. At that time eleven 10-hr. shifts were working per week. Each shift for excavating and concreting consisted of six men.

Aside from gold and silver, the chief minerals known to occur and mined in New Zealand are mercury (cinnabar), platinum, nickel, lead, tin, zinc, antimony, arsenic, manganese, chromium, osmium, iridium, tellurium, titanium, tungsten, and petroleum. The last-named is being worked by small companies in Taranaki and at Kotuku, in Westland, while tungsten is found as scheelite in considerable quantity in Otago. The available ore in the two veins being worked is estimated at 60,000 tons. It is being shipped to Europe, where it is used for the manufacture of high-grade steels. The export for 1907 totaled 137 tons, valued at £15,486.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Vacuum Filters at Pachuca

The Editor:

Sir—We beg to call your attention to the special correspondence from Mexico in your issue of March 12, and to correct several statements made therein. In mentioning the equipment ordered by the Palmilla Milling Co. at Parral for the 250-ton unit of the new plant your correspondent omitted the 180-leaf Butters filter plant. At the Dos Estrellas mine the Butters filter plant which is nearing completion, consists of 300 leaves and is calculated to handle 600 to 800 tons of dry slime daily and not 100 tons as stated. E. H. GARTHWAITE.

San Francisco, March 26.

High Priests and Promotion

The Editor:

Sir—Lately a lot of stress has been laid upon 'Professional Ethics', 'Qualified Mining Engineer', 'The M. E. Degree', and similar topics in several mining journals. There are also read addresses by the 'high priests' of the profession advising investors. I am not qualified as a writer, neither have I time nor inclination to enter an active discussion in this matter, yet I wish to protest against the injustice done to those who honestly and quietly work at the front developing new ground, blazing new trails, and emphatically to protest against the undue advertisement others receive through these articles. Our friends seem to favor a close corporation chosen by themselves to determine who is and is not qualified to report on or develop a mine. It seems to me time to call down these press bureau engineers who have been advertised to the top notch, and used to gull the public. The Newhouse mine at Cactus may be cited as an instance in point. It was reported on by an engineer sent out by the New York Stock Exchange. The stock went to $30, one dividend was paid; the rest is familiar history. Greenwater and Montgomery-Shoshone, vouched for by those who had berths at 71 Broadway, may also be cited. Nipissing and many others may be recalled to advantage. James Phillips, Jr., openly accuses some of these engineers of not only bad faith and misrepresentation, but actual neglect and dishonesty. They have not defended themselves. Perhaps they consider it beneath their dignity to defend their honor as mining engineers. Some of these gentlemen are advertised like Hammerstein's 'Song Birds'—so much per night. The churn-drill properties some are now vouching for may warrant a question or two. The game has been played so well that the copper stocks are selling at par, and some above. In the strict sense, Tom Walsh, Tom Kearns, W. A. Clark, Marcus Daly, W. S. Stratton, the Comstock pioneers, it would cover the history of mining to mention them all, including the South Africans, were neither capitalists nor mining engineers, yet they made good. I, for one, am sick and tired of, and have the utmost contempt for the engineer who allows himself to be advertised and exploited. A short time ago a prominent E. M. saw the powers that be, fixed the president for the merger—so the press agents told us—and as a result Amalgamated was put to $95 and Utah Copper to $66. Today they are $20 or more below these figures. The confiding public is paying interest on the stuff in the bag, and the Morganheims are in Europe buying works of art, while a new crop grows. I do not care to get in print, but this may be a subject of interest to many of your subscribers who do not dwell in the shadow of Wall street, Broad street, or lower Broadway. I believe $100 has been filched from the confiding public through these immaculate high priests, where one dollar has been lost by petty mining schemes and irresponsible promotions.

JOHN G. WORTH.

Reno, Nevada, March 28.

Bureau of Mines

The Editor:

Sir—It will probably interest your readers to know that the long-continued effort on the part of those concerned in the development of the mining industry of the United States to secure the establishment of a Bureau of Mines by the Government, is likely to prove successful in the near future. A very satisfactory bill has been passed by the House of Representatives and has been favorably reported by the Senate committee on mines. In the discussion which has arisen concerning the expediency of such a measure, certain objections have been stated which I should like to meet.

One of the arguments advanced in opposition to the establishment of the proposed Bureau is that it might duplicate the work of the Geological Survey, thus producing friction that might seriously affect the usefulness of one or both organizations. It is hard to see how such a duplication of work could possibly occur if the Bureau should be established under the provisions of the Huff bill now pending; for if this bill be adopted, the Geological Survey and the Bureau of Mines will be co-ordinate branches of the Government service under the direction of the Secretary of the Interior. Any man competent to fill this position may reasonably be counted upon to prevent any duplication of work, and to stimulate them to co-operate without friction, in their efforts to serve the public. If it were proposed to have the two organizations under separate cabinet officers, such an argument might have weight; but when two co-ordinate branches of one department are under the direction of its head, such a contingency seems to be likely only when that official is grossly incompetent and inefficient. In that case, any plan of organization would break down even if both duties were in charge of a single bureau. In order to show that the apprehended danger is not real, it is only necessary to call attention to the fact that the above arguments might be urged much more strongly against the present organization of the army and navy, which happen to be in charge of different cabinet officers. These organizations have been able to co-operate in the defense of our country very

efficiently, even though they are under the direction of separate secretaries. The work of the Geological Survey and that of the proposed Bureau of Mines, though bearing on the same general subject, are as different in their details as is the work of the army and of the navy of the United States. The Huff bill, while recognizing their separation, places them both under the direction of the same cabinet officer.

Another objection which I have seen urged is that "a scientific organization like the Geological Survey must of necessity have a highly trained staff; the same cannot be said of a Bureau of Mines." It is agreed that the first clause of the quotation is correct; but I do not know any reason why the members of the staff of a Bureau of Mines should not be equally highly trained specialists. I understand it is proposed that they should be. Men who have had the training of mining engineers ought to be at least as thoroughly trained and efficient for their work as are the assistants on the staff of the Geological Survey; and it is to be hoped that no others would be employed in the Bureau of Mines.

Another objection advanced is that it would be impossible to obtain the services of competent engineers for the salaries to be paid by the Bureau of Mines. This is really another form of the same argument. I should be much surprised if there were not many competent engineers in America who are as unselfishly devoted to the development of the mining resources of their country, and who take the same self-sacrificing interest in this great work, as has been taken by the members of the staff of the Geological Survey in theirs. I cannot bring myself to believe that the mining engineers of the United States are as a body, less efficient and more mercenary than the members of the staff of the Geological Survey. I feel sure that there are among them many men of the highest ability who would welcome such an opportunity to do genuine scientific work of a high order, which may lead to the wise conservation of the mineral resources of the country, to the saving of the lives of many miners, hundreds of whom are killed every year by avoidable accidents in the development of these resources—they would welcome an opportunity to do such work even at the sacrifice of large professional emoluments.

It has further been assumed that the new Bureau would be bound to come under political influence. The same argument was advanced when the establishment of the United States Geological Survey was proposed; but it has an honorable record, and has proved that it is possible for a Government organization to render efficient service independent of political influence. I see no reason why one bureau should be more subject to such influences than the other. The objectors should read the address of George S. Rice, at present employed by the Technological branch of the Geological Survey, printed in Bulletin No. 20 of the Mining & Metallurgical Society of America. He answers many objections which have been urged against the establishment of a Bureau of Mines.

I wish further to call attention to the fact that a number of interesting subjects of investigation aside from the main purpose of the United States Geological Survey, have grown up under its wing until it was found necessary, for convenient administration, to transfer them to some other agency. For examples, I might mention the ethnological investigations, which were for many years the hobby of the late J. W. Powell, long Director of the Geological Survey. Experience has shown that they could be best administered under other auspices and they were consequently transferred. The Reclamation Service was also for a long time part of the work of the Survey; and I have it from the present Director and from many of its members that the administration of this Service was found to be so different from that of the proper work of the Survey that it became necessary to transfer its administration to a separate organization. The point was that the engineering work of the Reclamation Service, dealing with large masses of materials and large groups of workingmen, required men whose training was quite different from that suited to the purely scientific work of the Survey. The same thing is true of the present Technological branch of the Geological Survey which has grown up under its charge. The investigations already undertaken have to deal with the economical use of fuels, coal, coke, oil, gas, and other mineral materials; with the safety of miners underground; with explosives, blasting, and fire-damp; all of which require men of engineering training and practical experience in mining. It is hard to find such men among those whose training has been that of the geologist only.

If a new Bureau be created as provided by the Huff bill, the Geological Survey and the Bureau of Mines will be of equal rank and each under competent supervision; they will both be under the direction of the Secretary of the Interior, and there ought to be no trouble in getting them to co-operate for the good of the country; and being separate, each will be more efficient. They could co-operate when it was necessary and work independently when it was not. Many of the bills first introduced in Congress were crude, and some would have seriously hampered the work of the Geological Survey. These were properly opposed by its friends of whom I am most emphatically one. The present bill is without these offensive provisions. I am sure that no mistake would be made in creating such a Bureau, but there are two things concerning which care should be exercised: (1) the work of the Bureau should be for the benefit of the whole public, not for private or personal interests. It should undertake only such investigations as are too large for an individual or a corporation to carry out, and should not concern itself with problems properly belonging to the initiative of the individual engineer. (2) It is of prime importance that if this Bureau be created it should have at its head a thoroughly trained mining engineer, whose character and attainments shall command the confidence of the entire country.

I suggest that to aid in the passage of the bill, all your readers who are in favor of this bill should put themselves on record with the Congressmen of their States, and show that the mining public is behind the measure.

SAMUEL B. CHRISTY.

Berkeley, California, March 24.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Tamping drill-holes in coal mines with drill dust, slack coal, or other inflammable material is forbidden in European coal-producing countries, it having been found that gas and coal-dust explosions are more likely to occur when such materials are used. The laws of Great Britain compel the use of clay or like substance for tamping. The material is delivered to the miner near the working place.

Edison's recently tested storage-battery car ran fifteen miles an hour loaded. The battery consists of 200 cells placed under the seats. The car can be run for 150 miles on one charge, which it takes four hours to complete. On an experimental track the car was run at a cost of 8 mills per mile, while that of the trolley car is about 5c. It is not expected that the cost will go over 2c. per mile for the storage-battery car, even under most unfavorable conditions. It costs about $6000, as against $10,000 for a trolley car.

Mining ranks second only to agriculture among the foundation industries of the country. It now contributes over $2,000,000,000 annually to the national wealth, as compared with $7,500,000,000 from agriculture; but it contributes 65% of the freight traffic of the country, as compared to 8½% from agriculture. Its manufactured products in 1907 amounted to a total of $4,318,598,661, and the wages paid to the men engaged in such manufacture amounted to $863,558,487, as against $735,101,760 paid to those engaged in agriculture.

Diamond-drill holes in loose ground may often be saved by cementing. For this purpose neat cement should be used mixed at the hole in small quantities just thin enough to pour into the hole. Put in enough to fill the hole about one foot and then tamp carefully with a blind bit turning the latter slowly until it begins to stick. The rods should then be promptly withdrawn and another lot of cement poured in. When the bad ground is passed the cement should be allowed to set twenty-four hours after which it can be drilled through as though it were hard rock.

Lime is added in cyanidation both to correct acidity and to induce settling of slime. The latter is accomplished by altering the surface tension of the solution. Best results are attained when the lime is slacked hour by hour as needed and mixed as the pulp goes from the plates or concentrates to the vats. If lime be fed into the battery the screens become clogged, the concentrating tables are coated and a much larger quantity is used. A good method is to shovel the lime into a box or half barrel, let it slack, transfer it to a water box where a small air jet keeps it in agitation and from which an overflow of water carries the milk of lime into the launders.

A comet's tail, according to W. H. Pickering, in the *Century*, is composed of gas, existing in a highly rarified condition. Little particles of electricity called corpuscles, or ions, are being constantly given off at enormous speed by the sun. Each meteorite in the comet's head is surrounded by its own rarified atmosphere. When one of these little ions strikes one of the molecules of gas in the comet's atmosphere, it carries it off with it to form the tail. The electrical charge makes the gas luminous, and it is by this light, and not by reflected sunlight, that the tail is made visible. A comet's tail, therefore, seems to be merely a very extended aurora.

Selenium is a non-metallic element, with characteristics similar to phosphorus, sulphur, and tellurium. It occurs in meteoric iron and in rare metals. Though universally distributed, selenium occurs only in small quantities. The chief interest in it is in the fact that light has a powerful influence on its capacity for conductivity of electricity. This fact was not discovered until as late as 1873, when Willoughby Smith communicated the fact to the Society of Telegraphic Engineers of London. Earl Ross substantiated Smith's statements by a series of spectroscopic experiments. These conclusively established the fact that light, and light alone, is the active agent in this peculiar change of conductivity.

Coal deposits on public lands are burning in a number of the Western States. There have been a number of coal beds on fire in northwestern Colorado coalfields, and a large part of the Yampa coalfields in Routt county, and also in the coalfields of Rio Blanca, Mesa, Garfield, and Pitkin counties. Coal beds are now burning on a large scale near Newcatle and at a number of other points in Colorado. On Grand Hogback mine fires are burning valuable beds of coal, and at Newcastle the coalfields contain an aggregate thickness of 108 ft. of coal, of which a single bed of coal now on fire ranges from 40 to 50 ft., this fire having started in a mine belonging to a private company and now extending to lands belonging to the Government.

Claimants for mineral ground when proceeding to patent should select some deputy mineral surveyor to make the survey and make arrangements for the work. The claimant then applies to the surveyor-general for the district in which the claim is situated, asking that an official order be issued directing the deputy to survey the claim. This application is accompanied by a certified copy of the location notice of the mine, and a certificate of deposit for $30 issued by a sub-treasurer of the United States depository authorized to accept such deposits. The applicant in making the deposit should give the name of the owner. The deposit is for the purpose of paying for work in the surveyor-general's office. Upon receipt of the application, the surveyor-general issues an order and forwards it to the deputy, who makes the survey in accordance with the instructions furnished by the department, and makes returns to the surveyor-general. In due time there is forwarded to the claimant a copy of the field notes of the surveyor, and two copies of the official plat. The claimant then prepares his application papers.

Special Correspondence

MEXICO

San Juan, Taviche.—Naica District, Chihuahua.—San Bernarbe, Zacatecas.—Real del Monte. — Elmore Process in Mexico.—El Oro District.

The Supreme Court of Mexico has just added a chapter to the litigation over the rich San Juan mine in the Taviche district of Oaxaca by affirming the decision of the Second Federal District Court, which recently returned the property to the possession of the San Juan Mining Co., an American concern. The company lost possession of the mine to Juan Baigts, the former Mexican owner, through the action of an Oaxaca court in January, 1908, and on November 19, last, the case was reopened by an appeal to the Federal District Court, it being alleged that the company was never properly served, that many other errors were made, and that the judgment was secured by default. While there is nothing in the decision of the Supreme Court that prevents Baigts from again instituting proceedings for the possession of the mine, it shows that the highest court of the Republic will not allow individuals or corporations to be deprived of property without a full hearing, and is accordingly gratifying to foreigners and foreign companies interested in the mining industry in Mexico.

It is announced from the headquarters of the Compañia Minera de Naica at San Pedro, Coahuila, that an option on the company's San Pedro and other mines in the Naica district of Chihuahua has been given American interests. The price is stated to be ₱6,000,000, with a deposit of ₱50,000, which will be forfeited if the purchase is not made. The Naica is the concern that has plans for a smelter to cost ₱1,000,000 at Concho, a station on the main line of the National Railways. The company was organized with a capital of ₱30,000, divided into 100 shares of a par value of ₱300 each, and the option price represents an increase to ₱60,000. This Mexican concern has had an extraordinary record, and is one of the big dividend payers of the Republic. The building of the Terrazas-Madera link of the Mexico Northwestern railroad is resulting in some activity in the old Guaynopa district, which will be benefited by the new line. The Tres Amigos Gold Mining Co. has resumed work and is doing extensive development. Luis Terrazas, Jr., Charles Seawell, and J. W. Clayton, all of Chihuahua, recently secured a concession for a smelter in the Guaynopa district, and may dispose of it to foreign interests. Opportunities for hydro-electric installation exist in that section of Chihuahua. The Candelaria Mining Co., operating the Candelaria, Congreso, and other mines at San Pedro, in northern Chihuahua, is installing a concentrating plant. Shipments of ore to the El Paso smelter now range from 100 to 150 tons per day. The company has one of the largest mine pumping plants on the continent. The Rio Plata Mining Co. has just paid its second quarterly dividend. The rate was 2%, an increase of 0.5% over the first dividend.

The San Bernabé mine in the Zacatecas district of Zacatecas, the oldest mine in that section of Mexico, has been taken under a working option by a company subsidiary to the British-Mexican Development Co., of London. The mine will be unwatered, new development work commenced, and an experimental reduction-plant erected. The San Bernabé was opened in 1584, and it has a recorded production of many millions. The San Carlos Gold Mines, Ltd., of London, which was recently reorganized and new capital provided for operations, will resume milling at its properties in the Mezquital del Oro district of Zacatecas. The old 50-stamp mill and cyanide plant are being overhauled, and it is expected to handle from 4000 to 4500 tons per month.

The Real del Monte y Pachuca Co. reports an output of 12 tons of silver bullion in the month of February. The bullion production of the Pachuca district is increasing steadily, and is now close to 30 tons per month. The district is at present suffering from a scarcity of power, and little relief can be expected until the transmission line of the Mexican Light & Power Co. for the delivery of Necaxa power is completed, in June or July. New equipment recently installed at the San Francisco custom reduction works will be soon in commission. It consists of 20 stamps, 8 concentrators, 2 tube-mills, 3 Pachuca tans, and a Moore filter. Preparations are being made for further additions. Rich ore has been found in the lowest workings of the Sorpresa mine of the San Rafael y Anexas Co. The company continues to pay big dividends regularly. In the Argentina mine at El Chico, Hidalgo, ore assaying as high as 1½ kg. silver and 300 gm. gold has been opened. H. T. Oliver is in charge of the property for the Argentina Mining Co. A. E. Lafrancoso, a mining engineer representing English capital, has bought the Union mine west of Real del Monte. It adjoins the old Cruz de Todos Santos property.

The mines and small reduction plant of the Beryl Gold Mining Co., of San Diego, in the San Andrés district of Lower California, are under option to English interests, and the mines are being examined. The ore in sight is estimated at 75,000 tons. Patrick Burns, the wealthy British Columbian packer, is investing in copper properties in Lower California. The mines purchased are said to include those of the Julius Caesar Copper Mining Co., which suspended operation some time ago. The Peninsula Onyx Co., operating in Lower California, sold $137,000 worth of onyx in the United States last year. It is stated that this year's sales will exceed that amount.

The Magistral-Ameca Copper Co., of the Ameca district of Jalisco, will be the first in Mexico to use the Elmore flotation process in the treatment of copper ores. The first Elmore plant in Mexico was recently installed in the Parral district of Chihuahua by the American Zinc Extraction Co., for the treatment of zinc ores. Jigs and tables are expected to save 60% of the mineral in the Magistral ores, and working tests have shown a total extraction of 92% by the Elmore process. Delays in the arrival of machinery will make it impossible to have the 100-ton plant ready for operation before May 1. The Chapala Hydro-Electric & Irrigation Co. will extend its Etzatlán transmission line into the Ameca district of Jalisco, and supply mining concerns there.

Official figures show that the four big concerns of the El Oro district of the State of Mexico, the Dos Estrellas, El Oro Mining & Railway Co., Esperanza & Mexico Mines of El Oro, milled 922,766 tons of ore in 1909 and spent ₱749,934 in permanent improvements. The total production of the four concerns is given at ₱20,242,351, and the profits at ₱9,062,583. The profits were divided as follows: Dos Estrellas, ₱4,227,235; El Oro Mining & Railway, ₱1,828,760; Esperanza, ₱1,515,828; Mexico Mines, ₱1,490,760.

KALGOORLIE, WESTERN AUSTRALIA

Development and Production in January. — Perseverance Mill.

The gold yield of this State in January was valued at $2,632,320, being a decrease of $101,900 with the same period of 1909; but the temporary stoppage of the Perseverance, and the low returns from the Associated and Associated Northern account for this drop. The lode in the Great Boulder at 2500 ft. has been driven on for 700 ft. averaging $15 per ton. The Main shaft is down 2660 ft., and Edwards' 2600 ft. Sinking is proceeding, and the mine at the above depth is very satisfactory. The Kalgurli has been looking a little better of late, and at 1650 ft. the crosscut in the south drift shows 5 ft. of ore worth $14, and a farther 6 ft. worth $4. The Associated publishes its ore reserves, as 465,525 tons, worth $7.50 per ton, and the Golden Horseshoe, 1,078,638 tons at $11 per ton. The former has a lot of low-grade ore of late, and returns are low. The mill may be increased by two No. 8 Krupp mills, and a couple of Edwards' duplex roasters, two of the latter being at work roasting over 80 tons daily each. The Horseshoe is increasing its mill to equal 200 head of heavy stamps, and also installing a low-pressure turbo-generator of some 750-kw. capacity. The Perseverance management is hurrying with its new milling department to replace that portion burnt. The eight No. 8 Krupp mills are now

arriving. The foundations for these and the ore-bins are well under way, and the place presents a busy scene. The mill has only treated 19,000 tons monthly so far, but an increase may be expected. Ball-mills require some careful attention on these ores, to get the maximum efficiency. The January returns from the large producers were as below:

Name.	Tonnage.	Value.	Profit.	Dividend.
Associated	11,616	$ 78,000	$ 4,200	.....
Associated North'n Blk.	3,132	21,000	2,000	$87,000
Chaffers	4,143	27,000	1,000	.....
Golden Horseshoe	24,892	139,000c	13,000	375,000
Golden Ridge	2,219	28,000	14,000	.....
Gt. Boulder Proprietary	17,862	250,000	136,000	.....
Great Fingall	10,339	75,000	10,000	.....
Hainault	5,894	40,000	7,500	.....
Ivanhoe	19,642	205,000	100,000	250,000
Kalgurli	10,810	138,000	76,000	185,000
Lake View Consols	11,347	77,000	12,000	.....
Oroyo-Brownhill	22,371a	31,000	14,000	.....

South Kalgurli	9,040	62,000	14,000	.....

a. Only retreatment of old dumps by the vacuum process.
b. The initial return from the new amalgamation.
c. A drop of $110,000.

TORONTO, CANADA

Cobalt Dividends.— Power. — Stock Market. — Ore-Stealing. — Mining Labors and Federal Jurisdiction.

Cobalt has certainly made a good showing for the first quarter of the year in the matter of dividends. So far eight companies have declared $2,277,961. This is additional to the profits of close corporations like the O'Brien and Drummond, and the payments in royalties to the Provincial Government. The largest payments are Nipissing, $900,000; Crown Reserve, $530,644; La Rose, $300,000; and Kerr Lake, $300,000. The highest rate paid is by Crown Reserve, being 12% dividend with an 18% bonus. The Haileybury Silver Co. figures in the list with a payment of $25,000, being 50% on its small capitalization, but the money comes not from ore production but from the sale of one of their properties. The Coniagas has passed its dividend, owing to the cost of putting the smelter at Thorold, Ontario, on a sound economical basis. Recently about seven tons of silver was shipped to England.

Rapid progress is being made in the installation of electric power at Cobalt. The sub-stations in connection with the Mines Power Co. are receiving the full load of 44,000 volts over the transmission lines from the Matabitchowan river, and plants and mills aggregating 1775 hp. are now connected with the system. These include the Nova Scotia mill, Silver Cliff, O'Brien, Northern Customs concentrator, McKinley-Darragh, and Bailey.

The stock market continues in the main quiet, with operations limited, owing to lack of public interest, but improved mining conditions are having some effect upon the lower priced issues, which are gradually advancing. The most noticeable feature has been the heavy demand for Cobalt Lake followed by a steady rise in price consequent upon the decision of the directors to reduce the capitalization from $5,000,000 to $3,500,000 by buying in and canceling stock. The long-pending action of the Florence Mining Co. against the Cobalt Lake Co., claiming the property on the ground of previous discovery, has been finally settled by the decision of the Imperial Privy Council, to which an appeal was taken, confirming the judgment of the Ontario courts dismissing the action. The main issue was whether the Ontario Legislature had power by special legislation to confirm a title and stay litigation proceedings. This much disputed question is now definitely settled in the affirmative, and the decision will affect more important interests than those involved in this particular case, as the same question has since arisen in connection with the Provincial Government's hydro-electric scheme, several lawsuits having been stayed by the fiat of the legislation.

This week several cases of ore-stealing arising out of the discovery some months since of a wholesale system of thievery by which the Cobalt mines have been robbed of large amounts, were brought to trial in Toronto. The results so far have not been such as to encourage the hope that the existing machinery of legislation is sufficient to check the practice. Three prisoners were put on trial charged with selling ore without the authority of the mine-owner. The defence set up was that the prisoners did not sell the ore, but the silver, the transaction not being completed until the metal was refined, and that the act did not touch the sale of 'silver'. In two cases the juries disagreed, the third, a verdict of 'guilty' was returned against George Barber. The prisoner's counsel asked for the submission of a stated case to the High Court for the decision of the point raised. This was granted and the remainder of the cases traversed to the next court.

The unsatisfactory and confusing condition of the mining laws of Canada relating to those districts that remain under Federal control, as distinct from the jurisdiction of the Provinces, has long demanded attention. The matter was brought to the notice of the Dominion Government this week, when a strong deputation from the Canadian Mining Institute waited on Sir Wilfrid Laurier, the Premier, and Hon. William Templeman, Minister of Mines at Ottawa. Among the changes sought was the placing of the issuing of mining titles, and the administration of mining laws in the hands of the Department of Mines, and the consolidation of the mining laws. The Premier intimated that these recommendations would be carried into effect. The work of consolidating the mining laws has been entrusted to a sub-committee of the House of Commons Committee on Mines, who in drafting the measure will consult with representative mining men. The bill will be submitted to Parliament next session.

WASHINGTON

Pinchot-Ballinger Inquiry.—Alaskan Coal and Oil Lands.—Conservation Legislation.—Bureau of Mines.

Among recent witnesses before the joint committee investigating the Pinchot-Ballinger controversy were Stephen D. Birch, managing director of the Morgan-Guggenheim Syndicate of Alaska, and John N. Steele, its attorney. Mr. Birch said he first saw Clarence Cunningham in connection with his Alaskan claims at Seattle early in April 1907. In August of the same year, the Guggenheims notified Mr. Cunningham that they had been advised by counsel not to purchase the claims in their incompleted state, and requested that the patents be hurried. He replied that the issuance of patents was a matter that rested with the convenience of the Government. Mr. Brandeis read a telegram from Daniel Guggenheim to Clarence Cunningham dated December 7, 1907, "finally accepting the proposition made in the memorandum agreement of July 20" by Cunningham, Moore, and Campbell on behalf of themselves and their associates. A letter from Mr. Cunningham acknowledging receipt of the telegram also was put in evidence. Mr. Brandeis was about to question Mr. Birch concerning the report of the expert sent by the Guggenheims to examine the Cunningham coal claims when Mr. Steele protested against making the report public, it being a private matter. He was willing to let the committee have the report in confidence, and this was agreed to. Mr. Birch testified that the Guggenheims had projected a railroad from Katalla to the coal lands. Later they changed their plans to build from Cordova to the copper fields. When Mr. Cunningham heard of this change early in 1908, he told Mr. Birch that the agreement had been violated, that it was no longer binding, and would not be lived up to. The witness said he did not consider the change of plans a violation of the agreement, for, as a matter of fact, the Cunningham claimants had done nothing on their side of the contract.

The nine so-called conservation bills, which contemplate a complete overhauling of the land laws of the country, are still resting on the calendar of the Senate. They are reached from day to day, but are always put over on the ground that Mr. Nelson of Minnesota, in charge of the bills, is busy with the Pinchot-Ballinger inquiry Many Sena-

tors are beginning to question whether anything will be done with these measures during this term of Congress. Meanwhile individual members continue to introduce additional bills. Herbert Parsons, Representative from New York, has added to the general interest by introducing a joint resolution calling upon the Secretary of the Interior to inform Congress whether he has any reports on the public land laws of foreign countries relating to the disposal of such lands and the deposits therein, by lease rather than by grant, and by disposal of the surface as distinguished from the deposits, and the development and practical workings of such laws. James W. Good, Representative from Cedar Rapids, Iowa, has introduced a bill providing for leasing the coal and oil lands of Alaska to the persons agreeing to pay the largest amount of royalty. Sylvester C. Smith, Representative from Bakersfield, California, has a bill proposing to classify all the public lands. The measure provides that such lands, when classified, shall be disposed of in accordance with existing laws. A proviso states that where lands are classified as containing mineral substances the surface may also be given separate classification according to its chief value and proper use. He also would have the general mining laws of the United States applicable to all lands containing valuable mineral deposits, irrespective of the classification under this act, upon proof of the existence of such valuable minerals therein. That many of the functions of conservation popularly ascribed to the Federal Government belong to the States is the belief of many members of Congress. Wesley L. Jones, Senator from Washington, evidently shares such a belief, for he has introduced a bill providing that all sites for use in connection with the development of water-power shall not be subject to entry or disposition under any of the public land laws of the United States, but at the request of the States shall be turned over to them; provided the laws of such State fully prevent power monopoly. The States, under these circumstances, must never alienate the fee simple title to the land so conveyed.

The bill to create a Bureau of Mines in the Department of the Interior got a rude jolt in the Senate several days ago. The bill was on the calendar under Rule No. 8, which permits it to be called every time it is reached, providing it goes over without prejudice. When the bill was announced, Eugene Hale, Senator from Maine, made a motion that it go to Rule No. 9, which was agreed to. The calendar under this rule is rarely, if ever, reached, and in order to get a bill on it up for hearing, it is necessary to make a motion at the proper time and have that motion passed by a majority vote. Charles Dick, Senator from Ohio, and chairman of the committee on mines and mining, who has charge of the bill, was out of the chamber when the measure was called up.

BUTTE, MONTANA

Production for April. — Below Normal. — Tuolumne Producing.

The Butte district produced 23,963,860 lb. of copper in March from 360,995 tons of ore, which is still about 5,000,000 lb. below the normal production. The Tuolumne, included in the miscellaneous, is estimated to have produced 1,000,000 lb. The production by the different companies in tons of ore and pounds of copper in March were as follows:

Companies.	Tons of Ore.	Pounds of Copper.
Boston & Montana	96,100	6,823,100
Anaconda	106,950	6,630,900
Butte & Boston	10,850	672,700
Washoe	7,750	472,750
Parrot	3,875	240,250
Trenton	9,300	576,600
North Butte	35,650	2,317,250
Butte Coalition	48,050	3,123,250
Original	18,600	1,190,400
East Butte	8,370	569,160
Miscellaneous	15,500	1,317,500
Totals	360,995	23,963,860

BAKERSFIELD, CALIFORNIA

San Joaquin Valley Oil Fields. — Great Activity Everywhere. — Enomous Gushers and Much New Territory.

California is now in the midst of its greatest and healthiest oil boom. After a quiet period of nearly ten years the industry has re-awakened and oil is now by far California's leading mineral product. Veterans of the boom of ten years ago, who, when oil dropped to 15c. per bbl., abandoned it for the metal mine or the farm, are again to be seen in crowds on the streets of Bakersfield and Coalinga. With them are returning the parasites, those unscrupulous promoters who floated thousands of worthless companies, and only recently have done much to blacken the name of Nevada. The Coalinga district leads by a safe margin, and owing to the immense acreage of demonstrated territory, seems destined to continue to do so. The latest development of note is the completion of the Coalinga Mohawk well at about 4000 ft. This is upon the crest of a large broad anticline, that crosses the East Side field, and is nearly a mile out from any other producing well. The production has been above 2000 bbl. per day of 31° oil. This is much lighter than any oil produced in the district except that from those remarkable wells in the old Oil City pool on Sec. 20. Two new pipe-lines to tide-water have just been completed, and in 1910 Coalinga should show a greatly increased production. The Kern River still continues to produce oil at a rate of nearly 40,000 bbl. per day. There is nothing spectacular about the bringing in of a well there as they come in small. However, the wells are shallow and the drilling easy so the oil produced represents a good return on the investment. A well being drilled by the Santa Fe, about two miles south of the last producing wells, has reached a depth of more than 2400 ft. As yet they have had no great encouragement. The Midway-Sunset-McKittrick district has in the last few months, been the scene of the most phenomenal developments in the history of California's oil industry. Closely following each other extraordinarily large wells were brought in by the following companies: Santa Fe, St. Lawrence, Ethel D., K. H. O., Standard, Mays, and Lakeview. The latter is at Sunset, and is the greatest well ever brought in California, and has been gushing at a 30,000-bbl. rate since March 15. The oil flows in a black column nearly 300 ft., and much is undoubtedly lost by volatilization. The Mays well is located in the extreme northern portion of the proved Midway field, and is about 15 miles from the Lakeview. It gushes occasionally at a 50,000-bbl. rate, but has not as yet flowed continuously for any great length of time. The Standard gusher has been producing since the first of the year and is still delivering 6000 to 7000 bbl. per day to the pipe-lines. Naturally, these developments have caused unusual activity in the region and the Midway boom has no parallel. To add to the interest a wildcat well, in the Buena Vista hills, drilled by the Honoluiu Oil Co., came in late in January. Though not yet completed, it makes over 100 bbl. per day of 28° oil. There is considerable unpatented land in the vicinity and the title to nearly all vacant sections is claimed by several locators. Hundreds of horses and mules are employed, day and night, hauling timber and supplies to the outlying hills, and the bustle and activity of Taft and Maricopa compare favorably with the Nevada mining camps in their boom days. The McKittrick field is still producing at its regular rate. The field is very narrow and does not contain more than 800 acres of demonstrated territory. Some of this territory has a great thickness of oil sand and has been very productive. The old Shamrock No. 3, which began flowing in 1901 at a 1500-bbl. rate, still flows more than 300 bbl. per day, and is one of the most remarkable California wells ever brought in. Late in 1909 the Nacirema Oil Co. brought in a well on the lower row of hills to the northeast of McKittrick. This well produces about 30 bbl. of tar-like oil, and is of little value for itself, but it has caused some activity in that vicinity which may uncover something of importance.

From a few miles north of McKittrick, to several miles southeast of Sunset, a distance of more than 40 miles, there is hardly a section of land upon which there is not a new derrick standing.

NEW YORK

Collapse of the Granby. — British Columbia Copper. — Phelps-Dodge Report.—Bank Finds Itself Richer.—North Butte. — Porcupine.

Not since the first move was made to work up interest in coppers has public enthusiasm received such a set-back as has come from the collapse in Granby. The relations of the Granby to Great Northern Railway, and the fact that J. J. Hill has always been supposed to be one of the largest stockholders have always given the property high standing. Many investors, who, as a rule, shunned mining securities, made an exception of Granby. No market rigging accompanied the discovery of the decline in ore reserves; all hands were taken by surprise. In view of the superlatives which have been lavished on Granby and the awakening following Otto Sussman's report, estimates of 'developed' ore, with figures as to tonnage and the profit to be derived therefrom are likely to be heavily discounted for some time. Such estimates and figures have been used liberally in connection with 'porphyry coppers'. One of the leading authorities of the copper world, a geologist whose name must be withheld, recently characterized the situation as "criminal, in obtaining money under false pretense." It is characteristic that encouragement is found by some in the plight of Granby. They argue that there may be others in like condition, and, therefore, the low-grade steam-shovel coppers may not be dangerous as regards over-production as contended. Nevertheless the coppers have lost favor and the merger, so recently an absorbing topic of interest is largely disregarded. The second large producer of the Boundary camp, the British Columbia Copper Co., has abandoned none of its plans for an increased production by reason of the Granby episode. Work has been started already on enlargement of two of the three furnaces, and negotiations are under way to induce the Canadian Pacific road to build a seven mile spur to connect the Lone Star mine with the Wellington group; failing this, an aerial tramway will be constructed.

The 1909 report of the Phelps, Dodge & Co., Inc., shows a production for the year of 130,204,764 lb., as against 113,870,914 for 1908. While the dividends paid by the company during the year, 10.8%, leave no question as to profit earning, it is a little disappointing that the average selling price of the copper and the cost price per pound are not stated. About 1000 acres of ground, the property of the Burro Mountain Copper Mines, with some 2,000,000 tons of ore proved, was acquired during the year, and is to be held in reserve.

Shares of the Phoenix National Bank recently scored an advance without apparent cause. After some diligent inquiry the fact was reluctantly disclosed that some years ago the bank acquired in settlement of a claim, a block of Copper Queen stock, with other collateral. It was inventoried at a nominal figure of $1, and, by some strange oversight, was exchanged into Phelps, Dodge & Co., Inc., without being placed among the assets of the bank at any increased figure. Only recently the bank realized that an asset of $500,000 was not being counted in its balance sheet. The discovery results in an addition of about $50 to the book value of the bank shares and as the copper stock will probably be sold, there will be a melon. A member of the Boston Stock Exchange is soliciting proxies in behalf of the minority stockholders of the North Butte. It is interesting to note in this connection that there is sent with the request for proxy, a quotation from a letter of Thomas F. Cole, dated December 27, 1909, as follows: "A great deal of misleading information has recently been given out by the newspapers to the effect that we do not own the apex of the Jessie vein. We do own it, and the neighboring company, which is claiming the ore in this vein has simply a five-eighths interest in a small triangular piece of land through which the vein passes. We own it on both sides of this small strip." The Boston letter quotes Mr. Cole's statement as "representing the true condition of the mine today." It is quite evident that the 'neighboring company' referred to is the Tuolumne, and the statement so quoted in the letter is particularly interesting as being the first made officially, and given out publicly as to the position of the North Butte in regard to the apex question. It is equally evident that the fact has been overlooked that the Tuolumne has since the date mentioned been shipping each day from 100 to 300 tons of the richest ore in Butte from the ore-bodies in question, and will have a production in March of 1,000,000 lb. copper, at by far the lowest cost of any of the mines in Butte. Since this is done without protest from the North Butte, it follows that the North Butte has abandoned its position wholly. The questions involved are accepted in Butte without argument as being the real reason for the Anaconda merger not including the North Butte. The controlling interests in the South Side M. Co., which ground the South Quincy was to take over, have postponed action on the proposed sale to the new company and are contemplating doing some drilling. The ground lies to the south of the Hancock, and is believed to carry the extension of the Hancock and Pewabic lodes. Elbert H. Gary and William E. Corey are interested in a company headed by Ambrose Monell, of the International Nickel company, which has purchased the Wilson 'dome' claim in the Porcupine goldfield, and is preparing for vigorous work during the summer.

LONDON

Mysore and Nundydroog Report a good Year.

The progress at the gold mines belonging to the John Taylor & Sons' group in Mysore, India, is always watched with keen interest by those who wish for a speculative investment that depends for its risk solely on the fortunes of the ore deposit itself and not on the manipulation of the market by those behind the scenes. The longevity of these mines is remarkable, and at the present time, after a 30-year life, the Mysore and the Nundydroog are both in better position than ever before. Naturally there is not as much ore as at the beginning, but it must be remembered that at no time during the life of the mines could this great extraction have been predicted. In fact at the beginning of operations in 1882, the shareholders were more than half inclined to give up the venture in despair, and if it had not been for John Taylor's persistence the whole district would have been abandoned. The Mysore will always be quoted as an example of the advantages of perseverance in mining. Since the commencement of production in 1884 the total output of gold has been £11,680,522, and the dividends distributed have amounted to £5,935,094. At the present time the ore reserve amounts to over a million tons, an increase of 30,000 tons during the year, and the vein is maintaining its width and value at the deepest workings, one of which is down 3900 ft. on the dip, another 4200 or about 2700 vertically. Consequently, in spite of the age of the mine and the depth of the workings, the outlook is uncommonly good. During the year 1909 the 210 stamps were in full operation and crushed 234,500 tons of ore, yielding by amalgamation 202,359 oz. of bullion. The cyanide plant treated 190,388 tons of tailing, and produced 25,890 oz. bullion. The total value of the gold was £894,834. After paying royalty and adding other small receipts, the total income for the year was £854,959. The expenses at the mine and in London were £390,855, leaving a profit of £464,103. Out of this £350,750 has been distributed as dividend, being at the rate of 115% on the nominal capital. In addition £20,000 was placed as the nucleus of a reserve fund, £25,230 was allocated for income tax, £50,000 was allowed for expenditure on capital account and depreciation, and £19,950 was spent on exploration at the Dharwar goldfield. The new shaft known as Edgar's is down 2600 ft. vertically and the equipment is nearly complete. Connection has been made between this shaft and the workings in the main part of the mine at the 3226-ft. level, and the ventilation of the mine has been greatly improved. The output of gold for 1909 was the highest on record, but the rate of dividend was rather less than during the years 1898-1907. This is accounted for not by an increase in cost, as might be supposed by a casual observer, but by the fact that until two years ago extensions of plant and additional shaft-sinking were paid for out of new capital specially issued for the purpose.

General Mining News

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—Since the flooding of the lower levels of the Tombstone Consolidated on June 1, 1909, the water has been lowered to 125 ft. beneath the 800-ft. level. This has been accomplished by the installation of two Prescott station pumps on the 800-ft. level. The new compressor supplied only sufficient air to operate two sinking pumps, and for this reason the water has not been lowered as quickly as at first expected. Very little mining is being done at present. About 15 miners are being employed following contacts between the quartzite and limestone on the 700-ft. level, and a few men are engaged in sinking a single compartment shaft on the Northwest claim.

Tombstone, April 2.

The work of widening the main drifts from the Holbrook and Czar shafts of the Copper Queen Consolidated Co., at Bisbee, and raising the chutes to make room for the new motors will be completed about the middle of the month. The raising of the Holbrook shaft from the Spray drift has been started and it will be in working order May 1. The Czar cut-off has been finished and cross-cuts from this have opened from 15 to 30 ft. of commercial ore.——At the Superior & Pittsburg the Briggs shaft is down 1200 ft. and a station is being cut at that level and a pump set in position. Sinking is continued in the shaft and a drift has been started to connect with the Junction and Hoatson shafts. The drift on the 1500-ft. level of the Junction opened a body of sulphide ore.——The Shattuck-Arizona is hoisting 300 mine cars of ore per day from the 500 and 600-ft. levels. Much of this is high-grade material assaying over 20% copper. The stopes are now being timbered by stulls only instead of using square sets.——The adit at the Virtue property at Paradise is now in 700 ft., the face being in a hard gray limestone. A stove and suction pipe is to be installed to improve the ventilation and later the company may install a compressor and machine-drills. It is expected that the contact between the limestone and porphyry will be cut within the next 400 ft.——The Whitetail Mining & Milling Co. has been organized to take over the Doran & Gallagher property and expects to increase the force at the mine in a short time.——The 80-stamp mill of the Commonwealth Mining Co., at Courtland, was recently destroyed by fire. The mill had been remodeled a short time ago, and fitted with tube-mills and filter plant.

GILA COUNTY.

(Special Correspondence).—A new corporation, the Great Eastern Development Co., capitalized at $500,000, divided into 50,000 shares at $10 par, has purchased the property of the Arizona-Colorado Copper Belt and Gold Mining & Milling Co. for approximately $900,000. According to the terms of the option held by E. M. White, formerly manager of the Warrior Copper Co., who is the organizer of the Great Eastern company, $35,000 cash is to be paid in one month, and a cash balance of $225,000 and $650,000 worth of stock in a mining company to be formed later will be due at the end of three years. The Arizona-Colorado property consists of about 400 acres of mineral land, three miles north of Globe. The present workings on the land consist of numerous pits and adits and a 900-ft. shaft with eighth and ninth levels established. E. M. White is manager of the new company.——The Cactus Copper Co. has just placed a Starr churn-drill on its property. W. H. Hamilton is superintendent.——The McGaw shaft of the Superior & Boston Copper company is being equipped with the water and steam columns for the pump just installed at the sixth level. The east and west drifts on the Black Oxide vein on the 400-ft. level of the Gardner shaft of the Superior & Boston mine are opening what is apparently a large body of ore averaging about 8% copper, and having a high iron content making good fluxing material.——The sinking of a third churn-drill hole has just been commenced on the Eureka group of claims belonging to the Cordova Copper Co.——The sinking of the Williams shaft on the property of the National Mining Exploration company has been temporarily discontinued at a depth of 680 ft., while a station is being cut at a distance of 660 ft. from the surface preparatory to cross-cutting. The material in the bottom of the shaft is red shale containing considerable hematite. A 200-hp. boiler will soon be added to the surface equipment.——The vertical shaft on the Live Oak property has been sunk from the 329-ft. mark to a depth of 350 ft. since work was resumed there about a week ago.——The Warrior mine is producing over 100 tons per day of chrysocolla ore averaging about 9.5% copper.

Globe, April 1.

YAVAPAI COUNTY.

The Commercial Mining Co. is installing a new hoist at its property in the Copper Basin district. A. J. Pickerell is superintendent.——The new 10-stamp mill at the Crosby-Neiman mine, 16 miles northwest of Hillside, has been started and is now running satisfactorly. There are 30 men employed in the mine, which is down 260 ft. J. H. Boyd is manager.——The adit of the Big Pine Mining Co., operating in the Hassayampa district, opened 3 ft. of ore when in 175 ft. A drift has been started on the ore which was cut at a vertical depth of 120 ft.——A 2½-ft. vein of $60 ore has been opened in the Devonshire mine.——Sinking has been resumed at the 500-ft. level of the Leghorn mine in the Cherry Creek district. A new Lane mill has been installed in the company's plant and a better saving is being effected.

CALIFORNIA.

CALAVERAS COUNTY.

The Newman mine, at West Point, is soon to resume operations.——A new mill is to be erected at the Little Daisy mine in the Mountain Ranch district this summer.——Operations are to be resumed at the 400 mine this month.——The Summit mine, on Esperanza creek, has been bonded to San Francisco parties.——The Ball Mountain Mining Co. has unwatered its shaft, now down 473 ft., and will probably break through the lava cap into the bedrock in a short time.——A pocket estimated to contain approximately $100,000, has been opened in the Crystal mine at Angels Camp. James V. Coleman is the owner.——Good ore has been opened by the drift at the Smythe-Ryland mine.——The work of removing 40 stamps from the 100-stamp Stickle mill to the Gold Cliff mine has been commenced by the Utica company.——It is reported that work is to be resumed at the Lightner mine at an early date.

KERN COUNTY.

There is another lot of ore on the dump of the Pearl Wedge property for shipment to the mill. This will be the fourth lot sent out recently and is expected to contain about $3000 worth of bullion. The shaft is now down 150 ft.——Eleven tons from the Merced mine in the Stringer district milled $2500. The ore was mined at the 100-ft. level.

NEVADA COUNTY.

The drift at the Red Ledge property, at Washington, is opening some good ore and it is probable that the owners will erect a 5-stamp mill this spring.——The Cassidy Consolidated Gold Mining Co. is arranging to install new machinery at its recently acquired claims in the Grass Valley district.——The El Oro Mining Co., which has been operating the Marcotte claim in the Washington district for some time, is planning the consolidation of a number of claims in that vicinity, including the Marcotte, Starr, Ethel, and Baltic groups. There is a mill on the Marcotte and one on the Ethel groups, and it is proposed to open the properties by a long adit near Canyon creek.

PLACER COUNTY.

A portion of the equipment for the new dredge at Cash Rock is at the Auburn depot and will soon be hauled to a dredge which is rapidly being completed.——The Lee Brothers have crushed the ore stored on the dump and shipped the bullion to the mint. It is their intention to install concentrating tables in the plant as the ore contains considerable rich sulphide.——The company operating the Rawhide property is laying the second pipe-line to the mill.——The Spring Garden company is to let a contract to drive a 3000-

ft. bedrock adit.——Pay gravel has been uncovered in the Big Gun property at Michigan Bluff.——J. B. Hobson has granted a lease on the channel under the townsite to W. N. Bissett and an adit has been started to open the gravel. The channel has been worked close to the western edge of the town and has paid well.——Work has been started on the Humbug property, on the American river, after an idleness of eight years. Harry W. Morris is manager.

SIERRA COUNTY.

The Haskell Peak Mining Co. is running an 800-ft. bedrock adit at its property on the border of Sierra and Plumas counties. A prospect shaft has been sunk 190 ft. to bedrock opening 8 ft. of gravel.——The shoot recently cut at the Sierra Buttes mine, near Downieville, contains high-grade ore. A 200-ft. drift has been started that will open the ore the length of the shoot.——A recent test on the concentrate from the Standard mine gave a result of $11 per pound.

TRINITY COUNTY.

Hydraulic operations have been started at the Nash Deep Gravel mine, on Coffee creek, and a successful run is anticipated.——It is reported that the Bonanza King mine, above Trinity Center, is to change hands shortly and work will be resumed on a larger scale this spring.

Cemented Gravels Covered by Boulder Clay, Minersville.

TUOLUMNE COUNTY.

(Special Correspondence).—An Oakland company has taken a bond on the Blue Lead mine, near Arrastraville, and will begin work about May 1.——A small crew of men has begun cleaning the ditch which supplies water to the Sunnyside mine, and it is expected that actual mining operations will be in progress in a few weeks.——It is reported that a company represented by F. Chapellet has become interested in the Starr King mine and that work is to be started at an early date.——The new mill at the Maddox mine, near Confidence, has been completed and will be in operation in a few days. A cyanide plant has also been constructed.——The mill at the Draper mine, which consists of one 5-stamp and two 2-stamp batteries, is shortly to be changed to a 10-stamp mill by removing the two smaller batteries and installing another of five stamps.

Tuolumne, April 4.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—An 8-in. streak of ore has just been uncovered at the Scepter adit, near Georgetown, that assays as high as 2000 oz. silver per ton.——A. A. Hayden, manager for the Golden Glory Tunnel Mining Co., operating a group of claims on Saxon mountain, states that a compressor and machine-drills will be purchased within 30 days.——From a shipment of 20 tons of dump-matter made from the Astor mine to the Modern smelter a net settlement of $11.34 per ton in silver was realized after paying packing charges of $4 per ton, $1.50 freight, and $5.25 for smelting.——A body of ore has been uncovered in the adit being driven on the Avalanch property, at Freeland, that is from 7 to 9 in. wide, and assays 3.5 oz. gold per ton. E. M. Moscript is the owner.——From three to five cars of ore per day are being shipped from the Saratoga mine to the Modern smelter at Utah Junction.

Idaho Springs, April 2.

GILPIN COUNTY.

(Special Correspondence).—A rich discovery has just been made on the Chase property, in the Russell district. In a winze being sunk from level No. 3 a streak of ore has been cut that is from 4 to 7 in. wide and assays as high as 100 oz. gold per ton. Forbes Rickard is manager.——Ore is being shipped from the Champion-Chase mine that mills 7 oz. gold per ton. David S. Davis is manager.——The Sayre-Mammoth property was the scene last week of a promising discovery, a body of ore three feet wide having been uncovered on the fifth level that will mill better than $25 per ton in gold.

Central City, April 2.

LAKE COUNTY.

Considerable placer work is planned this spring in California gulch at Leadville. Several old-time producers are to be worked and a number of dumps are to be washed for the fine ore. At the Colonel Sellers, Moyer, and A. Y. & Minnie, the dumps are being worked and the ore shipped to the smelters.——A lease has been granted on the Baby shaft and the lessees will commence shipping lead ore at once.——Thomas Hurley and associates are shipping a carload per day of lead carbonate ore from the La Plata mine.——Operations have been resumed at the Lime mine through the old shaft.——The shaft at the Tucson property is now 1170 ft. deep. A station has been cut at the lowest level and a drift started to the ore which the management expects to cut within 150 ft.——Work has been started in the Rock shaft, on Rock hill, and a good grade of ore is being shipped.——The adit at the Alps-Aztec property is now in 480 ft., and has recently opened a small vein of smelting ore.

OURAY COUNTY.

It is reported that the American Nettie mine, at Ouray, has been sold to the Wanakah Mining Co., which owns the Bright Diamond mines. The mill at the American Nettie will be changed to concentrate Bright Diamond ore and the product will be shipped to the Hill smelter.——The mill at the Thistledown mine, on Mount Hayden, is nearly completed and the management expects to have the stamps dropping about the middle of the month. The power-plant to develop 250 hp. has been finished and the tram from the mine to the mill will soon be completed.

SAN JUAN COUNTY.

The 200-ton mill of the Ledge Consolidated Mining Co., at Silverton, has begun operations. About 400 tons of ore is in the bins and 100 tons per day will be run through the plant for the next few weeks when the output will be raised to the full capacity of the mill.——The steady producers of the camp during the winter have been: The Sunnyside, producing about 600 tons of concentrate per month; the New Gold King, 1200 tons; the Hercules, 600; the Kittimac, 100 tons, and the Iowa-Tiger, 100 tons per month. The Highland Mary is shipping 75 tons of crude ore per month.——The Gold Prince mine and mill, at Animas Forks, will be in operation again within a few weeks.

SUMMIT COUNTY.

Frank Wineland and C. W. Ellwood have secured a lease on the New York group and Johannesburg mill in the Breckenridge district.——The French dredge has begun operations for the season. The machinery and hull have been

overhauled and put in order for the season's run.——The mill at the Wellington has been repaired and is now running on ore from the dumps.——A gasoline engine is being installed at the O'Reilly property.——Operations have been resumed by the Reliance dredge and dredge No. 2 on the Swan river.

TELLER COUNTY.

The Union Leasing Co. has secured a 5-year lease on the property of the Black Belle Gold Mining Co., in the Cripple Creek district. The drift of the leasing company has already cut the Black Belle ground opening some fair ore. ——The General Leasing Co., operating north of the Davenport shaft of the Doctor-Jack Pot Mining Co., is driving north on a 3-ft. vein. Several shipments of screenings have been made.——During the month of March 50 cars of $20 ore have been shipped to the valley mills from the Jerry Johnson mine and 1100 tons of low-grade oxidized ore treated in the local plants.——A 12-in. air-pipe has been placed in the Rexall shaft at Victor to facilitate ventilation. ——The Stratton's Cripple Creek Mining & Development Co. is installing a new compressor at its Abe Lincoln mine and the shaft will be sunk from the 700 to the 800-ft. level. W. J. Hill is operating the property under lease.——The El Paso Consolidated Gold Mining Co. paid a dividend of $24,500 on March 31.——The Isabella Mines Co. installed a steam hoist at the old McDade shaft.

IDAHO.

IDAHO COUNTY.

W. H. Stowell and J. T. Omo, of Spokane, have purchased the South Fork mine, in the Elk City district, and organ-

The Coeur d'Alene, Idaho.

ized the Elk City Mines Corporation to operate the property.——A two-year option has been secured on the North Star group, southwest of Hump, by Thomas R. Sales, of Salt Lake. The price is $60,000 to be made in four payments.

SHOSHONE COUNTY.

The adit on the Black Bear Fraction, operated by Peter Bernier, of Wallace, opened a 5-ft. body of lead ore.——Work has been resumed on the Index property, near Kellogg. A 600-ft. adit is being driven that will tap the vein at a depth of 300 ft.——Heavy snowslides at the Paragon group swept $15,000 worth of machinery down the canyon and it is the intention of the management to replace this as soon as the snow melts.——A meeting of the stockholders of the Bunker Hill & Sullivan company has been called for April 14, when a proposition for a compromise with the Federal company will be submitted.

MISSOURI.

JASPER COUNTY.

At Carl Junction the A. & D. Co. is getting ready to put the old Ishpeming tract in operating condition. A large plant will be built. The lease is well developed.——A new mining camp is being opened at Cliffwood near Neck City, where the Cliffwood company has a new 150-ton mill ready for operation. The shaft is down 160 ft., where ore is found in a hard white limestone which requires no timbering. The ore was first found at 87 ft. Another mill is also to be erected in the camp by the Sand Hill Co., which has a shaft in ore at 170 ft. and a number of drifts opened. ——A third company is Coats Bros., who have a shaft in ore at 178 ft. Farther to the east is the northwest corner of the Neck City camp where the rich Quick Seven and other properties are operating with great success.——Operations near Carthage are promising and a number of companies are active. The Tri-City company is sinking to 200 ft., where a sheet-ground run similar to the Joplin and Webb City fields was penetrated in drilling.——The Vesuvius company is building a chat-mill to operate on the tailing from the ore which was mined at the 170-ft. level. The regular 250-ton mill already on the lease will still operate on the ore as taken from the ground.——The North Pole M. Co. has one of the few lead prospects in the Carthage field, on the Mevey farm. The company has been working the upper levels, but also has a prospect in lower ground and is sinking the shaft to the 220-ft. level.——A company operating near Porto Rico on a lease formerly a portion of the Ground and Irwin tract has a good prospect in a shaft at 182 ft., and is building a 200-ton plant. The ore is blende with a slight trace of galena. It is claimed six drill-holes showed the same formation. The face of ore is 16 ft. high and assays better than 6%.——Ed. Mallet and others have a good prospect near Zincite at 90 ft. in hard ground. The ore is treated in a custom mill.

NEVADA.

CLARK COUNTY.

The cross-cut on the 100-ft. level of the Capital mine, in the Eldorado district, has opened a 2-ft. shoot of high-grade ore. Over $100,000 has been taken from the surface workings in ore assaying from $150 to $400 per ton.

ESMERALDA COUNTY.

The annual report of T. G. Lockhart, president of the Florence Goldfield Mines Co., mailed to stockholders April 2 from the office of the secretary in Denver, with the checks for the 10c. dividend declared in February, shows that the company during the year ended December 31, 1909, made a net profit of $232,050. Two dividends of 10c. per share each totaling $210,000, were paid during the year, leaving a balance in treasury on the year's business of $22,050. Cash on hand December 31 is shown as $122,470. During the year the company handled 34,824 tons of ore of an average value of $18.42 per ton in its mill, and shipped to smelter 173 tons of an average value of $287.54. The ore that was handled in the mill was of a gross value of $641,585, from which an extraction of $591,036, or 52.12%. The net ore returns for the year are given as $533,617, the sum of $107,412 being assessed against the returns for marketing ore, including freight charges, smelting, mint charges, etc. The total expenses for the year, chargeable to mining, development, and including the above $107,412, are given as $300,551, which gives a total cost per ton for the ore handled of approximately $9.——The Goldfield Alamo company has declared another dividend of 3c. per share, payable to stockholders of record April 20. As there are 700,000 shares of stock issued, this dividend will amount to $21,000. A dividend in the same amount was paid February 1.——The

Knickerbocker lease on the Commonwealth has at last reached ore in the cross-cut from the old company adit, this being the downward extension of the ore-shoot that was cut some weeks ago in the old workings near the top of the hill. The ore now picked up some 75 ft. below where it was found above is 4 ft. wide, and composed of an oxidized sugary quartz.

LANDER COUNTY.

(Special Correspondence).—The Austin Manhattan Co. has removed the steam plant from the Frost shaft to the Ophir shaft, and will retimber the latter to the 400-ft. level. The new 60-hp. gasoline hoist will later be installed at the Ophir shaft. A contract has also been let to sink a 100-ft. shaft on the Midnight claim on Midas flat.——The King Midas has made the final payment of $12,000 on the Rowdy group and will commence more extensive operations.——The Roosevelt lease of the Maricopa Mines Co. is down 150 ft.——The Shoshone Quicksilver Co. is opening large reserves of cinnabar ore in its property near this city. The ore is said to average over 3% quicksilver, and the company is to install furnaces of 100 tons capacity this summer to retort the ore.——The Maricopa Mines Co. has installed a hoist and compressor at the Patriot and is arranging to run two drifts between the 650 and 800-ft. levels.

Austin, April 1.

LINCOLN COUNTY.

Work has been resumed at the Centenniai Pioche after a temporary shut-down. Murray C. Godbe is manager.——Repairs on the railroad are being rushed and it is understood that trains will be in Pioche about May 1.——The Golden Prince, Gold & Silver Prince, and Prince Consolidated, are all blocking out ore awaiting the completion of repairs to the railroad.

LYON COUNTY.

A new 10-stamp mill is to be installed at the Ramsey-Comstock mine, near Ramsey, as the present plant is too small to handle the output. The mine is opened to a depth of 400 ft. though all the stoping is being done above the 160-ft. level. Over $20,000 worth of bullion has been taken from the property with a small rotary mill.

NYE COUNTY.

The Tonopah Extension Mining Co. has purchased the holdings of the Red Rock Mining Co. and the McKane Mining Co., in the Tonopah district. The properties total about 200 acres, giving the Extension the largest acreage in the district. The Red Rock Consolidated ground lies to the south and west of the Extension holdings, while the McKane is situated west and north. The new ground will be prospected through the Extension workings.——Drifts have been run on the shoot recently opened on the 275-ft. level of the MacNamara mine for 50 ft. showing the vein to be over 2 ft. wide. When the raise from the 300-ft. level is completed the ore will be handled easier and more rapid progress made.——Operations were suspended a few days at the Midway to repair the boilers.——At the Tonopah Belmont the face of the east drift on the 1000-ft. level is now in a good grade of milling ore averaging about 16 ft. in width.——The Montana-Tonopah Mining Co. has purchased a two-thirds interest in the Miriam group for $5000. The ground joins the northern endline of the company's holdings and contains about 50 acres. The ground is unpatented and no ore of commercial grade has been found on it.——Plans are being formulated for the reorganization of the Montgomery Mountain property, in the Bullfrog district.

STOREY COUNTY.

The retimbering of the main Sutro tunnel has been practically completed and the stave-pipe carrying the hot water from the C. & C. and Ward shafts has been covered to protect it from any falling rock.——Development work at the Comstock-Phoenix mine, on the Brunswick lode, is progressing rapidly, and a large amount of milling ore is being opened. A contract has been let to sink the winze from the 350 to the 450-ft. level. A drift has been started west on the vein to open the four shoots which have been found in the upper levels.——Work on the 2300 and 2400-ft. levels of the Mexican mine is opening ore that assays from $15 to $70 per ton.——Joe Dletrich has taken a lease on the Best & Belcher croppings and surface workings and has already made good progress in his prospecting work. Some good leads have been found and are being followed in hopes that they will develop into larger orebodies.——The raise on the 1750-ft. level of the Consolidated Virginia is up 15 ft. in ore assaying about $8 per ton. From the stope on the 1800, 190 cars per week of $7 ore is being mined.

WHITE PINE COUNTY.

(Special Correspondence).—It is reported that a merger of the Ely-Centennial, Ely-Calumet, and McDonald-Ely properties is projected.——Ely-Consolidated is driving an east drift from the American shaft, and is in 200 ft. The vein has been opened by a winze from the west drift showing a high value in lead with a fair amount of gold.——Ely-Centennial has its new compressor-plant in action and the drills are breaking 12 ft. per day in the adit.——It is reported that the Cole-Ryan interests are considering the acquisition of the Challenge and Aurora properties. The Challenge joins the Jupiter mine of the Cumberland-Ely estate.——The Richardson and Badger leases are maintaining good shipments of high-grade silver-lead ore.

Ely, April 2.

OREGON.

BAKER COUNTY.

(Special Correspondence).—One of the most prominent mines of recent development in eastern Oregon, is the Rainbow, situated in the Pedro mountains, by wagon-road, 38 miles southeast of Baker City, in the Mormon Basin district. It is owned by the Commercial Mining Co., with head office in Portland. The vein is on a contact between granite and limestone, which an adit cuts 180 ft. below the apex. From an inclined shaft, sunk from the adit-level, three other levels are driven on the vein, opening it for a total distance of 1000 ft. Where the vein is cross-cut by the adit, it is 300 ft. wide. On the limestone foot-wall, there is a porphyritic intrusion, silicified on both sides into bodies of quartz, which contain gold from $3.50 to several hundred dollars per ton, with an average value of $23. These orebodies are from 6 to 40 ft. wide. The remainder of the vein filling back to the hanging wall of hornblende granite, varies from 100 to 300 ft. in width, and averages, in gold, about $3 per ton. Further exploration now in progress in this mine is with a view to developing additional tonnage of high-grade ore, and determining the commercial possibilities of the lower grades, for the entire distance across from limestone to granite. About $200,000 have been taken from this mine to date. The Rainbow holdings cover 200 acres of mineral ground and 480 acres of timber. The property is equipped with a 10-stamp mill and Wilfley tables. From the mine to the mill the ore is conveyed by aerial tram a distance of half a mile. Machine-drills are, for the first time, being installed, and preparations are on for the operation of this mine on a large scale when the Ox Bow power-plant on Snake river is completed, whence electrical energy will be brought in 40 miles. H. C. Wilmot is general manager, and W. E. King, managing director.——On the same dyke-system, and with geological conditions similar, another property, a mile west of the Rainbow, is rapidly gaining prominence. This is the Humboldt, owned by the Humboldt Gold Mines Co. About 18 months ago this property was acquired by the present owners. The development now consists of a 200-ft. vertical shaft, drifts, crosscuts, and raises, aggregating 4500 ft. Orebodies have been proved in these workings covering areas from 70 to 600 ft. long and to the extent of 40 ft. in width. They occur in shoots or lenses. The milling ore averages $9 per ton, principally gold. On the lower level it is base but of higher value, lead, zinc, antimony, and a little tellurium appearing. Equipment at the Humboldt comprises a modern hoist and sinking plant, a 10-stamp Allis-Chalmers mill and six Johnson concentrators. Of the milling ore, 65% of the assay value of the heads is saved by amalgamation. The concentrate assays about $80 per ton, and bring the total savings up to 93 per cent.

Baker City, April 2.

UTAH.

JUAB COUNTY.

(Special Correspondence).—The Yankee Consolidated Mining Co., operating in the Tintic district, recently levied an assessment of 3c. per share on its stock, and at the sale of delinquent stock, on March 21, only 5700 shares were sold. In the course of development ore shipments have been made in small lots, but the proceeds have not been sufficient to pay expenses. Exploration is being carried on from levels that connect with the new 900-ft. shaft which was sunk close to the main adit. This shaft, which has three compartments, is to be sunk deeper, an electric hoist for this work having been purchased from the Gallgher Machinery Co. It is capable of hoisting from a depth of 2500 ft. B. N. Lehman has the management of the property.

Eureka, April 1.

The No. 1 shaft on the Iron Blossom mine, at Tintic, is down 1450 ft., and it is reported that a cross-cut on one of the lower levels has opened a shoot of high-grade gold ore. About 75 tons per day of second-class ore is being shipped from this shaft to the smelter. The No. 3 shaft is expected to open the orebody worked on the 280-ft. level within the next few weeks.——Two carloads per week of first-class ore are being shipped from the Gold Chain property. The management is now running three power-drills in development and stope work.——The winze recently sunk from the 260-ft. level of the East Tintic Development Co.'s property cut a small vein of ore that assays 58 oz. silver and 53% lead.

SALT LAKE COUNTY.

In an action filed in the district court, Walter Steadman asks damages from the Garfield Smelting Co. of $13,720 for injuries to his farm and stock and also to the farms and stock of 13 other farmers near the Garfield smelter, alleged to have been caused by the smoke and fumes from the smelter during the seasons of 1908 and 1909. The claims of the 13 other farmers were assigned to Steadman.——The Bingham Mines Co. is installing a complete electric generating plant near the Dalton shaft which will furnish it with power and light.——The Utah Metal Mining Co. has commenced work in the face of the 3000-ft. tunnel from Middle canyon, and will drive it 8000 ft. farther under the orebodies on the Bingham canyon side of the range. Since the company started active work last fall its forces have been employed installing the power-plant and other machinery, erecting new buildings and enlarging the old tunnel to 8 by 10 ft. At this time only two shifts of five men each are being worked in the tunnel, but with the arrival of the electric locomotive and the motor to operate the ventilating fan, three shifts of seven men each will be employed upon that work, pushing the work at the rate of nearly 400 ft. per month. Making allowance for unexpected delays, it will take about two years to complete the tunnel. ——Through experiments, re-arranging of machinery, close calculations, and a better understanding of the ore, the Utah Copper Co. is fast increasing the efficiency of the plant. This increase in efficiency has reached a point where it seems almost certain that the present mills of the company may soon be able to handle 20,000 tons of crude ore per day. At present the mills are handling close to 13,000 tons of ore.

SUMMIT COUNTY.

The directors of the Daly West Mining Co., at Park City, have just posted the regular dividend of 30c. per share. This is payable April 20 to stockholders of record April 10. Since the first of the year the company has been increasing its profits and adding to its surplus. The March earning of the company is estimated at $35,000 by the manager, Ernest Bamberger. In January, the net earning was $28,000, and in February, over $29,000.——At the Iowa Copper property the Spooner drift is being driven on a seam of carbonate ore. Nels Peterson is in charge of the work.——In the report of the Daly-Judge Mining Co. for 1909, the manager states that the mill ran one 8-hr. shift per day throughout the year, the total receipts were $437,631, and total expenditures, $347,590. Some $100,918 were derived from the operation of the zinc plant which was run on ore both from the mine and dumps. Development work, exclusive of prospecting, amounted to 5165 ft., while that in prospecting alone approximated 1700.——Conditions at the New York Bonanza have been improving recently and indications point to the resumption of shipping at an early date.——The cross-cut on the 900-ft. level of the Silver King Coalition opened a good body of shipping ore.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The North San Poil mine has been leased to W. M. Crummer and associates for two years with an option to purchase. The same parties have obtained a lease of 50 ft. of the north end of the San Poil mine, which adjoins the North San Poil on the south.——The Republic Mines Corporation is meeting with success in working the Surprise vein, on the Pearl group, and shipping 5 carloads of ore per week.——Negotiations are pending for the purchase of 20 acres of bench land on the western limit of the city of Republic for a mill-site, and there is considerable talk about establishing a custom cyanide plant.——It is reported that arrangements have been completed for a power-plant to be erected near Godfrey, on Kettle river. ——A cross-cut is being driven from the No. 3 adit of the Belcher mine to intersect the orebody developed on the No. 2 level.——A new body of lead-copper ore has been opened in the Kettle River mine, near Orient. A carload of machinery for the concentrator has been received.

Republic, April 1.

OKANOGAN COUNTY.

A large body of ore is reported to have been discovered in the mountains adjacent to Sinlahekin valley, on the Iron Mountain group of claims. Surface samples of ore are said to have assayed in gold and silver from $8.60 to $25.80 per ton.

CANADA.

BRITISH COLUMBIA.

The management of the Lucky Jim mine, in the Kaslo-Slocan district, is preparing to ship 100 tons of zinc ore per day as soon as the railroad will furnish the cars. The company is arranging for the erection of a 100-ton concentrator at Kaslo in two 50-ton units.——A high-grade orebody has recently been opened in the Rambler-Cariboo property.——Price & Burgess have opened an orebody on the Iona property in the Ymir district.——A shipment of 100 tons of ore has been sent out from the Aurora mine on the west side of Moyie lake. The ore assays 28% zinc and 25% lead, with 2 oz. silver per ton.——The Big Casino and Bullfrog groups, in the Stewart district on Portland canal, have been sold to Vancouver and Victoria capitalists.

ONTARIO.

The Lewisohns have taken up their option on the Wettlaufer mine, at Cobalt, and are to add a 12-drill Rand compressor to the equipment.——The Ontario Government has purchased the nugget that made the Cobalt Gem Mining Co. famous for $5000, and now has it on exhibition in the parliament buildings at Toronto.——The first unit of the Cobalt Power Co.'s Hounds Chutes plant has been completed and water turned through the canal, generating 1000 hp. This is Cobalt's nearest power-plant, being only four miles from the Waldman mine.

MEXICO.

CHIHUAHUA.

The American Smelting & Refining Co. has the first of the two new furnaces at the Chihuahua plant completed and in operation. The second one is to be blown in some time in May. This will make five furnaces in the plant with a total capacity of 750 tons per day.——The steel work for the Palmilla mill, at Parral, is well under way and it is expected that this portion of the work will be completed in June.

SONORA.

At a recent meeting of the stockholders of the El Tigre Mining Co. the number of directors was increased from seven to thirteen. A number of stockholders and directors recently visited the property and plans for the doubling of the output of the mine are now being considered.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. Morgan Clements is at Butte.

W. F. Ferrier has gone to New York.

C. L. Wilson was in San Francisco this week.

Leon Dominian will be at New York April 15.

E. S. Pettis has returned to San Francisco from Sonora, Mexico.

F. P. Bodfish of Victor, Colorado, was recently at Twin Falls, Idaho.

W. A. Stevens, of San Francisco, is at Jarbidge, Elko county, Nevada.

R. B. Lamb has completed his work on the La Fortuna property near Chihuahua, Mexico.

G. E. Stephenson, general manager for the Palmarejo & Mexican Gold Fields, Ltd., was in San Francisco.

George W. Myers, of San Francisco, representing the Chrome Steel Works, is on a business trip through Arizona and Mexico.

C. L. Constant, Jr., has just returned to New York from Idaho, where he has been engaged in examining some copper properties.

H. C. Wilmot has been appointed manager for the Commercial Mining Co., Rye valley, Oregon, and has closed his Salt Lake office.

Maitland F. Kindersley is arriving in New York from London on his way to Peru, where he goes to examine a copper property.

Philip W. Henry, Eowin O. Holter, Marvyn Scudder, W. B. Devereux, Jr., and H. A. J. Wilkens have formed the Mines Management Co., with offices at New York City. The purpose of the company will be to report on mines, organize companies, and undertake the management of properties.

MARCH COPPER REVIEW.

By M. E. Appelbaum *

During the month of March a fairly satisfactory business was transacted with domestic consumers, and one or two large lots sold for export, but on the whole the transactions show a marked falling off as compared with previous months. The statistics published both in New York and abroad show clearly that consumption and production are running about even, but the consumers are much disappointed to find that the shut-down of the mines and curtailment of the production is not shown in the producers' figures, and have made up their minds that as long as production continues at such an enormous rate a hand to mouth policy is the safest. Assuming that the domestic deliveries will continue at the high rate established during the last few months, that the exports will represent actual European requirements, and that even these total deliveries will not come up to the production, it is hard to figure on a higher copper market. The immediate outlook, therefore, for the metal is for a steady market around the present level since the visible supply here and in Europe is quite sufficient to take care of any small improvement in business. The general uncertainty in regard to the labor situation, the poor market for bond issues, which in turn holds up construction work, and the general unrest, has made the consumers of copper very conservative. They are not in a receptive frame of mind as to buying liberally and show no disposition to take over part of the surplus carried by the producers. On the other hand, this feeling would easily be overcome once the trade was assured that a curtailment in production of 5 to 10% was taking place. The figures for the month of March, to be published on April 10, should show deliveries of about 45,000,000 lb. for export and 70,000,000 to domestic consumers, making a total of 115,000,000.

*President of the New York Metal Selling Company.

EDITORIAL.

IMPORTS entering duty free amounted during the last fiscal year to $600,000,000, being 47 per cent of the total merchandise coming to the United States from foreign countries. Of this total tin and tin oxide amounted to $26,010,356, and copper and its manufactures to $37,763,798.

CHINA as an exporter of pig iron and a serious competitor for a share in the world's business, is foreshadowed in the article on the Tayeh iron mines by Mr. A. J. Seltzer of the Imperial Mining College, at Wocchang, appearing in this issue. That the great mineral resources of the 'Middle Kingdom' are already being developed in a serious way, is not always realized.

NINETEEN YEARS is not a long time in Europe or even in America, but in South Africa it spans the time between savagery and civilization. It practically covers the history of the Rand, and an interesting and impressive history it has been. The *South African Mining Journal* began in January 1890 as the *Mining and Metallurgical Review* and has grown with the great gold mining district it so ably represents. On March 12, it issued a handsome special number celebrating its nineteenth anniversary. Much of interest regarding the Rand is told, and the growing importance of Rhodesia and the 'outside districts' is also illustrated. The *Journal* has a record of which it is justly proud, and across the seas we extend our congratulations and our good wishes for its future.

INTERESTING details as to the action of carbon and cellulose in cyanide solutions are given on other pages of this issue by Mr. A. J. Clark and Mr. W. J. Sharwood. More than one metallurgist has discovered to his cost that ashes carelessly thrown over the dump cause serious losses when later the dump is re-treated. At the Oriental Consolidated in Korea, it was necessary to jig out the ashes before treating certain old dumps. At the Homestake some puzzling initial failures in extraction were traced to ashes dumped into an open pit and finally drawn through the chutes with ore. Mr. W. A. Caldecott has called attention to the bad effect of charcoal mixed with lime burned in old fashioned kilns when the latter was used to neutralize acid solutions. It has long been known to geologists and others that black shales precipitate gold from underground waters, but quantitative expression of this effect of organic matter has been lacking. The paper will be read with wide interest because of both its practical and scientific bearing.

ELECTRIC REDUCTION of iron ore, a subject comprehensively discussed in this issue by Mr. Joseph W. Richards, the accomplished professor of metallurgy in Lehigh University, is a matter of large interest in Canada and on the Pacific Coast. In the eastern and southern centres of pig-iron production where fuel is abundant, there has been no need to resort to the electric current. Since it has been in these districts naturally, that the most of the American study of the metallurgy of iron has taken place, possibilities in the use of the electric current have been overlooked. Both the North and the West have ore and water-power and in time the latter may be expected to recompense for the scarcity of fuel, in metallurgical work as well as in transportation and general manufacturing.

SWEDISH geologists and officials are making elaborate preparations to entertain the eleventh session of the International Geological Congress in Stockholm, next August. An interesting program and an attractive list of excursions are offered. The well known hospitality of the Swedish people is sure to make the occasion enjoyable entirely aside from its professional interest. We are glad to note, though, that especial effort is being made to give point and purpose to the discussions. The Congress was formed to introduce as large a measure of uniformity as possible into international geological nomenclature and literature. The great plan for a one to one million scale, international, geological map was formulated, and the map is now in process of publication. Questions of correlation and nomenclature have been repeatedly discussed and much in the direction of simplification has been accomplished. More, however, has been proved impossible.

With each meeting, the regional character of geological development has become apparent and at the session held in the City of Mexico in 1906, it became clear that of the original purposes of the Congress some had been accomplished and others must be abandoned. The social features of the gatherings had been gradually accentuated at the expense of the scientific sessions, until a change of some sort was clearly desirable. The Congress was in danger of being smothered by the hospitality of its successive hosts. Accordingly it was decided to meet thereafter at intervals of four rather than three years, and the character of the program was given earnest attention by the Council. As a result the Stockholm session will be notable, among other things, for the presentation of an elaborate compilation of data on the iron-ore resources of the world. This work was begun by the Executive Committee early in 1908. Requests for information were sent to geologists and mining engineers in every country and the responses were so numerous that the report occupies 1100 pages with numerous illustrations and maps. It will be laid before the Congress for consideration and is sure to bring out much illuminating discussion. Another piece of work undertaken by the Executive Committee, relates to climatic changes since the last glacial period. This subject, while of less immediate economic importance, is of equal scientific interest and the discussion may be expected to clear up many misunderstandings. Altogether the session promises to be extremely useful as well as pleasant and we congratulate those of our fellow workers who may find time to attend.

Geological Survey Building

Estimates have been submitted at Washington for a fire-proof building to house the Geological Survey and related bureaus. That such a building was not provided long ago is another evidence of the uneconomical and unbusinesslike manner in which Government affairs are conducted. Considered on its merits, absolutely no objection can be urged against prompt provision of adequate and safe quarters for this and other branches of the Government service. Unfortunately the matter is not considered upon its merits. Last year it was defeated by the arbitrary and unexplained opposition of one member of Congress, Mr. J. R. Mann, of Chicago. The reason that the Government continues to rent inadequate buildings at high profit to private owners hather than to build, substituting low interest charges for high rent, lies in part in the fact that Washington office buildings are largely owned by members of old families that are in position to dispense coveted social favors to new Senators and Congressmen. In this way ties are formed which, quite unconsciously perhaps, influence results. Another reason is the inertia that must be overcome to secure any legislation. The major difficulty, however, lies in a profound disagreement between the Senate and House over a building program.

A few years ago the Senate secured a report and plans for the future development of Washington along artistic lines, from a commission of architects, engineers, and artists of the highest repute. Since then it has consistently attempted to secure the adoption of this plan and has made repeated efforts to induce the House to consent to the purchase of the necessary land. Mr. Cannon and other leaders of the House have opposed this, urging that a general purchase of land would require a bond issue. Washington is unique among American cities in not being allowed to go into debt. It is admitted that buying the land as needed involves paying prices which increase with each purchase, but the House leaders have held that prices are already inflated and seem to prefer the chances of future to present bargaining. They have been roundly abused and their opposition has been held to reflect an unreasoning opposition on the part of Mr. Cannon to anything artistic as being a mere fad. However that may be, there is at least one good reason for their stand.

Much land in Washington is owned by Senators and there is a not unnatural profit in selling it to the Government. Not all Senators have the high sense of honor possessed by Mr. F. G. Newlands, of Nevada, who, when land in which he had an interest was bought as a site for a 'Hall of Records', insisted that his share should go to the Government at the price he had paid, and refused to make any

profit from the transaction. This particular piece of land, as it happens, was that selected last year for the proposed Geological Survey building, and Mr. Mann has intimated that it was bought following great public clamor for a 'Hall of Records', which clamor significantly disappeared after the land had been sold to the Government and profits taken on the transaction. All this explains a not unnatural and human feeling of resentment on the part of members of the House, but it does not justify opposition to an important and much-needed public improvement such as the building for the Geological Survey. That highly useful Bureau needs better and bigger quarters, and it is of large importance to the mining industry throughout the country that its invaluable records be preserved from destruction.

Validate the Land Withdrawals

As is well known to our readers Mr. Roosevelt while president, and Mr. Taft after succeeding him, withdrew from all forms of entry large tracts of public land supposed to contain mineral deposits or to be suitable for water-power development. It is less well known that such withdrawals by executive proclamation have been made at intervals for more than forty years. The power, it is true, had never been used in a wholesale manner until within the last few years. Recently it has been questioned. No objection would probably have been made if only lands needed for Governmental purposes had been withdrawn. In many cases, however, there has been no pretense even that this were true. Believing that the present land laws were defective and that public interests would suffer if the land remained subject to entry, the President has withdrawn various tracts "pending legislation" and has recommended to Congress the changes that he considers necessary. There is wide disagreement as to these changes.

In our Washington letter this week we present the text of the Administration bill relating to phosphate, oil, asphaltum, and natural gas bearing lands. In the Discussion department is a criticism of this bill by Mr. Roswell H. Johnson, an experienced engineer operating in the Oklahoma oilfields. Mr. Johnson is an especially competent critic since he is in complete accord with the fundamental purpose of the President and has had experience in the only territory where operations are now conducted under leases administered by the Secretary of the Interior. We believe that there is general agreement with the Administration in what it is trying to do, preserve the public domain from spoilation by individuals at the expense of the people as a whole, but there is quite as general disagreement as to the best means of doing this. Many strongly advocate a leasing system; others propose ceding the lands to the States as representing the people of the communities most affected; still others argue for sale by either the State or the Federal Government, under various restrictions as to title. It is obvious that there is no consensus of opinion as to what should be done though there is wide interest in the matter. California is especially concerned in the status of the oil lands. Idaho has a major interest in phosphate. Utah, Colorado, Wyoming, and Montana, especially, are concerned with the disposition to be made of the coal lands. All the Western States have a large stake in the conditions under which water-power shall be developed in the future, and every State in the Union has some concern with the solution of the problem. It is not unfair to claim for the Western States the largest and most direct interest, and yet even in the West there is no general agreement as to what should be done. If the matter be settled now it must be on the basis of Eastern sentiment, and the people east of the Mississippi are not much, if any, more united in regard to plans than are those west of that river.

We are not disposed at this time to argue for any particular solution of the problem, nor do we believe it necessary to further impress its importance. We gladly open our columns for its general discussion and we suggest that the proper use and disposition of the public lands is the question most worthy of prominent place on this year's programs of the American Mining Congress, the Trans-Mississippi Congress, the Irrigation Congress, and the various other bodies which meet annually to assist in formulating public opinion. Let there be full and frank discussion from all points of view and we are sure a sound conclusion will be reached. If, in turn, Western public opinion unites on a program which is logically defensible, there need be no fear that Congress will disregard its mandate.

In the meantime it is of first importance that the present status be maintained. There will be no need of locking the stable door if we defer till after the last horse has disappeared. While a few remain, it would be well to give a key to the President, that terms of sale or hire may be debated with profit. Mr. Taft has stated his own doubts as to the legality of the withdrawals. That is a point about which lawyers differ and it would be well to resolve the doubt in favor of the general good. The Senate committee has reported a bill validating the withdrawals which have been made and specifying the terms and conditions under which they may be made in the future. It is required that all lands withdrawn shall be reported to Congress each year for such action as may seem wise. This temporary withdrawal of land will to some extent check development and that is an added reason for prompt settlement of the difficulties. Temporary inconvenience is the price we pay for past laxity and for being at present uninformed as to facts and ununited as to policy. Any withdrawal can hardly operate to extinguish rights where entry was made before the land was withdrawn and in those cases where entry was made in good faith after the land had been announced as withdrawn, it is probable that the entrymen will, in some way, be given preference when the land is finally re-opened to entry or lease. In view of the general complexity of the case some such solution only would be fair and just; and the American people are never willingly unfair. The immediate need is to remove all possible ambiguity by validating the withdrawals, then to get together on a carefully considered and consistent scheme of land control or lease.

The Tayeh Iron Mines

Written for the Mining and Scientific Press
A. J. Seltzer

The mineral wealth of ancient China is shrouded in mystery. In China, as well as in almost all parts of the outside world, fabulous, or at any rate, almost incredulous tales are spun by the score, concerning China's hidden treasures. Doubtless the truth of some will be demonstrated in the not distant future, but today they remain mysterious and unsolved. I dare say, the magnitude of some of them, consigns them to the land of perpetual fairyland. That there are gigantic deposits of ore and mineral, of all sorts and descriptions—and most especially of coal and iron ore—no one who has ever traveled extensively in China will deny, but there is no means to justify even a conjecture as to the quantity. Only an exceedingly small amount of prospecting or exploitation has ever been done, and even a smaller number of mines are now being operated.

The Tayeh iron mines and quarries have been worked since about 1888. This interesting iron range is situated in the eastern part of the Province of Hupe, 510 miles inland from Shanghai, and 26 kilometres southeast of the mighty Yangste river. It is one of the largest iron orebodies in China and one of the few that is being worked. The Hanyang Iron & Steel Works, at Hanyang, 145 kilometres up the Yangste Kiang from Tayeh, are being furnished with 500,000 metric tons per year from these mines and 125,000 tons are also exported to Japan. The Tayeh range is a contact deposit between a compact close-grained diorite on the north and very pure, almost white, marbly limestone on the south. The diorite being very hard and not seriously affected by weathering, has not been eroded to any great extent and lies snugly against the iron ore to its maximum height. The limestone has been seriously eroded and in many places has left the hematite near the surface; the richest part of the range has a southeast trend, but just beyond this rich part, the vein is almost barren and runs practically due east and west.

The main orebody appears in two symmetrical conical hills, each being 250 metres in height, about 50 metres in diameter at the top, and 200 at the base. The vein connecting these two hills is 70 metres wide and the distance between the bases of the hills is about 200. The ore in these two hills is a good hard hematite. It is necessary to drill and blast the greater part of it. The drilling is all done by hand and a poor driller is Mr. Chinaman. The German engineer in charge informed me that it was next to impossible to persuade a Chinese that the Western method of pointing holes is superior to and far more efficient than his own. The Chinese drillers insist on carrying out their own ideas in the matter; as they do in most things. I observed numerous holes pointed in such a manner that the least, rather than the greatest, quantity of ore would be shattered. I was informed that the drillers were instructed many times a day, in regard to the proper pointing and even have the holes marked for them, but ignore the marking and place the holes according to their own ideas. The engineer informed me that one good German driller would break as much ground as eight or ten Chinese.

The work in these hills is all open-cut. Levels are made at convenient but irregular distances. There are four levels from the ordinary ground level to near the top of the hills. The method of procedure is to go in on the limestone contact and cut out slices from one bench to the next higher, then cut back until a floor is made on this level, following this by taking a vertical slice to the level above, and so on. The hill-side presents the appearance of a gigantic stairway. As the ore is blasted, it is carried to inclined planes, in wicker baskets, two of which suspended from a 6-ft. bamboo pole are carried on his shoulders by each coolie, and dumped into one-ton

cars, which are sent down the inclined planes and trammed to the loading station by coolies. There are four inclined planes at these two hills, two at 15°, one at 18, and the fourth at 35. The descending full car pulls the empty one up. A hold-back station or break is required at the top of each plane, however, and the 35° incline has a truck and a box arrangement, so that the full car slips into it and is held horizontal in its descent. The 35° incline is 250 metres long, the 18°, 220, and the 15° planes about 300. The steepest incline is at a uniform slope of 35° but the others are at less than 18 and 15° near the top, and also near the bottom. This is to prevent the full car from attaining too great a velocity at the beginning of its descent.

The vein is barren for six kilometres southeast of the two hills. It then appears in a third hill of ore—this being somewhat larger than either of the others. The ore here, however, is of not as high grade and contains some limonite and about 7% manganese. About 400 tons per day are taken from this hill. At this point the limestone contact contains a very pure white limestone, and it is here that the limestone for

the Hanyang works is quarried. Following the vein from the opposite side of these two richest hills it is found to be practically barren for three kilometres, and then a small hill, containing a poor grade of ore is found. Beyond this hill three more occur in close proximity. These three hills apparently contain ore, but as little prospecting or exploitation has been done upon them, no accurate statement as to quantities can be made. It is quite evident, from what ore that can be seen, that the quality is poor. Beyond these three hills, nothing is apparently known of the iron content of the range.

It is safe to say that the iron can be traced through the range for 16 kilometres. Of this distance along not more than 4 kilometres is the ore rich enough to be worked. The richest ground has an extent of not more than one and one-third kilometres. I was informed that the company has done practically no prospecting or exploitation, and practically nothing is known of the depth of the vein, or its iron content, other than at the three hills that are at present being worked. No deep drilling has been done and the width of vein and its grade below even the ordinary ground level is unknown. The only information obtainable in regard to the quantity of ore is that the ore in sight is sufficient to maintain the present output about 70 years. There are indications which lead me to believe that the vein is not only richer at depth, but also wider. The three hills now being worked are solid iron ore, and it is, indeed, a striking spectacle to see the thin contact of limestone cut away and the huge mass of bright hematite exposed to view, for a height of 250 metres. At present the total output from the three hills is about 1200 metric tons per day, but it is soon to be increased to over 1600.

When the ore-cars reach the bottom of the inclines, they are pushed by coolies to the head of the loading station, where they are sent down a short incline and dumped to the ground from a steel trestle. From here the ore is again loaded into small cars and pushed over to the tipples and dumped from an ordinary coal tiple, into the 11-ton cars and transported to the Yangste Kiang in trains of 12 cars each. Here it is loaded on the company's lighters and towed up the river to Hanyang, by steam launches. One launch tows two lighters, containing 350 tons of ore each—one lighter being roped alongside, the other towed astern.

At these mines there are about 3000 Chinese employed, mostly men, though there are several hundred boys. The following is the schedule of wages per day of ten hours: miners, 250 to 300 cash, equivalent in United States currency to 8 or 9.5c.; loaders, trammers, and car tippers, 100 to 150 or 3.25 to 5c.; small boys and old men who carry the ore in small wicker baskets, from 80 to 120 cash, or 2.65 to 3.65c. The cost of mining one ton of ore is 270 cash, or 9c. gold. Stripping costs 30 cash, or 1c. gold, per ton, and tippling costs 10 cash, or 0.33c. per ton. Most of the work is done by contract and one large contract is sublet to a large number of small contractors. This eliminates a great many labor difficulties which is no small matter in China. It also prevents an exhaustive drain on the patience, temper, and optimism of the foreigner. There is, of course, no scarcity of labor in China, but the efficient handling of Chinese labor presents difficulties and peculiar problems that are rather mysterious to the average Westerner. The Chinese laborer resembles the Mexican in many respects, and especially, in that he will work enough days per month to provide sustenance, but no more. The average number of the days per month which the 9000 men employed at these mines at the Hanyang Iron & Steel Works, and the Pinghsiang coal mines and coke ovens work, has been found to be 21 days.

The following are the analyses of the ore and limestone at Tayeh and the raw and finished products of the Hanyang works:

	Tayeh Hematite %	Tayeh Brown Iron Ore %	Magnetite %
Fe	62.00	48.00	65.00
Mn	0.30	7.00	0.13
SiO_2	4.00	6.00	3.00
Al_2O_3	2.00	.....	.....
S	0.02	0.01	0.06
P	0.05	0.03	0.12

Tayeh limestone, 96% $CaCO_3$, 2.5 SiO_2.

Hanyang Blast-Furnace Slag %		Foundry Pig Iron %		Siemens-Martins Pig Iron. %	
SiO_2	33.0	C	3.80	C	3.90
Al_2O_3	16.0	Si	2.50	Si	0.65
CaO	46.0	Mn	1.00	Mn	1.10
MgO	2.0	S	0.01	S	0.045
Fe	1.0	P	0.20	P	0.25
Mn	0.6				

Samples of Martin steel:

	First Sample %	Finished Steel %
C	3.340	0.400
Si	.....	0.085
Mn	0.260	0.089
P	0.240	0.055
S	0.045	0.028

The percentage of carbon in the second sample was 0.64; in the third, 0.50; fourth, 0.46; fifth, 0.44; sixth, 0.42; seventh, 0.27; eighth, 0.26; ninth, 0.22; tenth, 0.30; and in the finished steel 0.40.

Analyses of other samples of steel gave:

	Per Cent.	Per Cent.
Si	0.095	0.079
Mn	0.790	0.900
C	0.330	0.470
P	0.058	0.065
S	0.025	0.035

Rail and bolt tests made for the Peking & Hankow railroad gave the following results:

85-lb. Rails.			Strength of Bolts.		
Strength	61 kg.	69 kg.			
Tensile strength	37.3 kg.		39.0 kg.	38.0	38.5
Elongation	17.5%	15.0%	27.0	29.0	30.0%
Elastic limit	35.0 kg.	35.0 kg.	28.8 kg.	27.0	27.5 kg.
Contraction	39.0%	36.0%	63.0%	62.0%	60.0%

Since the Hanyang Iron & Steel Works is the only one in the whole of China, that is making steel, a few words concerning it may be of interest. The company owns the Tayeh mines and the Pinghsiang collieries. This plant was built by one of the Viceroys, in the early '80s, and at first made only pig-iron, for local use. The Government attempted to produce steel, but being unsuccessful and also failing to keep the works on a paying basis, they abandoned the attempt and, in 1893, the plant passed into the hands of Chinese capitalists. Mining engineers and metallurgists were engaged from Belgium and France, the plant was re-modeled and partly re-built, Siemens-Martins open-hearth steel-furnaces were installed and the plant, thus re-modeled, began producing steel in 1894.

At present there are two 125-ton blast-furnaces in operation, four 30-ton Siemens-Martins steel-furnaces, a 100-cm. blooming mill, a 75-cm. reversing rail-rolling mill, and straightening and truing machinery. His excellency, V. K. Lee, is the general manager, but all of the engineers, metallurgists, and heads of departments, are either Germans or Frenchmen. The lesser foremen and contractors are Chinese. The thing that impresses one most, on entering the works, is the almost swarming mass of native workers, surrounding every operation and it is next to impossible to understand why they are not burned, scalded, crushed, and killed by the score. Each operation requires from eight to twelve times as many men as one is accustomed to seeing in a similar works in the West.

The company is just at present completing a most excellent modern German blast-furnace, of the latest design, and intend blowing it in this spring. It will have a capacity of over 250 tons per day, is 32 metres high, the diameter of the crucible is 3.15 metres, and there are 16 tuyeres, 8 to be used at a time, the other 8 being held in reserve. The interesting thing about this furnace is the method of cooling it. Small cast-iron pans 45 cm. long, 42 wide, and 11 deep, are set into the brick-work, around the outer circumference, giving the outer circumference the appearance of almost a net-work of these pans from the tuyeres to within three metres of the top of the furnace. The pans are placed in hodizontal rows around the circumference. The rows are 75 cm. apart, and the horizontal distance between pans is 100 cm.; the pans are so arranged that each in a row is not directly under a pan of the row next higher, but the space is so divided as to expose as little of the brick-work as possible. A slit or open space is left in the outside end of the pans and through this a 3-cm. iron pipe passes, to supply cooling water. Another similar pipe leads out of the bottom of the pan at the other side and delivers the water to the next lower pan, and so on through the system. The water is kept in circulation throughout this net-work of pans. When the water has traveled through four pans, it is conducted to troughs which pass around the circumference and is taken out of the system.

To give an idea of the slowness of construction in China, it might be mentioned that it has required three years to construct this furnace. There are many interesting incidents and illustrations of the intense superstition of the Chinese people, which might be related in connection with this plant, but as the purpose of this article was to be a brief description of the Tayeh mines, I am compelled to omit them.

It might be interesting to add that several large shipments of pig iron from the Hanyang works have gone to New York. In November, 50,000 metric tons started for America, and another shipment was made about six months previous. This company is able to lay pig iron down in New York, for less than the price quoted in Pittsburg. Shipment of Chinese pig-iron to Pacific Coast ports is not unusual. This works has a bright future, and present plans call for extensive improvements. Doubtless Tayeh iron is destined to be widely known.

HALF DOME OF THE YOSEMITE VALLEY

By F. E. Matthes.

* The Half Dome, like the other domes of the Yosemite region, represents a huge granite monolith that has survived the reduction of the more fissile rocks about it by virtue of the superior resistance to disintegration offered by its undivided mass. It is unique in that its dome form is a partial or incomplete one, being abruptly trenched on the northwest by a straight and sheer cliff face 2000 ft. high. The curving back and sides are entirely normal, having evidently evolved through progressive exfoliation, like the bulbous exteriors of all domes. Their smooth sweeping curves are indicative of maturity; for it is only through long continued shelling that a monolith of irregular shape is reduced to a continuously rounded mass. At the same time, the prevailing flatness of the back and its trend, parallel with the northeast-southwest system of joints, prominent throughout the region, are clearly inherited from the structure planes that originally bounded the monolith on that side.

For the origin of the sheer front of the dome, three hypotheses have been advanced: (1) The present mass is a true half dome—that is, a remnant of a much larger monolith, the other portion of which has caved off, perhaps owing to glacial undercutting in the Tenaya trough. (2) The monolith extended originally but little farther to the northwest, and has suffered reduction on that side, as on the other sides, merely through normal exfoliation. Only, the shells on the northwest side were plane instead of curved, because the initial bounding surface was plane. (3) The present front coincides essentially with the plane fissure that from the first constituted the boundary of the monolith, and has only comparatively recently been exposed through the rapid scaling off of the thin plates of a zone of vertically sheeted rock.

The first hypothesis seems at once to be inadmissible, inasmuch as massive granites inherently break off by conchoidal fractures and not by plane fractures of the magnitude of the dome front. The hypothesis must therefore be rejected.

The second finds some support in the overhanging shells on the top of the dome, for these plainly indicate the former extension of the monolith for a short distance to the northwest. The existence, however, of a great mass of plates clinging to the northeast end of the cliff face in the form of a conspicuous shoulder, together with the strongly accentuated fracture that separates them from the body of the monolith proper, is held to demonstrate conclusively that the monolith never did extend beyond its present front, but was actually bounded there by a zone of thinly sheeted rock. Only toward the top of the front has exfoliation set in and commenced its rounding off process (under the overhang), as is patent from the profile view of the dome obtained from the Quarter Domes.

* Read before the Washington Geological Society and abstracted from *Science*.

Electrical Reduction of Iron

By Joseph W. Richards

*Electrical reduction of iron ore is a topic, one which a few years ago could only have been discussed in a speculative manner, and by one with the prophetic gift highly developed. The reduction of iron ore by means of the energy of fuel, in blast-furnaces, is constructed on such a stupendous scale, and with such great economy, that the blast-furnace has been frequently called our most perfect furnace, and the possibility of electrical energy taking any part in this industry appeared visionary. When electric furnaces were first developed on a commercial scale, it was generally admitted that if they entered the iron industry at all their best chance was in the production of highly expensive special quality steels, costing $500 to $1000 per ton, and that their poorest chance would be to compete in the manufacture of pig-iron costing $10 to $15 per ton. Yet inside of five years, those who have watched the development of the electrical iron and steel industry have seen small furnaces turning out fine steels succeeded by larger ones successfully manufacturing common steels, such as steel-castings and rail-steel, and finally the operation of a larger electric shaft-furnace manufacturing pig-iron on a commercial scale.

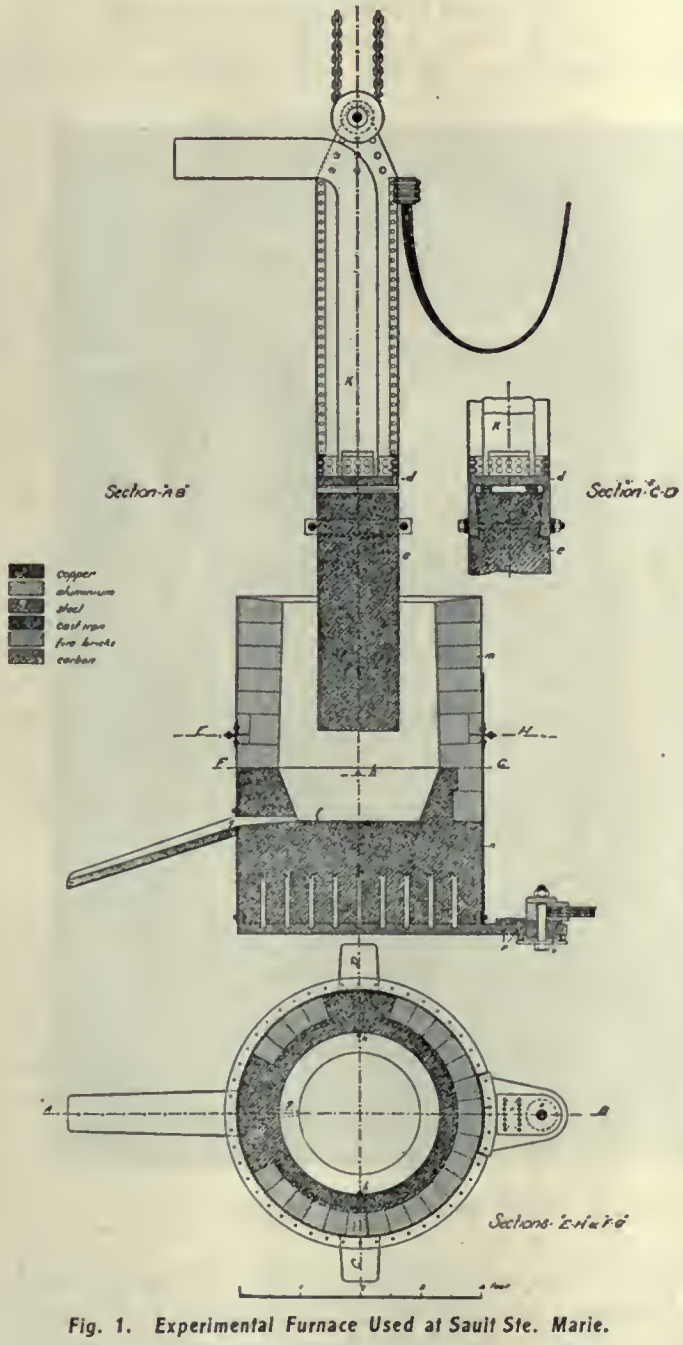

Fig. 1. Experimental Furnace Used at Sault Ste. Marie.

Most of the credit for the recent advances in the electrical production of pig-iron should be given to the far-sighted interest of the Canadian Government in this subject, principally, under the influence of its active Director of the Department of Mines, Eugene Haanel, of Ottawa, and to the enterprising Swedes, principally Assar Grönwall, Axel Lindblad, and Otto Stalhane, who have founded the company 'Aktiebolaget Electrometall', of Ludvika, Sweden. If to these we add the names of H. H. Noble, of the Northern California Power Co., and his able assistant, D. A. Lyon, who have constructed and operated an electric pig-iron furnace in Shasta county, California, the list of active workers in this field is nearly complete.

When, in January, 1904, the Canadian Government sent a commission, under Dr. Haanel, "to investigate the different electro-thermic processes for the smelting of iron ores and the making of steel, in operation in Europe," the commission found and reported upon a number of different electric steel furnaces in commercial operation, but found not a single electric pig-iron furnace at work. From the voluminous and valuable report of this commission (published by the Canadian Government, August, 1904), it is stated that several of the European works were persuaded to make experiments on the production of pig-iron. Some of these tests are described briefly in the following extracts from the report: At La Praz, France, Mr. Héroult was good enough to make some experiments in smelting iron ores. The furnace employed was exceedingly simple. These experiments were made by Mr. Héroult for the purpose of demonstrating the simplicity of the process of reducing iron ores by the electric process, and it was not intended to demonstrate a figure of cost per ton of pig-iron produced by this process. It appears from the data given that this test was crude and poorly arranged. Too little carbon for reduction was used in the charge, the furnace was run too cold, and the power-consumption ran up to 0.525 hp. per year per ton of pig-iron obtained.

At Livet, France, the works of Keller-Leleux et Cie., possessed furnaces constructed for the reduction of ore, and used for manufacturing ferro-silicon and ferro-chromium. These were placed at the disposal of the commission, and two long runs were made of 55 and 48 hr. each, with all the data carefully controlled and checked. The complete details of these runs, with illustrations of the furnace used, can be found in the report of the commission. It is of the resistance-type, with two shafts, each with its vertical electrode embedded in the charge, and connected by a well in which metal and slag collect. The current passes from the electrodes to carbon blocks embedded in the base of the furnace. The lining was a rammed-in mixture of dolomite and tar, similar to

* From the *Journal* of the Franklin Institute.

that of a basic-lined bessemer converter. The electrodes were square, 280 mm. (11 in.) on the side and 1400 mm. (56 in.) long. The 55-hr. run was interrupted to put in a watt-meter, and the metal set in the furnace, so that the power-consumption for this run, 0.52 hp. year per metric ton of pig-iron, was abnormal. In the second run of 48 hr. no interruption occurred, the furnace "working quietly, and without the slightest accident; the gases discharging on top in flickering flames, showing that the gas resulting from the reduction of the ore escaped at a low pressure. The workmen were ordinary Italian laborers, without any special training." This second run was successful in producing, at will, different classes of pig-iron, gray, white, and mottled, and in setting a definite figure for the amount of electric energy required per ton of pig-iron produced. The furnace was nominally of 300 hp. capacity, but running with 350 hp.; it consumed 0.25 hp. year per metric ton of pig-iron produced, using 41% of fuel. This is a satisfactory figure, and is partly attributable to running the furnace hard, that is, above capacity.

On the return of the Canadian Commission from Europe, and the publication of its report, the Canadian Government placed at the disposal of Dr. Haanel and his staff $15,000 for investigating the suitability of the electric process for reducing Canadian iron ores. The experiments were carried out early in 1906, and may be found recorded in detail in the report published in February, 1907, by the Mines Branch, Department of the Interior, at Ottawa. An analytical discussion of these experiments, and the results obtained, was later presented by myself to the American Electrochemical Society at its meeting in New York City, October 18, 1907, and published in the Transactions of that Society, vol. xii, p. 81. The furnace used is shown in Fig. 1. The following conclusions from the author's analysis may here suffice: (1) Too much carbon was used in every case, not allowing a good utilization of the heat of oxidation of carbon in the furnace. A smaller proportion of carbon, more perfectly consumed to CO_2, would have generated more heat and thus have helped the furnace more. (2) The electric current furnished about two-thirds of the energy required for all purposes, the carbon one-third. (3) The consumption of fixed carbon was 24 to 38% of the weight of pig-iron, giving ratios of CO to CO_2 in the gases of 4.5 up to 9, by volume, whereas a ratio of 1 is possible, would require far less carbon, and would produce more heat in the furnace. For the details of this analysis reference is made to the original paper. One thing is particularly worth noting, the Sault Ste. Marie furnace was small and was worked hard, a condition favorable for small conduction and radiation loss, and economy of power.

The experiments at Sault Ste. Marie bore fruit first in Sweden, by inciting experimenters there to construct a large electric shaft furnace for the regular commercial production of pig-iron. Messrs. Grönwall, Lindblad, and Stalhane, conducted preliminary experiments at Ludvika, Sweden, in the summer of 1907, with a small furnace of 300-hp. capacity; in the summer of 1908 a larger furnace of different type was constructed, and in the autumn of 1908 a still larger furnace, embodying the results of all their experience, was completed. This furnace was designed for 1500 kilowatts, and may be truly termed the pioneer electric pig-iron furnace. The best description of this furnace and its working are to be found in a paper by Dr. E. Haanel in the Transactions of the American Electrochemical Society, vol. xv, p. 25, and in the subsequent report of Dr. Haanel published by the Canadian Department of Mines, in October, 1909, entitled 'Investigation of an Electric Shaft-Furnace at Domnarfvet, Sweden'. The following details and illustrations (Fig. 2 and 3), are taken from Dr. Haanel's publications: The total height above the ground-level is 25 ft.; the crucible is 7 ft. high, the shaft, 18. The entire weight of the upper shaft

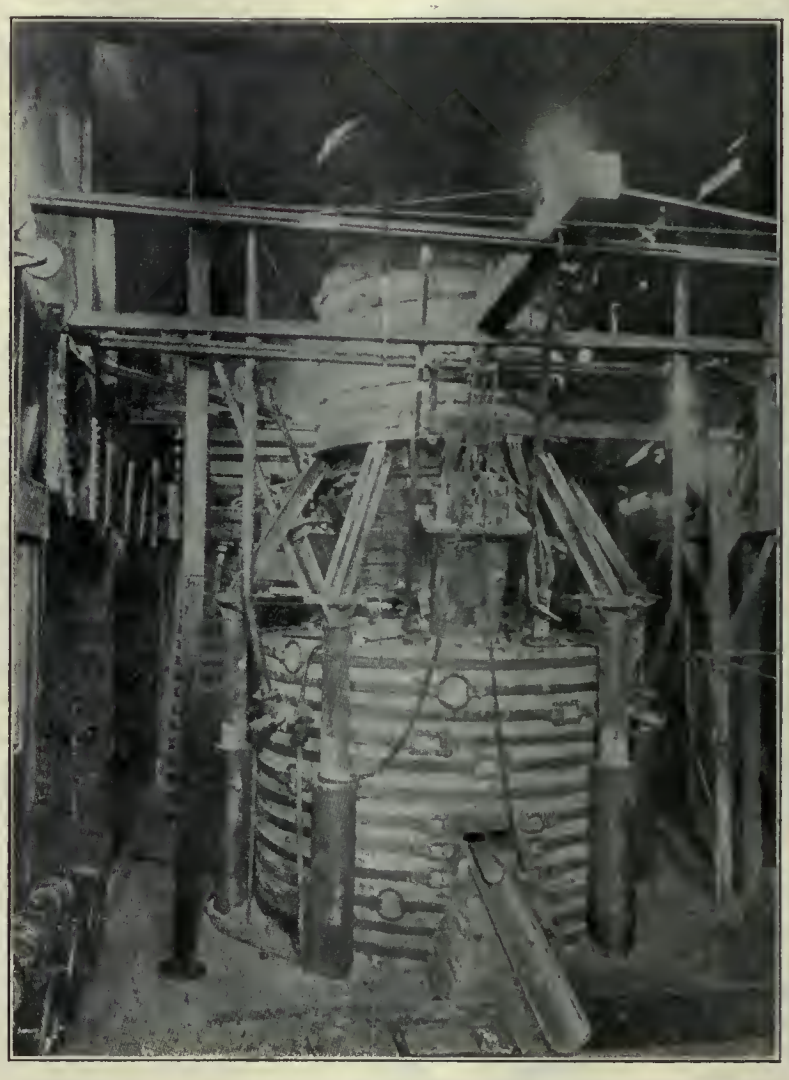

Fig. 2. Electric Furnace at Ludvika, Sweden.

is carried on 6 cast-iron columns; none of it rests on the arch covering the crucible. This arched roof has openings for the three electrodes, each composed of two carbons 11 in. square by 63 in. long, making each electrode 11 by 22 by 63 in. The electrode holder is a steel frame into which the electrodes are fastened by copper wedges. The electrodes pass through water-cooled stuffing boxes. The crucible is lined with magnesite-brick, a material never found usable in blast-furnaces. Some of the escaping furnace-gas is pumped back by means of a fan into the free space under the crucible arch, for the purpose of cooling off that arch and so preserving it from the intense radiated heat. The electric current is supplied as 3-phase current to the three electrodes by three transformers of 500 kilo-volt-amperes each, transforming the current down to $^1/_{14}$ its primary voltage, and capable of regulation between 20 and 85 volts. The especially novel features are the arch over the crucible, the projecting downward of the electrodes through this arch into contact with the charge as it spreads out from the central shaft into the crucible, the magnesia lining, and the return of part of the throat-gases into the crucible under the arched roof. It can readily be seen that a large amount of thought and experience are embodied in the details of this furnace.

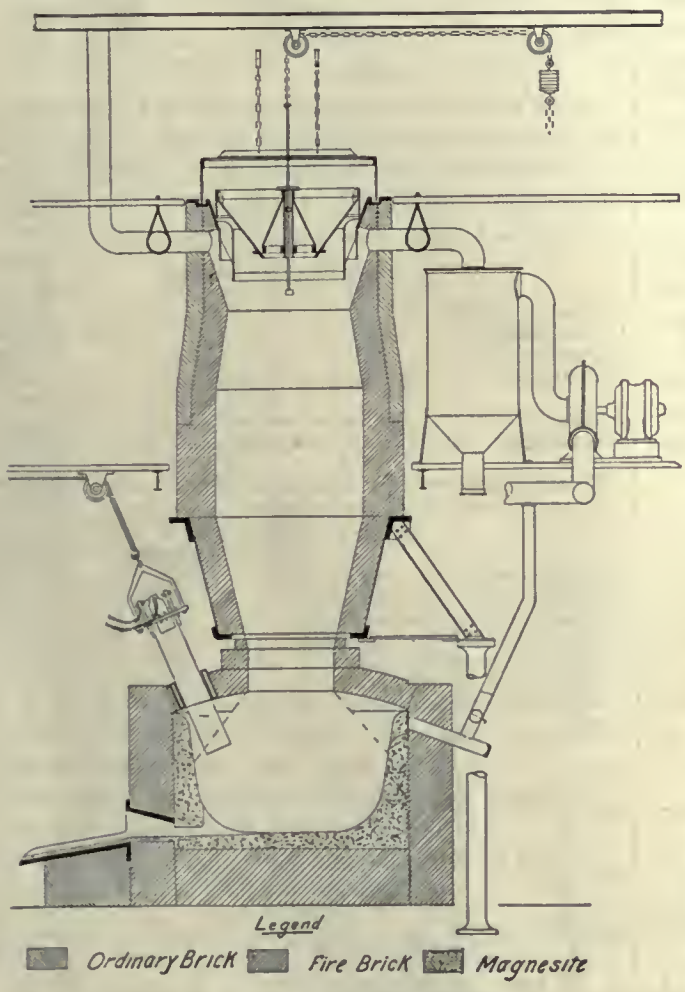

Fig. 3. Section of Ludvika Furnace.

A trial run was made under Dr. Haanel's inspection, starting with the cold furnace. Besides the handicap of starting cold, and with all the masonry fresh, the furnace was insufficiently supplied with power. Instead of the 1500 kw. which it was designed for, only about 400 could be gotten. Under these circumstances, the losses of heat by radiation and conduction were probably almost as great intrinsically as they would have been with full power, which means that they were relatively or proportionately, to the energy used, probably three or four times as great. The result of the test is, therefore, far from indicating the maximum commercial efficiency of this furnace.

In spite of these adverse conditions, pig-iron was made from the ore at the rate of 0.40 electric horse-power year consumed per metric ton of pig-iron. The fuel consumed for reduction was 27.5 kg. of coke per 100 of pig-iron, and of electrodes 5 kg. It is altogether reasonable to assume that the power-consumption, when in regular running, will not exceed 0.3 electric horse-power year, and on this basis, counting power at $12 per electric horse-power year and charcoal (83% carbon) at $8 per metric ton (2204 lb.), Professor Odelstjerna, of Stockholm, has estimated that pig-iron can now be made in Sweden in this furnace at $1.50 per ton less than in Swedish blast-furnaces. It is my opinion that this furnace, if run at 3000 kw., could make pig-iron at 0.2 electric horse-power year per ton of output, making a further saving of $1.20 per ton. With a prospective saving of $2.50 per ton, the Swedish blast-furnace industry stands a good chance of being superseded by the electric furnace, as soon as the latter gets into proper working order.

The accompanying diagrams are intended to illustrate the fundamental principles of electric furnace-reduction of iron ore. They are entirely dependent upon the rate at which the furnace is run and the proportion of CO to CO_2 in the gases. In the latter respect, a proportion of 1 to 1 by volume is entirely practicable and should be attained in electric smelting, although 2 to 1 is the usual ratio in blast-furnace practice. A kilogram of oxygen burning carbon to CO gives up 1820 heat units, but if burn-

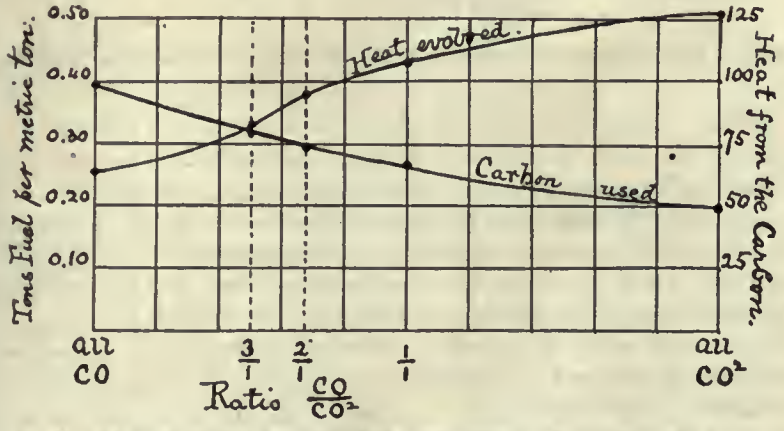

Fig. 4. Variation of Fuel Required, With Composition of Waste Gases Produced.

ing only half as much carbon to CO_2 it gives up 3075 calories. Since there is a definite amount of oxygen to be removed per ton of pig-iron made, more assistance is obtained from the combination of carbon and oxygen the more CO_2 and the less CO is formed. Fig. 4 shows the heat evolved, in units of 1000 calories, as the ratio of CO to CO_2 varies from all CO to ratios of CO to $CO_2 = 3$, 2, and 1, and extended to the supposed case of all CO_2 being formed. It shows graphically the fact that the smaller the amount of carbon used the more heat is obtained from its oxidation, because it is being burnt by a fixed quantity of oxygen.

Experiments on the reduction of iron oxides in currents of CO gas render it improbable that a lower ratio of CO to CO_2 than 1 to 1 can be obtained in practice, even under the most favorable electric furnace conditions. This corresponds to 0.26 ton of carbon per ton of pig-iron made, and a thermal assistance from the carbon of 1,111,500 calories (1750 horse-power-hours) per ton of iron.

Fig. 5 shows the variation of horse-power required per ton of pig-iron with the ratios of CO to CO_2 in the gases. It shows distinctly how wasteful of power it is to run a furnace with too much carbon. With a certain amount of carbon charged it is practically impossible to utilize it except it burns mostly to CO, and then the high power-consumption is the result of the lack of proper thermal assistance from the

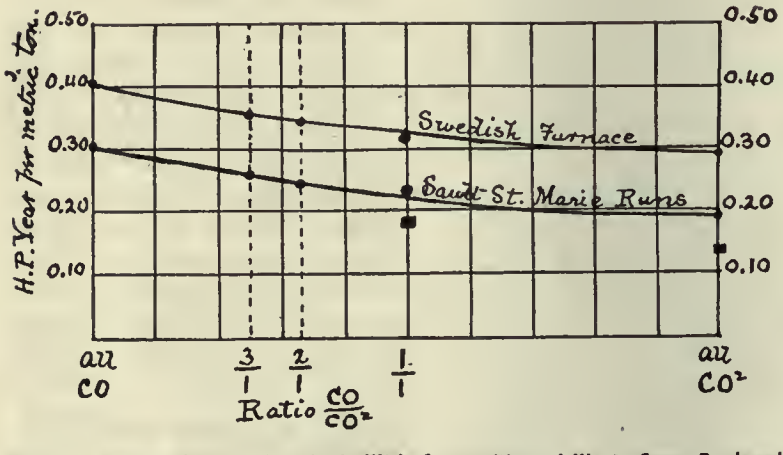

Fig. 5 Variation of Power Required, With Composition of Waste Gases Produced.

carbon. The power-curve of the Swedish furnace is above those of the Sault Ste. Marie runs, for the same fuel-consumption or ratio of CO to CO_2, because the former furnace was being run at not over one-fourth, possibly nearer one-sixth, of its proper power-supply, while the latter furnace was small and was pushed hard. The difference of 0.1 hp. year per ton of pig-iron made is probably entirely ascribable to high radiation and to conduction losses, due to the relatively slow running.

Dr. Haanel gives sufficient data for forming a good idea of the heat distribution in the large Swedish furnace, the charges being, ore, 220; coke, 37.4; lime, 4.4. The data are as follows:

ORE	Per Cent.
Fe	62.96

COKE	Per Cent.
S	0.55
C	85.00
Ash	14.45

SLAG			
SiO_2	26.54	CaO	54.48
S	0.78	Fe	0.35

PIG-IRON			
Fe	94.485	C	3.20
Si	0.075	Mn	0.33
P	1.900	S	0.01

GASES	Vol. %
CO_2	25.00
Co	65.00
H	10.00

From the above data it can be calculated, assuming the gases escaping at 250°C. and the pig-iron and slag at a little above the blast-furnace temperature, that the energy received and distributed by the furnace is about as follows, per 100 kg. of pig-iron:

HEAT DEVELOPED	Calories.
Carbon oxidized to CO	52,318
CO oxidized to CO_2	44,785
Formation of slag	2,058
Carburization of iron	2,256
Total heat of chemical reactions—31%	101,417
Heat energy of 0.041 e.h.p. year—69%	223,171
Total available energy	324,588
Average required in blast-furnaces	400,000

HEAT DISTRIBUTION	Calories.	Per Cent.
Reduction of iron oxide	155,221	48.00
Reduction of other oxides	10,174	3.50
Evaporation of water	1,025	0.30
Sensible heat in waste-gases	4,075	1.30
Sensible heat in pig-iron	32,500	10.00
Sensible heat in slag	8,600	2.70
Radiat'n and conduct'n loss (diff.)	112,850	33.20

The last item of the above schedule is much larger than it should be. Some modern blast-furnaces run with one-tenth that much. The trouble with this furnace was that it was run only about one-tenth as fast as it should be for heat economy. If it be assumed that this furnace is run fast and carefully, so as to get a ratio of CO to CO_2 in the gases of 1 to 1, it can be estimated what will be the probable running of a large electric pig-iron furnace, such as will undoubtedly be in steady operation in the near future. The requirement for power will be that necessary to furnish the needed heat, less that furnished by the chemical reactions.

These will be, per ton of pig-iron produced:

HEAT AND POWER REQUIREMENTS	Calories.	Horse-power Hours.
Needed for reductions	1,655,000	2600
Sensible heat of pig-iron	300,000	470
Sensible heat of slag	60,000	100
Radiation and conduction	100,000	160
Total	2,115,000	3330
Furnished by chemical reactions	1,111,500	1750
Needed from electric current	1,003,500	1580

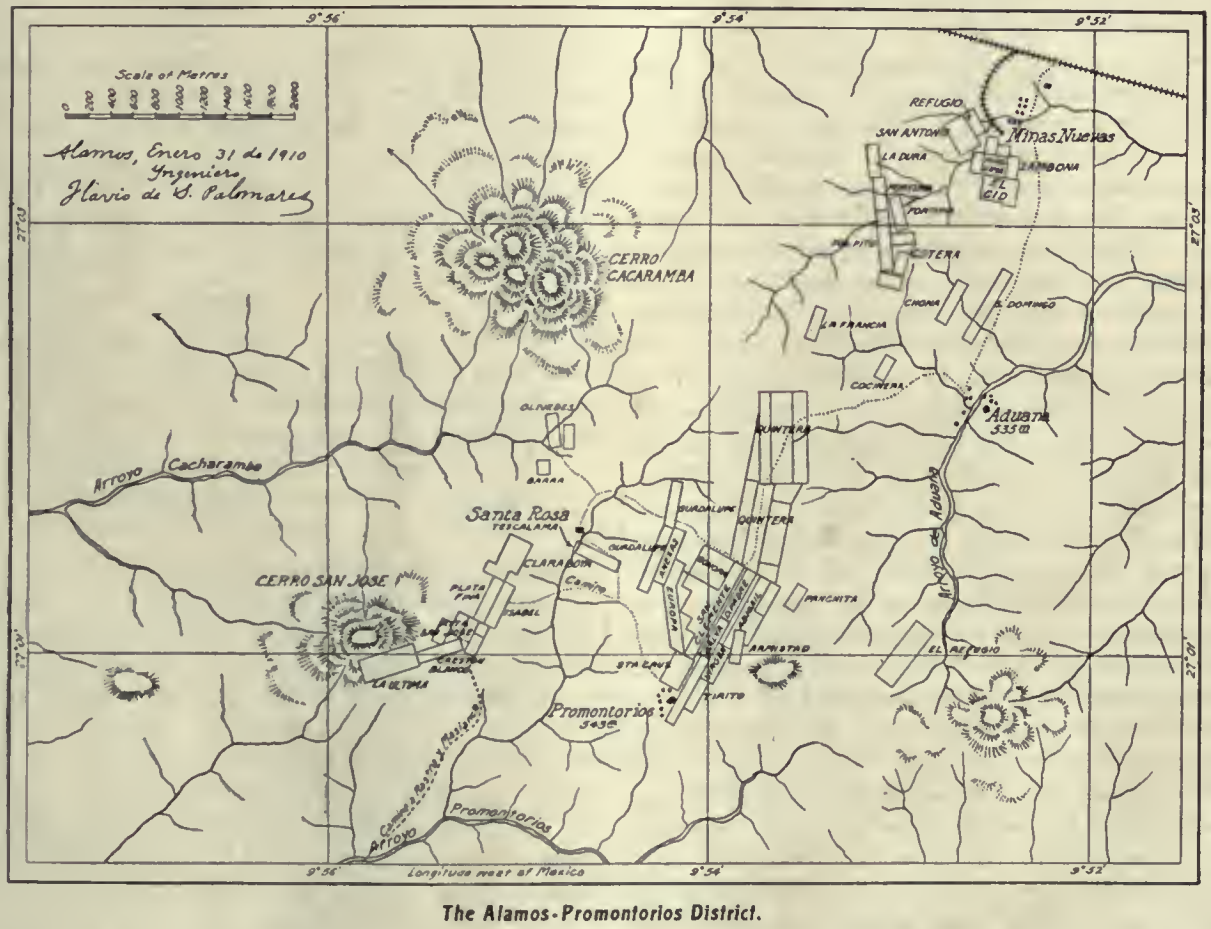
The following is therefore the conclusion of this investigation: If a larger electric shaft-furnace is run rapidly, with abundant power, and the gases escaping contain at least as much CO_2 by volume as CO, the minimum power-requirement which will be approximated is 1580 hp.-hours, or 0.18 hp.-years, per metric ton (2204 lb.) of pig-iron produced. One ton per 0.226 hp.-year has already been reached in an experimental run.

Alamos-Promonitos District

Written for the MINING AND SCIENTIFIC PRESS
By T. P. BRINEGAR

The mines which constitute this group are on the mineral zone which crosses the Alamos mountains about seven miles west of Alamos, Sonora, Mexico. The heart of the zone lies within a rectangular surface 1½ miles wide by 4 long, which commences at the Zambona mine, near Minas Nuevas, on the northeast, and extends southwest to include the Old Promontorio and San José mines. Precious metals were discovered in this region early in the eighteenth century, and the quantities yielded by this group alone have exceeded $100,000,000 in value. According to Gamboa's 'Treatise on Mining', one remittance, in 1799 under charge of Alvarez, amounted to more than 1600 bars of silver. Humboldt noted in his records, 1808, that he "passed a train of one thousand mules loaded with bars of silver from these mines on their way to the City of Mexico." The production became so great that the Government was induced to establish a mint in Alamos for the special purpose of coining the metals produced at this point.

The geological formation is clearly revealed. The basal rock of the region is granite which has been disturbed by powerful deep-seated forces. From these earth-disturbances originated two well defined fissure-zones. The uplift of the earth-crust on the southeast formed the Alamos mountains, and its subsidence on the northwest resulted in many irregular folds, which were covered by extensive volcanic eruptives, chiefly of an andesitic type. In turn this was covered by sediments, the larger part being limestone. The conditions were favorable for erosion, which reduced the elevation several thousand feet. The fissure-zones, under present surface conditions, are about 5000 ft. apart, striking in a northeast direction. Both have granite 'floors' or footwalls, and dip toward each other. Between them is a 'core' of andesite porphyry which forms the hanging wall of each vein-zone. This core was the centre of subsequent dynamic activity, shown by the evidences of upheavals and the rearranged condition of the strata. In it are found many igneous dikes. Constant movements between the walls of the fissure-zones served to keep them open to the free circulation of mineral-bearing solutions. Cerra Cacharamba, a volcanic 'neck' 3700 ft. above sea-level, is the land-mark of the district, and Humboldt during his visit to the camp in 1808, wrote figuratively that, "Cacharamba rests on a bed of silver." It seems that the past hundred years of mining near its base has demonstrated that the great scientist was not far amiss in his rhetoric.



The Alamos-Promontorios District.

The fissure-zones have been designated as east and west contacts. The east contact is the 'mother lode' of the zone, and is generally known as the Promontorio-Quintera vein. The names of the productive mines situated on the several big ore-shoots of the vein are, Old Promontorios, Quintera, Santo Domingo, and Zambona. The Púlpito on the north and the Nueva Promontorio on the south are new properties in course of development and which have mineralized veins that promise future productiveness. Generally, mixed ores are extracted from mines on the east contact, which are found in the form of

oxides near the surface and turn into rich sulphides in depth. Some of the ore-shoots are over 700 ft. long, and in many places over 40 ft. wide. Gray copper is the principal ore from this lode, and its fabulous quantities and high silver content are almost unparalleled in the annals of mining. These mines are owned by different companies, each of which has more 'likely' ground than it will explore in a score of years.

The west contact is best known as the San José-Claraboya vein. Through the past two centuries it has remained comparatively unexplored. The Mineral de Santa Rosa (Claraboya) is said to be the oldest in the camp, and from the large drill-holes found in the old *tajos* (open-cuts), one can give credence to the tradition that "it was the rich mine of the early fathers." The San José-Claraboya is a well defined vein of creamy to reddish-brown quartz, as shown in the workings on the lower levels of the two mines of the same names. In the upper workings or shear-zone, the vein branches into seven parts, all of which unite in depth forming a body about 40 ft. wide. The groups of mines which have been under process of development during the past year are: Claraboya, San José, San Clemente, and Plata-Fina. El Ultimo, Barra, and Olvidos are held as important prospects. The ores from the mines on the west contact yield native silver, oxides, and gold. They are very docile, and readily yield to simple economic treatment. The assay values range from 15 to 5000 oz. silver and up to $70 in gold. The old dumps of the Claraboya have been very profitable to the owner who has been reworking them during the past two years. He is developing the mine with an adit which is giving good results. The San José is regarded as the 'mascot' of the camp. It was bought by G. W. Du Bes about a year ago, since which time he has been developing and shipping ore, and erecting machinery. The Plata-Fina is between the San José and Claraboya, adjoining them. It is being developed by a shaft on the junction of the several veins. The San Clemente is owned by Rafael Ibarra, president of the town of Promontorios. The ore extracted more than pays expenses, and the owner regards it as the best prospect he has ever owned. These new workings, along with the Púlpito and Nueva Promontorio on the east contact, go to show what great possibilities await the judicious investment of capital along these two great fissure-veins. Side by side with these great mines are many undeveloped prospects that, judged by surface indications, warrant exploration.

The district possesses favorable economic conditions for mine operations. The altitude averages about 2000 ft. above sea-level, and gives a climate, modified by the gulf-breezes, that is as healthy as any place on the Pacific Coast. Water is abundant and of the best quality. The west part of the zone has access to the wooded hills to the southwest where such fuel is cheap. The transportation facilities are now good, as the recent completion of the Southern Pacific Railroad of Mexico affords an outlet from Minas Nuevas, and good wagon-roads lead to Masiaca, also on the railroad, and to the nearby seaport of Agiabampo. The cost of living and freighting is low.

Carbon and Cellulose in Cyanide Solutions

By A. J. Clark and W. J. Sharwood

*These notes contain the results of a series of experiments and observations made by the authors at the Homestake mine, Lead, South Dakota, together with information on the subject gathered from various sources.

Two sets of experiments were made on the precipitating effect on gold-bearing solutions of various precipitating substances, with the results tabulated below under series A and B. In each experiment 300 c.c. of solution was taken. In series A, 5 gm. of the precipitant was added; the mixture was stirred vigorously for a moment and filtered, with further agitation each time the funnel was refilled with the liquid. After filtration the filtrate was passed through the filter again, being thus exposed to the sediment retained by the filter a second time. In series B the conditions were the same as in A except that a larger quantity of precipitant (which was not weighed, but was at least 20 gm.) was taken, and there was only a single passage through the filter.

Series.	Precipitant.	Original Assay of Solution.	Assay of Filtrate.	Gold Precipitated.
				%
A	Graphite (Dixon's flake)	$2.63	$2.65	0.0
	Bituminous coal (40 mesh)	"	2.45	7.0
	Coke (40 mesh)	"	2.11	19.6
	Charcoal (pine, 40 mesh)	"	1.92	27.0
	Calcium carbide	"	2.50	5.0
	Zinc dust	"	0.02	99.3
B	Graphite	2.73	2.73	0.0
	Coal	"	2.13	22.0

Repeated tests have shown similar results. Pure graphite, whatever its source, seems to be entirely without effect on the gold in cyanide solutions, and anthracite coal nearly so. The semi-bituminous or sub-bituminous coals of the Western United States have a feeble precipitating action. Well burned coke is fairly effective and charcoal much more so. Lubricants containing graphite with mineral oil, intended for use in rock drills, and the clean graphite extracted from them, are entirely without effect after several hours' contact with solution. Either a sufficiently long contact with, or a slow percolation through, a relatively large amount of bituminous coal, removed as much in some cases as 99% of the gold in a cyanide solution, but the efficiency of the coal as a precipitant fell off with repeated use, as is the case with charcoal.

Experiments on the effect of wood ashes containing a small proportion of charcoal on the cyanide extraction of gold from tailing containing pyrite were made in percolators upon pyritous tailing, to which various proportions of ashes were added, together with a suitable amount of lime (about 5 lb. per ton), the charges being thoroughly mixed. The cyanide solution was in actual contact with the charges four days, but the charges were drained dry once during the treatment, as well as at the conclusion. The tailing assayed about $1.75 in gold per ton, and upon

*Abstract from Trans. Chem., Met., & Min. Soc. of South Africa.

it, under normal conditions, without the presence of wood ashes, an extraction of at least from 70 to 75% would have been obtained. The results of the experiments were as follows:

Ashes Added to Tailing	Gold Extracted by Cyanide
%	%
0.17	52.8
9.8	46.0
1.73	35.8
8.0	3.5

At the Homestake cyanide plants, when similar ashes or charcoal have been inadvertently introduced into the treatment vats, a very small percentage has been found to lower the gold extraction from 70 to 75% to less than 60. As to the origin of these ashes, in one case it had been traced to an old stope, into which they had been dumped from the surface some years before; in another case charcoal had been produced by the charring of timbers in a former mine fire, and had become mixed with the ore treated. Sometimes charcoal and cinders have been introduced into the plants by the dumping into the mill launder of ashes from a heating stove; at other times accumulations of ashes and clinker, produced by the burning of chips (collected from the mortars), had been run through the batteries.

Some years ago heavy losses were reported in the cyaniding of ore at an Australian mine, at which crushing and amalgamation were facilitated by heating the ore by burning it like limestone in a furnace with alternate layers of cordwood, and quenching the heated ore with water. A similar kiln treatment has been used successfully at some small California mines, rendering refractory ore containing pyrite and tellurides more amenable both to crushing and amalgamation in an arrastre, but it seems to have proved fatal to cyaniding in the former instance, probably owing to the presence of charcoal. Park ('The Cyanide Process', 1897 ed.) states that in New Zealand it was found advisable to hand-pick charcoal from dried ore prior to crushing and cyaniding.

Several instances have been reported where 'graphitic' ore (usually slate or schist) has caused re-precipitation. Most likely this is due to the fact that the carbon in such carbonaceous schists is often far from being completely converted into graphite, and may exist largely in the form of hydrocarbons, in a condition similar to that of partly burned coal or wood.

Some floating rubbish, consisting of charcoal and charred pieces of wood, as well as some clean chips and twigs which came from a settling dam and creek bed, and particles of coke which came from the smoke-stacks of the locomotive and steam-shovel, was skimmed from the surface of the cyanide solution in a slime agitator vat. The solution contained approximately: gold, 0.023 oz. per ton (47c.); silver, 0.28 oz. per ton (14c.); and potassium cyanide, 0.025%. The skimmed rubbish was rinsed twice with water, and dried at 100°C. It was then divided into two portions, one containing the charcoal and charred wood and the other the clean chips and twigs. The two portions were then weighed, some of each being burned in clean roasting-dishes in a muffle. The substances were assayed before and after burning, with the results tabulated below.

As neither of the two classes of material contained more than its own weight of solution, when removed from the vat, obviously a considerable precipitation had occurred in proportion to the weight of the material; the coke, charcoal, and other material precipitating the gold content of approximately 100 times their weight of solution, and the twigs precipitating 10 times their weight, the corresponding amounts for the silver content being 27 and 10 respectively. In reply to a suggestion by W. A. Caldecott that these chips, and the like, might have been partly burned or charred, it may be stated that they were to all appearance unaltered. It is possible, however, that some of them had been in the dam or creek for months, or even for several years, so that actual decay may have commenced.

Number.	Material.	Proportion of Total Weight of Original Sample.	Ounces per Ton.		Value per Ton.		
			Gold.	Silver.	Gold.	Silver.	Total.
1	Coke, charcoal, and charred wood	40%	2.25	7.50	$45.27	$3.75	$49.02
2	Ash of same	¼ (or 25% of total ash)	18.00	60.00	365.40	30.00	395.40
3	Clean chips and twigs	60%	0.24	2.70	4.87	1.35	6.22
4	Ash of same	¾ (or 75% of total ash)	0.96	10.80	19.48	5.40	24.88

That decaying wood is an active precipitant for gold in cyanide solution was evident from a series of samples taken from a residue dam, the sand discharged into which contained appreciable amounts of solution as well as traces of dissolved gold, so that the aeration consequent on discharging no doubt resulted in the dissolution of a little more gold. While the average assay value of the sand was lower than that of the residue as discharged, the lower strata were slightly higher in gold content, as might be expected from the leaching that had since taken place. At two points, however, a decided concentration was noted. One of these was found to be in the neighborhood of a pine post, and another around the decaying stump of a tree that had been killed by the residue. Mr. Caldecott's suggestion that the effect of the wood fibre itself is practically nothing, and that apparent precipitation by wood is due merely to absorption of solution, is confirmed by our next series of determinations.

Several writers have published experimental results[1] showing a large decomposition of cyanide and also a considerable precipitation of precious metals, due to contact with wood, canvas, cocoa matting,

and other fabrics used as filters, being all forms of cellulose. Some of the writers, working on a laboratory scale, had failed to take into account the ratio of the surface of the precipitating material they used to the volume of solution experimented upon, and did not then compare this ratio with that which would have resulted by working on a large scale. Consequently some operators have been misled, believing that discrepancies in cleaning up were attributable to precipitation by the wood of tanks or filter bottoms, and therefore were induced to hope that at some future date the burning of the material would reimburse them for their supposed losses. As these writers differed considerably either in their opinions or in experimental results, we give some of our results obtained by examination of materials that had been exposed to gold and silver-bearing solutions for considerable periods.

(1) Materials from a sand leaching tank. This was nearly 40 ft. diam., the bottom having an area of 1200 sq. ft. It had been in use over a year when the first tests were made. The quantities given represent the contents of the entire material in the tank, through which many thousands of tons of solution had circulated, carrying up to $6 per ton in gold, and up to $2 silver.

(*a*) Bottom filter cloth of canvas; 8-oz. duck, 1200 sq. ft., in use for 8 months. Entire cloth: gold, 5c.; silver, 2.

(*b*) Bottom filter of cocoa matting; 1200 sq. ft., in use 12 months. Entire filter: gold, 46c.; silver, 3.

(*c*) Wooden slats. These supported the filter, and were of unpainted Oregon pine, 3800 running feet with a cross-section of 2.5 by 1.5 in., about a quarter of the material being erozed out; altogether about 75 cu. ft.; in use 12 months; entire material, gold, $16.60; silver, $5.90; wood per cubic foot, gold, 22c.; silver, 8.

(*d*) Fine slime. This had accumulated under and between the filters during 8 months, and consisted of fine ore together with precipitated carbonate of lime; altogether 200 dry pounds; entire material: gold, 20c.; silver, 4. In the last case, and probably in all, most of the gold and silver was contained in solution absorbed and not necessarily precipitated.

(2) Tank staves. (*a*) The staves of a similar large leaching tank, after use between three and four years, with sand averaging $3 gold and $1 silver per ton; made of California redwood, originally painted inside with two coats of P. & B. paint, and outside with red oxide of iron in linseed oil; a slight coating of carbonate of lime had formed on the inside; a large sample from these staves, burned and assayed, yielded only traces of gold and silver.

(*b*) Similar staves from a leaching tank in use at another plant for four years contained 40% moisture; the dried wood contained gold, 47c. per ton; silver, 3.

(3) Precipitating box. A precipitating box of 1½-in. lumber was painted inside and out with P. & B. paint, and used three years to precipitate low-grade cyanide solutions with zinc shavings, the slime averaging $4 to $5 per pound. Samples were taken by boring completely through the wood at various points in sides and bottom, and were burned and assayed. A little zinc slime was visible on the surface. The average value of the material, including a trace of adhering precipitate, was, sides, 0.75c. per square foot; bottom, 2.

(4) Mine timber. A piece of blackened but sound timber (yellow pine) which had been some time underground, and contained ferrous and ferric sulphates derived from mine-water, was tested. At the time of the test it contained 56% of water. Kept in contact with about three times its weight of cyanide solution, which assayed $1.20 per ton in gold, no precipitation took place in 20 hr. It seems evident, therefore, that wood, when well painted with any suitable protective medium, absorbs little more than traces of precious metal from cyanide solutions of ordinary value.[2] As dry pine and redwood absorb about their own weight of water, one would expect such wood, if dried after a thorough soaking in solution, to assay the same per ton as the solution taken up, evaporation and precipitation excluded. Alternate soaking and drying, or evaporation on the outside of wooden tanks in a dry climate, might be expected to result in a distinctly higher assay value in the wood. Adhesion of rich telluride slime or floured amalgam may also cause an increased value. It is difficult, however, to reconcile the results obtained by the following experimenters, and only those of F. L. Bosqui are at all in line with our own experiences. The other writers worked entirely on a laboratory scale. S. H. Williams found that an 8-in. wooden launder, 75 ft. long, used 7 months at a cyanide plant in New Mexico, having passed 63,000 tons of solution, worth $3 per ton, contained 2.766 oz. gold and 32.646 oz. silver in 15.5 cu. ft., or 0.18 oz. gold and 2.1 silver, per cubic foot, or a total value of about $4.65 per cubic foot. An apparent typographical error in the original article makes the value $60.45 per cubic foot. A. N. Maekay states that red pine, from a tank used 18 months, in which had been treated only 1200 tons of ore containing 20 dwt. gold per ton, yielded 12.4 oz. gold per ton of wood. F. L. Bosqui experimented with pine and redwood, dressed and rough, both with intermittent exposure and drying, and with continuous immersion, for periods up to 12 months, using solution which averaged $5 gold per ton and some silver. The highest absorption was with rough pine, exposed altogether about 12 months; $5.18 gold and 14c. silver.

On the whole, it seems probable that the precipitative effect of charcoal may be from occluded gases, but definite proof is lacking. S. Brussow, in a recent article, attributed the precipitation of gold from haloid salts by charcoal to absorption. This seems most unlikely, as he admits that the chlorine of gold chloride remained almost entirely in the solution; and we have found that charcoal which has been in contact with solutions of either chloride or double cyanide of gold, is thoroughly impregnated with metallic gold, easily distinguishable with a good lens.

[2] When launders of unpainted wood are used in the Plattner chlorination process they absorb gold enough to make it worth while to burn them to recover it. The same is true of canvas used for concentration in mills where floured amalgam escapes the plates, or where the tailing contains fine gold or rich tellurides. Absorption of silver similarly takes place in hyposulphite leaching. This is preventable by soaking the wood in hot paraffine or painting with asphaltum.

ELEVENTH INTERNATIONAL CONGRESS OF GEOLOGISTS, STOCKHOLM, 1910

This congress is to be held in Stockholm, August 18-25. The deliberations will be principally concerned with the following questions:

1. Geology of the Pre-Cambrian Systems. The discussion is divided into the debate of the following special questions: (a) to what extent can it be proved that the characters of Archean rocks are due to a deep-seated metamorphosis? and (b) the principles of a classification of the pre-Cambrian formations. The following gentlemen will participate in this discussion: F. D. Adams, Ch. Barrois, F. Beeke, U. Grubenmann, J. F. Kemp, A. C. Lane, J. J. Sederholm and P. Termier.

2. Abrupt Appearance of the Cambrian Fauna: Ch. Lapworth, G. F. Matthew, A. Rothpletz, C. D. Walcott, and J. Walther have promised contributions.

3. Changes of the Climate Since the Maximum of the Last Glaciation: As an introduction to this discussion three Swedish scientists (G. Anderson, G. De Geer, and R. Sernander) published last spring observations in Sweden, in explanation of the postglacial climatic deviations in that country. These three essays were sent to a considerable number of foreign scientific men that have occupied themselves with the question of postglacial climate, and these gentlemen were requested to co-operate in an international discussion of this problem. Already several treatises have been sent in and scientists from the following countries have promised their co-operation: Austria, Belgium, Canada, the Cape Colony, Denmark, Egypt, England, Finland, France, Germany, Hungary, India, Italy, Norway, Russia, Sweden, Switzerland. Reports on the arctic and antartic regions have also been received. The treatises will be collected in a single work: 'The Changes of Climate Since the Maximum of the Last Glaciation.' This publication, which will probably be ready in the course of the month of April, will form the basis of the coming discussion. It will be sent free of cost to the contributors. It will also be procurable, at a price not yet fixed, from the publisher, 'Generalstabens Litografiska Anstalt', Stockholm 3.

4. The Iron Ore Resources of the World: In the beginning of 1908 the committee of the congress sent to the national geological institutions and to the mining geologists in the different States invitations to take part in an exhaustive investigation of the above question. This request has everywhere met with so much attention that, at present, reports from nearly all the iron-ore producing countries of the world have been received. These will be collected in one work: 'The Iron-Ore Resources of the World.' This publication, consisting of about 900 pages in quarto, with numerous plates and illustrations in the text and accompanied by an atlas of 40 map-sheets, will shortly be ready. It will be sent free of cost to the governments of the co-operating States and to the collaborators, and it will also be procurable from the above-mentioned publisher at a price of £3.

5. Geology of the Polar Regions: This subject will be treated in a series of special lectures, of which the following may be announced: H. Jarner, 'The Geological Results of the *Danmark* Expedition to Northeastern Greenland'; A. G. Nathorst, 'The Climatic Testimony of the Fossil Floras in the Polar Regions'; J. F. Pompeckj, 'The Jurassic Deposits of the Arctic Region'; N. V. Ussing, 'The Eruptive Area of Tlimausak—Western Greenland'. One of the geologists of the last British Antarctic Expedition will also give a report on its geological results. In connection with the discussion there will be an exhibition of the geological collections brought home by Swedish expeditions from the arctic and antarctic regions.

The debates of the congress will principally relate to the discussion of the above questions. Isolated lectures, of which the committee has been informed, will be placed in one of the following sections: (1) General and regional geology. Tectonic matters. (2) Petrography and mineralogy. (3) Stratigraphy and paleontology. (4) Quaternary formations. Recent glaciers. (5) Applied geology.

In connection with the congress the following excursions will be arranged:

A. Excursions before the Congress. 1. Spitzbergen, July 25 to August 17. Leader: G. De Geer. 2. Norrland (over-thrusts, eruptives, iron ore fields), July 27 to August 17. Leaders: A. G. Högbom, Hj. Lundbohm, and P. J. Holmquist. 3. Iron-ore fields of Gellivare and Kirunavaara, August 6-17. Leader: Hj. Lundbohm. 4. Quaternary geology of the Torneträsk, August 6-17. Leader: O. Sjögren. 5. The Alps of Sarek, July 27 to August 17. Leader: A. Hamberg. 6. Quaternary geology of Angermanland and Jämtland, August 9-17. Leader: A. G. Högbom. 7. Peat-moors of Närke, August 10-16. Leader: L. v. Post.

B. Excursions during the Congress. Several excursions of one day, principally in the environs of Stockholm.

C. Excursions immediately after the Congress. 1. The Archean rocks of middle Sweden, August 26 to September 4. Leaders: A. G. Högbom, P. J. Holmquist, A. Gavelin, and H. Hedström. 2. Silurian deposits of Gotland, Dalarne, and Västergötland, August 25 to September 6. Leaders: H. Munthe, H. Hedström, C. Wiman, and E. Warburg. 3. Quaternary geology of southern Sweden, August 26 to September 8. Leaders: G. De Geer, H. Munthe, and A. G. Nathorst. 4. Ore fields of middle Sweden, August 26 to September 6. Leaders: Hj. Sjögren, W. Petersson, and H. Johansson. 5. Morphology of middle Sweden, August 26 to September 4. Leaders: O. Nordenskjöld and S. De Geer. 6. Plant-containing Mesozoic deposits in Skaane, August 26-29. Leader: A. G. Nathorst. 7. Cretaceous system in Skaane, August 25-29. Leader: A. Hennig.

D. Excursion in Skaane, after the conclusion of group C. Silurian deposits, September 7-13. Leader: J. C. Moberg.

A second circular of the congress containing full particulars about the excursions and a statement of costs is promised. All correspondence relating to the congress to be addressed to the secretary-general, Professor J. G. Anderson, Stockholm 3.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Some Words and Their Meaning

The Editor:

Sir—In a brief article by me recently published in your paper, the proof-reader changed the words 'overlies' and 'overlain' to 'overlays' and 'overlaid'. As there seems to be a difference of opinion among some geological writers as to which usage is correct for these much employed terms, it occurred to me that the following little table might be instructive to those who consider the question a debatable one. A clear understanding of this minor point of grammatical usage is certainly desirable and would smooth the way for both editor and author:

Intransitive verb *to lie*	Transitive verb *to lay*		
Correct usage.	Correct usage.	Correct usage.	Incorrect usage.
The bed of sandstone *lies over* the bed of limestone. (Primitive form.)	The jeweler *lays* enamel *over* gold. (Primitive form.)	The cabinet-maker *lays* holly in mahogany. (Primitive form.)	The bed of sandstone *lays over* the bed of limestone. (What does it lay over the limestone?)
The sandstone *overlies* the limestone. (Derivative form.)	The jeweler *overlays* gold with enamel. (Derivative form.)	The cabinet-maker *inlays* mahogany with holly. (Derivative form.)	The sandstone *overlays* the limestone. (With what?)
The sandstone once *overlay* the limestone.	The jeweler *overlaid* gold with enamel.	The cabinet-maker *inlaid* mahogany with holly.	The sandstone once *overlaid* the limestone. (With what?)
The limestone is *overlain* by sandstone.	The gold is *overlaid* with enamel. (By the jeweler.)	The mahogany is *inlaid* with holly. (By the cabinet maker.)	The limestone is *overlaid* with sandstone. (By whom?)

A little attention to the derivations, uses, and analogies suggested by the table makes evident the fact that the writer, whose sentence reads, "This formation is overlaid by conglomerate", is confusing the verbs *to lie* and *to lay*, and may consistently be expected to exclaim, 'Oh, go lay down!'

Washington, February 27.

Leasing Public Oil Lands

The Editor:

Sir—Senate Bill No. 5488 is the administration measure on oil lands and has received the general approval of Mr. Gifford Pinchot, president of the Conservation Commission. It is desirable to enact a bill providing for permits to prospect and for leases on public lands for oil and gas in place of the present 'oil-placer' law. Yet I find a number of objections to this bill. If the bill should pass in its present form it will greatly retard the development of oil and gas in the Rocky Mountain States. Inasmuch as the oil produced in these is in such great demand as to bring $1.50 to $2 per barrel in comparison with the 35c. of Oklahoma, and the approximate 63c. of California, this clearly would be opposed to the public interest. The words "to which patents have not been earned" may do serious injustice to oil-placer mining claims that were located prior to the passing of this bill and on which the term in which assessment work must be done and discovery made, has not elapsed. It would seem desirable to add a provision that oil-placer mining claims upon which location had been made prior to the signing of the act may be patented when the provisions of that law have been fulfilled. Section 2 fails to make clear that the person taking out a permit to prospect shall have a preference right to lease the land that he has demonstrated under that permit to be oil-bearing. The bill is lacking in not stipulating further upon this point.

The provision that 320 acres may be leased is general, applying to all classes of oil lands, although there is the utmost variation in their nature. In the case of wildcat wells in Rocky Mountain States many miles from any producing well, some larger reward than this should be offered the prospector for the expensive drilling of a pioneer well. A classification of oil lands should be adopted so that the size of a lease may be greater in such cases.

It is also unfair to the driller of an oil well to cancel his lease at the end of ten years. The oil operator must be able to recoup himself amply on large successful wells to pay for the losses of failures and small wells. The leases should read "as long as oil and gas are found in paying quantities" which is the usual form of commercial leases. This also prevents the hasty and too close drilling of a lease in the effort to get as much oil as possible in the ten years. In the interests of conservation the operator should not be hurried, once a lease is shown to be productive. The tendency to over-production is too great as it is.

The Secretary of the Interior should not be given authority to cancel a lease for failure to operate inasmuch as provision for the payment of rental is provided for in the bill, and such a liability makes the value of a lease so uncertain and arbitrary as to seriously interfere with values. This proviso flies directly in the face of the spirit of conservation manifest in many other parts of the bill. Any operator who will pay the Government a rental year by year to protect a lease is performing a service for conservation and should not be disturbed. The bill is also faulty in lacking provisions against wasteful operations. The drilling of wells within a specified distance of the boundary line of a lease, say 200 ft., should be prohibited.

It is very gratifying to find, in spite of these defects, arising from failure to grasp the complexity

of the situation, that with the exception of the two clauses which have been pointed out, the spirit of conservation dominates the bill. There has been an apparent opposition between the presidential attitude and that of the Department of the Interior in the matter of conservation. The Department has forced, and is still forcing, wasteful drilling in Oklahoma on Indian leases by demanding annually advancing payments and requiring drilling within five years regardless of the demand for oil. Evidently in the elaboration of this bill the presidential attitude has prevailed.

ROSWELL H. JOHNSON.

Bartlesville, Oklahoma, April 2.

Estimation of Cyanide in Solution

The Editor:

Sir—In your issue of January 15, which has just reached me, I note a discussion by Algernon Del Mar on the above topic in which he quotes the different quantities of $AgNO_3$ recommended by different writers for making the $AgNO_3$ standard solution, and asks which is the correct quantity to use in practical cyanide work.

Consideration of an example or two based on the chemical equation representing the reaction of $AgNO_3$ with KCN may serve to show what effect the apparent discrepancy would have on practical work. Assume a mill solution containing a given amount of KCN per ton, and also assume that an $AgNO_3$ solution of 13.043 gm. per litre is the correct one. Titrate 20 c.c. of the mill solution and suppose that it requires 1 c.c. of $AgNO_3$ solution to reach the end point. Then evidently the mill solution contains 1 lb. KCN per ton. Now for comparison titrate an equal sample of the same mill solution with an $AgNO_3$ solution of 13.07 gm. $AgNO_3$ per litre. As this solution is stronger than the first it is evident that it will require a less number of cubic centimetres. The amount required may be calculated by solving the following simple proportions:

0.01307 gm. : 0.013043 : : 1 c.c. : X c.c.
or X = 0.99898.

That is, using the last solution we have an error of 0.00192 c.c. which is manifestly too small to be noted on the burette. In round numbers the error is 0.2%. If titrating a 20-lb. solution of KCN the second $AgNO_3$ solution then would give 19.96 c.c., or 0.04 c.c. less, which in this particular titration means absolutely nothing because of the indefiniteness of the end point caused by the influence of substances other than KCN that are always found in working solutions, besides being an amount that can not be read with accuracy on the ordinary burette. It is useless to carry refinements based upon difference of atomic weights of the same element as they have been determined in the last decade, into the mill laboratory for the daily determinations, whose value do not so much depend upon their accuracy to within 0.2% of the true amount, but upon their true relative relations. What is needed in the laboratory is accuracy and care, in weighing, titrating, and other manipulations, balancing their relative importance. The nearer work in the laboratory approaches the construction of the 'One Horse Shay', the more uniform and efficient will it become.

D. C. WOODWARD.

Petorea, Chile, March 5.

COAL-MINING AND COKE-MAKING AT DAWSON, NEW MEXICO

By E. W. PARKER

*The plant of the Stag Canyon Fuel Co., which represents one of the highest types of coal-mining development in the United States, is located at Dawson, Colfax county, New Mexico, in townships 28 and 29 N., R. 20 E., and T. 28 N., R. 21 E. The coal property embraces part of the Raton Mountain region, and includes operations in and about Trinidad, Colorado, and Raton, Koehler, Van Houten, and Dawson, New Mexico. There are two workable beds in the field, only one of which is being mined at the present time. The Dawson mines are on the lower of the two workable seams, known as the Raton or Blossburg bed. It lies nearly level and varies from 6 to 11 ft. thick, with an average of about 7 ft. The mining company is a subsidiary organization of the Phelps, Dodge & Co., Inc., and the idealistic character of the plant is due to the influence of James Douglas, the president of the company, and to the administrative genius of E. L. Carpenter, its general manager. The mining methods of the company, and the arrangements for handling the coal and preparing it for the coke ovens, are strictly modern throughout. Instead of the ordinary bee-hive coke ovens, modified underflue ovens are employed by which the gases from the coking operations are used for heating the ovens and also for generating the power used in the operation of the mines, the heating of the office, and other company buildings, and for furnishing electric light to the town. Not a pound of coal is used in the power plant, which is a model of neatness and efficiency.

Special provisions are made for the safety of the miners and other employees, and no shot-firing is done while any of the miners are within the mines. Careful supervision is exercised over the methods of undercutting and shearing coal and of placing shots, in order to avoid any possibility of windy or blown-out shots. A checking system is employed by which it is known that all employees are out of the mines before the shot-firers enter. The shot-firers make the electric connections, and after they have left the mines, the entrances are closed by iron gates and a red light is exposed in front of each gate in order to warn persons away and thus avoid accidents from flying débris, in case an explosion should occur. The Stag Canyon Co. further trains its men in first aid to the injured work; conducts a rescue station in which men are instructed in the handling of rescue apparatus, and a hospital service, provided for the employees at a minimum expense.

* Read before the Washington Geological Society and abstracted from *Science*.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Heat and light are both forms of undulatory waves and are transmitted through space at the same rate, 186,000 miles per second.

At the present increasing rate of production the available and easily accessible supplies of iron ore in the United States will approach exhaustion before the middle of the next century.

Oil placer-claims may be held by doing annual labor on one for the benefit of not to exceed five claims. The number of claims which may be held as a group by annual labor within or outside of them is immaterial in the case of other placer locations, so long as the character of the work is such as court decisions have shown to be acceptable.

Conflict between two claimants arose as follows: A located a quartz lode claim on June 1, 1909, and B located another, crossing A's at right angles, on July 1, 1909. A failed to perform the annual labor necessary to hold his claim in 1910, and B then claimed the area under conflict at the crossing of the claims. The junior location (B's) acquired no rights in the area in conflict at the time of location, and consequently the area in dispute could be obtained only by re-location.

Mercury is no longer extracted from its ores by pot-roasting with lime or iron. It can only be done at a profit when the ore is extremely rich. It is also open to the serious objection of imperilling the health of the workmen, who are necessarily exposed to the mercurial vapors. This difficulty does not exist with shaft-furnace distillation, the vapors being at all times confined in flues and chambers which under-exhaust so that passage to the outer air is prevented.

Notices of location of lode, placer, tunnel, or mill-site claims in California must be recorded within 30 days from the date of location in the office of the County Recorder for the county in which the location is situated. There still remain a number of mining districts organized as provided in the Federal mining law, and where such exist it is desirable to avoid possible cloud of title by having notice of location recorded with the District Recorder as well as with the County Recorder.

Weathering action of the air is partly due to its ordinary oxidizing power, but even more to the carbonic acid which it contains. Although amounting by weight to only about 0.034% as against 21 of oxygen, the carbonic acid in the atmosphere shows surprisingly powerful chemical properties. Under conditions controlled by the chemist, carbonic acid may be regarded as the weakest of inorganic acids, but when dissolved in surface or other waters, and particularly when absorbed merely by moisture where it has the maximum surface action, it possesses the power of gradually decomposing most of the rock-forming silicates. Under such conditions, silica itself is only a weak acid and is readily expelled from many of its compounds and carried away in solution as free silicic acid in colloidal or other form or as an alkaline silicate, to re-appear in one or other of the many forms of which vein quartz, chalcedony, agate, jasper, opal, and the like, are familiar examples.

Antimony ore is generally liquated in reverberatory furnaces. The ore should be broken to about the size of walnuts, and brought to a low red heat. At that temperature the antimony sulphide melts and flows out from the ore, and can be drawn from the sloping hearth of the furnace. At a higher temperature the antimony sulphide is volatilized. If much fine ore is present this process is not successful. Cylindrical revolving furnaces are also used for the liquation of antimony ore.

Pegmatite may be regarded as a giant variety of granite, the essential minerals occurring in very large crystals. Pegmatites have probably been produced by igneous intrusions around granite masses, and it would seem that heated vapors and solutions, forming part of the intrusions, are in a large measure responsible for their formation. This view is supported by the frequent occurrence of pegmateites of a variety of rare minerals, few, if any, of which occur in the surrounding rock. The pegmatites supply the feldspar, mica, and some of the quartz of commerce, these minerals being present in such form as to admit of easy separation.

Relative cost of electric and steam power at isolated plants varies according to conditions. For a specific case they may be calculated as follows: With a 160-hp., non-condensing, slide-valve engine; coal screenings costing $2.50 per ton of 2000 lb.; labor, $3.50 per shift; operating time, 11 hr. per day; cost of electric power, 2c. per kw. hour, and assuming, (1) continuous full load, (2) boiler evaporating 6 lb. of water from and at 212°F. per pound of coal, (3) feed-water heater delivering water at 200°F.; (4) no allowance for oil, waste, supplies, water, or interest on plant; (5) steam consumption of engine, 35 lb. per hp. hour; (6) steam pressure, 100 lb. per sq. in. Then steam required per hour equals 160 (hp.) by 35 (lb.) = 5600 lb. per hr. With feed-water at 200° and 100-lb. pressure, 1 lb. coal will evaporate 6 (lb.) ÷ 1.0523 (factor of evaporation) = 5.70 lb. The pounds of coal required will, therefore, be 5600 ÷ 5.7 = 965. This amount per hour, 965, by 11 (hours per shift) = 10,615 lb. or 5.3 tons of coal per day. This coal 5.3 (tons) at $2.50 per ton, will cost $13.25 per day. If to this $3.50 be added to cover wages for one man, the total cost for fuel and labor will be $13.25 + $3.50 = $16.75 for steam power. The cost of electric power may be figured as follows: 160 hp. = 120 kw. which for 11 hours = 120 × 11 = 1320 kw. hr. per day, 1320 × 2 (cents per kw. hr.) = $26.40 per day for electric power. Under the assumed conditions the steam power would evidently be cheaper. By substituting other figures to correspond to other assumptions, the cost under a variety of cases can be readily found.

Special Correspondence

WASHINGTON, D. C.

Administration Bill for Leasing Phosphate, Oil, Asphaltum, and Natural Gas-Bearing Lands.

The administration bill (S.5488) for the disposal by lease of the phosphate, oil, asphaltum, and natural gas lands, changes existing law in so many particulars that it may be quoted entire. The bill was introduced in the Senate by Mr. Nelson, of Minnesota, and is now before the committee on public land. It reads as follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That all lands within the United States or the Territory of Alaska to which patents have not been earned and which contain deposits of phosphate, oil, asphaltum, or natural gas, and the phosphate, oil, asphaltum, or natural gas therein, are hereby reserved from all forms of entry, appropriation, and disposal, except under the provisions of this Act.

SEC. 2. That any person above the age of twenty-one years who is a citizen of the United States, and any association of persons, corporate or otherwise, on the payment in each case of an application fee of $10, may apply under the following provisions of this Act for the exclusive right to prospect for or lease any phosphate, oil, asphaltum, or natural gas deposits owned by the United States: *Provided,* That to prevent monopoly, the Secretary of the Interior is hereby authorized to limit the number of permits or leases issued to any individual, association, or corporation under the provisions of this Act or deny any application for the right to prospect or for a license or lease if he shall find that such application is not made in good faith by the applicant or is an attempt to monopolize or control the said deposits or the output or price thereof.

SEC. 3. That the Secretary of the Interior is hereby authorized, in his discretion and under such rules and regulations as he may prescribe, on the payment of a rental of not less than 10c. per acre, but not less than $10 in any case, to grant to any qualified applicant a prospecting permit, which shall give the exclusive right for a period of not exceeding two years, to prospect for phosphate, oil, asphaltum, or natural gas on a specified area, in compact form, not exceeding 1280 acres in case of phosphate, or 640 acres in case of oil, asphaltum, or natural gas, of any lands wherein the phosphate, oil, asphaltum, or gas is reserved to the United States by this Act, and to lease not more than 640 acres in case of phosphate, and not more than 320 acres in case of oil, asphaltum, or natural gas, under the provisions of this Act.

SEC. 4. That the Secretary of the Interior is hereby authorized, in his discretion and under such rules and regulations as he may prescribe, to execute in the name of and on behalf of the United States and to issue to any qualified applicant a lease for not more than 640 acres in case of phosphate, and not more than 320 acres in case of oil, asphaltum, or gas, in compact form, and of such shape as he may fix, in legal subdivisions, subdivided into ten-acre tracts where advisable, conforming to the public-land surveys, and, if on unsurveyed lands, to the rectangular system thereof, in tracts of ten acres or multiples thereof, conveying the right to develop, extract, and dispose of phosphate, oil, asphaltum, or gas from any lands subject to the provisions of this Act, under such conditions conserving the public interest, including among others covenants relative to mining methods and waste, to a period of preliminary development and quality of production, as he may prescribe: *Provided,* That the first period of any lease shall not exceed 30 years in case of phosphate, and 10 years in case of oil, asphaltum, or gas, but any lease may be extended in periods of 10 years in case of phosphate, and 5 years in case of oil, asphaltum, or gas, on such terms, conforming to prevailing commercial practice, and under such conditions as the Secretary of the Interior may prescribe: *Provided further,* That in the lease to any tract a royalty not exceeding 10% in case of phosphate, and 15% in case of oil, asphaltum, or gas, of the gross value of the output at point of production, shall be stipulated, and that there shall be paid in advance a rental of 50c. per acre in case of oil, asphaltum, or gas for the first calendar year or fraction thereof, and $1 per acre thereafter during the continuance of the lease, and in case of phosphate 10c. per acre for the first calendar year or fraction thereof, 25c. for the second year, 50c. for the third year, 75c. for the fourth year, and $1 per acre thereafter during the continuance of the lease; but the rental for any one year shall be a credit on the royalty for that year: *Provided, nevertheless,* That the Secretary of the Interior may reserve authority in any lease to cancel such lease for failure to operate or mine.

SEC. 5. That * * * all payments * * * shall be made to such officer as the Secretary of the Interior may designate.

SEC. 6. Provides for bonds for payment of all moneys or damages which may accrue, and "for the faithful performance of all Acts, duties, and obligations imposed by such permit or lease, and for indemnification of the United States against mechanics' or laborers' liens, taxes, or assessments."

SEC. 7. That no lease shall be assigned, mortgaged, or sublet, except with the permission and approval of the Secretary of the Interior and under such conditions as he may prescribe * * *.

SEC. 8. That a lease may, in the discretion of the Secretary of the Interior, be terminated upon the written request of the lessee to the Secretary of the Interior, and after due opportunity has been afforded to said Secretary to examine into the condition of the property.

SEC. 9. That in case a lease is terminated, either by the expiration of the period fixed therein, by relinquishment, or by forfeiture, the right is reserved to the retiring lessee to dispose in the open market of such of the buildings, machinery, and other improvements as in the opinion of the Secretary of the Interior can be removed without injury to the leasehold; but the retiring lessee shall forfeit all right to so much of these improvements as the Secretary of the Interior may deem necessary to withhold: *Provided,* That if the Secretary of the Interior shall re-let the remainder of the phosphate, oil, or gas covered by the former lease, he shall provide that reasonable and just compensation shall be paid by the new lessee to the former lessee or his representatives for remaining structures, fixtures, or improvements. If the retiring and incoming lessee can not agree as to the price, each shall appoint one member of a board of appraisers, and the Secretary of the Interior shall appoint a third, and the decisions of this board shall be accepted as final.

SEC. 10. That any person or persons to whom the Secretary of the Interior shall grant a permit to prospect for or a lease to develop and extract phosphate, oil, asphaltum, or gas, under the provisions of this Act, shall have the right to use so much of the surface as shall be determined from time to time by the Secretary of the Interior to be necessary for the proper prospecting, development, extraction, handling, treatment, and transportation of such phosphate, oil, asphaltum, or gas; but such permittees and lessees shall compensate all settlers, entrymen, and owners of any lands embraced in their permits or leases for all loss or damage sustained by such settlers, entrymen, and owners by reason of such prospecting, development, extraction, handling, treatment, and transportation; and, whenever such settlers, entrymen, or owners, and such permittees or lessees shall fail to agree on the amount of any damage or loss claimed under this section, the amount of such damage or loss, if any, shall be determined by appropriate proceedings instituted by either of said parties in the United States courts having jurisdiction over the subject-matter.

SEC. 11. That the Secretary of the Interior may withdraw from entry, occupation, or settlement any unappropriated public lands, the surface of which he may deem necessary for use in connection with the production, handling, or transportation of phosphate, oil, asphaltum, or gas under this Act. Such lands shall be withdrawn only in areas necessary for the purpose, which may include tracts less

than the usual public land subdivisions, and the Secretary of the Interior may cause to be made, in any manner he may decide, surveys necessary for such segregation. Upon the release from withdrawal of any tract which lies within the limits of any area for which entry has been made, the entryman shall have the right to amend his entry to include such tract, making additional payment when it would have been required if the tract had been included in the original entry; and, if patent has issued, the patentee, or his successor in interest, shall be entitled to a patent for such tract upon like conditions. In case of failure to apply for such amendment of entry or patent within six months after such release, the tract shall be subject to appropriation under the public land laws.

SEC. 12. That a failure of any lessee to comply with the terms and conditions of the lease shall work a forfeiture and cancellation of the same; and the Secretary of the Interior shall have the power to declare and enforce, by appropriate judicial proceedings, such forfeiture and cancellation.

SEC. 13. That leases executed and issued under the provisions of this Act shall also fix maximum prices or rates beyond which the lessee shall not charge the public for phosphate, oil, asphaltum, or natural gas extracted under the lease, and appropriate provisions for re-entry or forfeiture in case of violation of such provisions; and such prices or rates may be graduated during the term of the lease.

SEC. 14. That the laws of the State or Territory in which the land is situated for control of inspections and the operations of mining shall apply to operations under the leases herein authorized, in so far as they are applicable, except where such laws are in conflict with the provisions of this Act, and the Secretary of the Interior may also from time to time promulgate reasonable rules and regulations as to the methods of mining, the character of machinery or safety appliances to be employed, and requiring the most approved methods and devices for the safety and protection of the miners and other employees in the operations conducted under such lease, which regulations shall be binding upon the lessees in like manner as if set forth and contained in the lease.

SEC. 15. Gives the Secretary of the Interior or his agents the right to require written statements of any and all acts performed or of any and all moneys received, and to examine all books and records relating to corporate organization or to transactions under such leases.

SEC. 16. That to mine, produce, or remove phosphate, oil, or gas belonging to the United States, without authority derived from the Secretary of the Interior, shall constitute a trespass, punishable upon conviction by a fine not exceeding $1000 or imprisonment for not exceeding one year, or both.

SEC. 17. That the Secretary of the Interior is hereby authorized to perform, or cause to be performed, any and all acts, and to make such rules and regulations as he may deem necessary and proper for the purpose of carrying the provisions of this Act into full force and effect, and all leases, foreclosures, purchases, or assignments shall be subject to such rules and regulations.

SEC. 18. That all unappropriated and unreserved public lands within the United States and the Territory of Alaska may be settled upon, entered, located, or selected under any of the non-mineral public land laws applicable thereto, notwithstanding the existence of deposits or phosphate, oil, asphaltum, or natural gas therein, and may be patented upon satisfactory proof of due compliance with the laws under which such lands are claimed; but all patents for such lands shall contain a reservation to the United States and its lessees of all phosphate, oil, asphaltum, or natural gas therein, and of the right to the free use and occupation of such of the surface of the lands so patented as may be necessary to the mining, removal, and sale of such phosphate, oil, asphaltum, or natural gas: *Provided*, That the Secretary of the Interior may withhold from settlement, entry, location, or selection the surface of any lands classified as containing phosphate, oil, asphaltum, or natural gas until such time as, in his opinion, said surface may be disposed of without detriment to the prospecting for, or removal in the manner provided in this Act, of such deposits of phosphate, oil, asphaltum, or natural gas.

SEC. 19. That no phosphate produced under any lease authorized by this Act shall be exported or taken from the United States or the Territory of Alaska, except that phosphate so produced in Alaska may be brought into and used within the United States.

SEC. 20. The jurisdiction to determine the issues and matters which are by this Act committed to the courts is hereby conferred upon the United States circuit and district courts for the districts in which the lands, leaseholds, or property are situated or located.

SEC. 21. Repeals conflicting laws "except as to valid claims existent at date of the passage of this Act."

DENVER.

Boulder District Active. — San Juan Projects. — Supreme Court Decision.—Land Fraud Case. — The Oil Industry. — Cripple Creek Items.

Mining operators in the Boulder district have been especially favored during March. It is now one of the most active camps in the State. The warm open weather has permitted construction to be pushed rapidly, and many of the mines are now in position to take advantage of the high price of tungsten which is above that of any time since 1907. Many of the gold-producing mines report new ore-shoots as the result of the development during the winter. The operators are just now a little worried lest the impending coal strike in the northern fields put them short of coal before power is available from the lines of the Northern Colorado Power Co. The Logan group of claims at Crismen, owned by the Clinton Mining Co., has been sold to A. S. Cox and associates. Mr. Cox was formerly superintendent of the property.

The San Juan region is still in the grasp of winter, and development is about all that can be done. The recently incorporated Colorado Smelting Co. is to erect a small plant two miles south of Ouray to treat the ores from the Black Diamond and Pony Express mines. Opinion seems to be changing again in favor of small smelting plants situated at or near the mines instead of the large centrally situated plants. It is noticeable that the large well equipped smelters at Pueblo, Salida, Leadville, and Denver are all running below capacity. The famous old Argo plant has ceased to operate and is being demolished. With the failures of the first craze for small smelting plants to guide them it is to be hoped that this second crop of small plants may be successful.

The Supreme Court has handed down an important decision regarding the cutting of timber on public lands. It has long been contended, and the contention upheld by the lower courts, that the law governing the cutting of timber for mining purposes gave the right to cut timber on the public lands in any part of the State. The Supreme Court decided that mine owners can cut timber for mining purposes on the public domain only in regions that are mineral in character, and that for use in that immediate district only. As a result of this decision, a shipment of timber for mining purposes has been seized at Canon City, and the Government has begun proceedings to recover the stumpage price on about 2,000,000 ft. of timber which has been cut from public land and used in different parts of the State.

Another land fraud case was begun at Cheyenne, Wyoming, March 31. The Government seeks to recover title to coal lands in the Elk Mountain district, and to iron lands in the Seminole. The lands are valued at $5,000,000. The suit has been brought against John D. Milliken and Charles S. Johnson, respectively, of the Northwestern Land & Iron Co., and the Denver, Laramie & Northwestern Railroad Co. It is alleged that the lands were secured by dummy entry practices.

In the Boulder oilfield an attempt is being made to confine the gas escaping from several wells in the field and pipe it to Boulder and surrounding towns. The chief dif-

ficulty anticipated is the separation of the gas and oil at the wells. The Holland syndicate, operating in the Dallas field near Lander, Wyoming, has let a contract for 25 new wells, 10 of them to be finished by June 1. The oil from this field finds a ready sale as locomotive fuel. Prospecting for oil has been carried on north and east of Colorado Springs for about two years with practically no results. Encouraging reports have lately come from near Falcon, and there is hope that a new field may be discovered.

The March production from Cripple Creek shows a gross value of $1,358,405. This is an improvement over February both in average grade of the ore and in tonnage. The local mills, however, treated somewhat less, due to the closing down of the cyanide mill owned by the Isabella Mines Co., and also to the suspension of treatment at the milling plant constructed on the property of the Trilby company. The directors of this company refused to accept the mill for alleged breach of contract and failure to make the guaranteed recovery. The Deep Drainage tunnel was advanced 344 ft. during March, and now measures 12,943 ft. from the portal. The breast of the tunnel is still in the hardest kind of Pike's Peak granite. The Doctor-Jack Pot and El Paso Consolidated companies paid March dividends amounting respectively to $15,000 and $24,500. The El Paso Consolidated is still controlled by Allan L. Burris who won over S. S. Bernard at the recent annual election.

LONDON.

San Francisco del Oro.—British South Africa.—Nundydroog.

The directors of the San Francisco del Oro have at last decided on the new system of treatment to be adopted. The company was originally formed in London in 1903 for the purpose of acquiring mines situated 14 miles southwest of Parral, Mexico. The surface ores were profitable to local owners who treated them for the silver content. Subsequently sulphides came in, and the ore became a complex mixture of blende, galena, and pyrite. It was attempted to smelt it in the Mexican furnaces and afterward some was sorted and shipped, but the owners decided eventually to sell, and to leave the burden of solving the metallurgical problem to other people. The English company which then took hold of the property found its way beset with difficulties and several methods were tried, such as chloridizing-roasting. There was always sufficient rich ore that could be shipped and enough has been sold to pay expenses. This policy was, however, considered a bad one, for not only did it mean leaving much ore behind but the cost per ton of extracting the rich ore was made high owing to so much unsalable ore having to be mined as well. It was in those days impossible to concentrate by jigs owing to the scarcity of water, and a trial of a dry table was made. This was a failure on account of the large amount of middling produced. Then a stroke of good fortune came to the mine in the form of an inflow of water at the lowest level, and by its means the mine was provided with a regular supply of 220 gal. per min. It was accordingly decided to adopt water concentration of the usual type and with large ore reserves it was felt justifiable last year to reconstruct on the basis of an assessment of 3s. on 330,000 shares. It was known fairly well that, by jigging, a good quality of lead concentrate could be obtained, but the question was to evolve a method of dealing with the zinc content. About 60% of the ore is sulphide, and 40% gangue, which latter consists of quartz, slate, calcite, and fluorspar. Of the silver content 50% is in the blende, 35 in the galena, and 15 in the gangue. The sulphides are intimately mixed and their separation involves the production of much slime. As regards the presence of calcite, experiment soon showed that acid-oil flotation processes would not help, while the fluorspar greatly diminishes the value of the zinc concentrate. This concentrate is not liberally treated by buyers in the matter of silver content, not more than 50% being paid for. Seeing that so much of the silver of the ore is in the zinc product, it is obviously to the advantage of the company to treat this product itself eventually.

The experimental operations have been conducted by Percy Tarbutt & Co., consulting engineers, W. S. Harrison, manager, and James Wilding, consulting metallurgist, on ore brought over to the Emu works near Swansea. It is reported that the smelting of the zinc product can be satisfactorily effected. A good extraction of the zinc and silver is obtained and the fluorspar content has been reduced to the required maximum. There are, however, many details still to be settled in connection with the zinc metallurgy, and the company has wisely accepted in the meantime an offer to purchase the zinc product made by a firm of zinc smelters. The terms of purchase will be sufficient to yield a small profit, and, for a time, until the company erects a smelter of its own, the deal is satisfactory.

The company will immediately proceed to erect a concentrating plant of sufficient capacity to treat 300 tons per day. This, and the necessary outlay on power and extension of the railway, will cost £46,000. With zinc at £20, lead at £13, and silver at 2s., the production of lead and zinc concentrates is expected by the engineers to yield an income of 37s. 6d. per ton of ore, and the total cost of mining and concentration is estimated at 16s. 6d., but close figures are not given in the report.

The British South Africa Co.'s report for the year ended March 30, 1909, has just made its appearance, and the meeting of stockholders was held this week. As regards mining history there is not much new in the report, for it is published a long time after the conclusion of the period covered. The important part of the report is that the accounts show a balance in favor of revenue. It now seems certain that from an administrative point of view Southern Rhodesia has arrived at a self-supporting stage, and that no more capital will be required. The revenue for the year was £551,789 and the expenditure £524,470. For the current year ending March 31, 1910, the expenditure was estimated to be £565,560, and it was proposed to spend all this and the balance from last year. It is stated that the results are proving to be better than the estimate; that the income will reach £600,000, and that there will be a saving in the expenditure. Northeastern Rhodesia and northwestern Rhodesia have not yet come forward and their revenues are small. The revenue and expenditure of the former during the year were £22,446 and £49,207, respectively; and of the latter £64,195 and £86,644. During the current year the figures for the former will be much the same as a year ago, but for the latter there will be slight increases in both income and expenditure.

The Nundydroog, in India, paid its largest dividend in 1909. Started in 1882, it was not until 1887 that production became active, and dividends were first paid in 1888. Since than the profits have gradually increased, though there were trifling waves of depression in 1893 and 1898. During 1909, the amount of ore crushed was 90,100 tons yielding 78,661 oz. bullion, and 84,240 tons of tailing gave 795 oz., the total value of the gold won being £346,470. The profit was £163,238, £113,200 has been distributed as dividend, being at the rate of 40%; £23,000 written off, and £20,000 placed to reserve fund. The formation of a reserve fund is in continuation of the new policy of paying for all expenditure out of profits instead of issuing new capital, and it will put the company in a strong position. The mine continues to develop satisfactorily, and the reserve on December 31 was 126,244 tons, an increase during the year. In January, 1909, operations were greatly impeded by a fire in one of the shafts. Considering this drawback, the excellence of the year's results is even more notable. It is interesting to mention that since the commencement of operations the mine has yielded gold to the value of £3,645,989, and distributed £1,540,535 as dividends. The company has acquired additional land between its mine and the property known as the Oriental block, which latter was purchased in 1904. By obtaining this extra piece of ground it will be possible to gain access underground to the Oriental block, and so the development will be facilitated. The company a year or two ago became interested in the Anantapur goldfield and last year took an option on the South Jibutil block. The developments this year have been promising and there is every prospect that the option will be exercised.

GOLDFIELD, NEVADA.

Consolidated Production.—Florence Development.—Combination Fraction.—Minor Leases.—Consolidated Mill Burns.

Production from the Clermont is now at the rate of 300 tons daily with about 200 tons each from the Mohawk, Combination, and Red Top shafts. An even production is maintained from the 260 and 330-ft. levels of the Red Top and the output from the Combination, including ore of good grade, has been increased. The deeper horizons of the Red Top vein will be developed by means of drifts from the Clermont workings. The stopes of the Mohawk continue to produce rich ore but a comparatively small amount of the high-grade is being broken. It is said that the orebody exposed on the 750-ft. level of the Clermont will average $500 per ton for a width of 6 to 10 ft., and a length of 200 ft. The entire mass, 25 ft. wide, is of excellent mill-grade, and the quality is well maintained on the 600-ft. level which is also yielding a large tonnage for the mill. High-grade ore has been developed in the Mohawk vein to a point near the boundary line of the Combination Fraction but no ore of commercial value has been opened by the long cross-cut driven at a depth of 600 ft. to the west from the Fraction and across the Combination claim. In the Lucky Boy claim the northwest lateral from the Clermont 600-ft. station has exposed some good milling ore.

The annual report of the Florence Goldfield Mining Co. has been issued. A marked improvement in the results of ore treatment is shown. Early in the year, when the first section of 20 stamps was placed in commission, the recovery was but 68.13%, but in December this had increased to 95.05%. The territory in which development has been centered is 650 ft. in length, but ore has been exposed almost continuously for nearly 1000 ft. in the main Florence vein where the vein matter is in some places 100 ft. wide. Low-grade ore has been cut in driving to the north toward the old Reilly lease workings over 1000 ft. north of the main shaft, and this drift, on the 350-ft. level, will shortly be connected by means of a raise with workings in which good ore is exposed from the 260-ft. horizon to the surface. Large bodies of mill ore have been exposed in old lease workings 400 ft. south of the shaft, and stopes are opened at intervals for a distance of 600 ft. One large vein, yielding assays up to $160 per ton, has been passed through in driving a connecting lateral between shaft 17 and the main shaft at a depth of 530 ft. This shaft is being enlarged from the 530-ft. level to the surface. The southern extremity of these workings is now in ground where a large amount of excellent ore is exposed to a depth of 570 ft. No development has been done at any point, except in this winze, below the 500-ft. level. One orebody of excellent character and marked uniformity in value has been opened for a length of 100 ft., and upward for 50 ft. above the 200-ft. level and is 12 ft. wide. Only ore exposed from two shafts has been sent to the mill and that developed from 13 others has not been touched. A considerable tonnage of good mill ore has been taken from the dumps of former leases, all of which operated under agreements making ore, valued at $30 per ton or less, the property of the Florence company. The Florence mill was first designed as a 20-stamp mill, with two tube-mills for regrinding and the necessary amalgamating, concentrating, and cyaniding equipment. Twenty auxiliary stamps were installed as a measure of protection against accident. Later experiments indicated that the equipment and capacity could be enlarged with small cost and resulted in the installation of four amalgamating plates, four Card concentrators, and one tube-mill. These changes resulted in increasing the capacity of the mill from 50 to 60% and in greatly increasing its efficiency. The report states that every variety of ore known to exist in Florence ground has been put through the mill. Experiments have been made having in view the construction of a plant for the treatment of concentrate on the ground by a process similar to that employed by the Consolidated company, but thus far the results have not warranted building such a plant.

Goldfield Consolidated Mill.

Development on the Combination Fraction, according to the manager, is meeting with highly satisfactory results at three levels. The orebody exposed on the 285-ft. level is being opened from the west lateral at 300-ft. depth, and has a good appearance. The best showing is on the 500-ft. level where the orebody is 15 ft. wide and of good grade. An improvement is noted in the assays taken from the quartz vein cut at the 750-ft. station and apparently a part of the Mohawk vein. A drift is being driven from this station to connect with the Clermont workings of the Consolidated for ventilation and to afford another outlet for production. On the Black Butte the company work is now confined to driving from the old shaft, which has been unwatered, to cut the vein exposed in a winze from the northern adit. This will reach the vein some 200 ft. below the adit-level. A shipment of good ore has been made from a lease on the western end of the Goldfield Daisy on ground formerly embraced in the Toplitz lease. Ore of milling grade has been secured in the cross-cut of the Precious Metals lease on the Atlanta at a depth of 730 ft. Shipping ore is being saved in the MacKay-Ford lease on the St. Ives claim of the Merger Mines Co. The Grizzly Bear shaft, now down 1150 ft., has cut stringers of ore and a cross-cut will be driven from the new station at the 1020-ft. level to penetrate the Mohawk vein. The Annex shaft on the Polverde claim of the Jumbo Extension Co. is produc-

ing ore of shipping grade from the raise above the drift on the 800-ft. level and the orebody is apparently of large dimensions.

An explosion of oil in the refinery of the Goldfield Consolidated mill started a fire that distroyed the refinery, the belt conveyor from the railway ore-bins through the sampler to the stamp-feed bins, the storehouses and contents, the sampling department and equipment, the change house, and the southeast corner of the mill proper. Of the 100 stamps 20 are completely tied up, but the other 80 could be started at once if there were any way of getting the ore into the mill. Duplicate parts have been ordered by telegraph and work commenced removing the wrecked portion of the mill. In the meantime the ore from the Consolidated properties will be treated at the local mills and the products usually handled by the refinery shipped to Selby or the mint. The damage has proved to be much less than at first anticipated. The loss is less than $200,000 and the entire plant will be again in operation within sixty days. Within thirty days it is expected that the destroyed belt conveyor from the crusher house will be replaced and operations with 80 of the 100 stamps will be resumed. Little if any gold was lost in the refinery. A considerable amount of bullion was contained in the retorts which were not injured and there was some precipitate in this department. During the period of reconstruction production will be curtailed, but development will be extended in all directions. Both Mr. Wingfield and Mr. Howe declare that the loss is not serious and that one week's mill run can readily be made to pay the amount of the damage. After the quarterly dividend of 50 cents per share is paid on April 30, the company will still have over $1,000,000 remaining in its treasury.

NEW YORK

Market Conditions. — Copper Surplus Increases. — Calumet & Hecla Changes.—Bisbee Results. — United Copper.

The collapse of the Granby; the formation of the Anaconda merger, without any particular opportunity for market action; the depression of Nevada Consolidated, evidently a move on the part of the Guggenheims to accumulate stock and complete their control of the company; these, in conjunction with generally unfavorable market conditions, have caused a slackening of interest in mining affairs, and an apathy which seems almost complete. The daily cables from London telling of furious business in rubber shares and oil shares has lent encouragement to some of the interests handling California oil properties and a strong effort is being made to interest the public in oil leases, and in developing companies. There is glib talk of gushers, dusters, drills, rigs, pumps, and casing by many promoters who really do not know whether oil is sold by the bale, bag, or bushel. The climax of the rubber hysteria in London seems to have been reached and the wild markets of the past two or three days seem to have resulted principally from the desire of some pessimist to count his profits in real money instead of on paper. The Copper Producers' Association figures for March, made public April 10, showed 120,066,000 lb. production; 62,844,000 domestic consumption and 40,584,000 exports. The surplus increased 16,638,000 lb. This added to the stock on hand makes 123,825,992 lb. These figures were a considerable disappointment since it had been claimed that consumption was now at the high rate of 750,000,000 lb. per annum. There were numerous increases in production and the expected larger domestic consumption failed to materialize. The Calumet & Hecla production for March was 12,277,142 as against 11,358,545 lb. Rio Tinto's copper sales during 1909 amounted to 35,496 tons (70,992,000 lb.), from which the net profit derived was £1,209,389 ($5,901,818). The management, which is looked upon as of the highest authority in copper metal circles, says, "The situation for 1910 gives promise of improvement, consumption all over the world being good." The copper conditions abroad are improving, the visible supply in London on April 1 was 111,440 tons, as against 112,730 tons on March 15, and 113,460 tons on March 1. The claim that copper supplies now are larger than ever before in the history of the metal is not taken seriously. Comparing the situation today with that of ten years ago, the statement is made that, at that time, Amalgamated alone had an accumulaion of 300,000,000 lb., while today the accumulated surplus of the world is not more than 50,000,000 lb. in excess of that figure. Alexander Agassiz's successor, as president of the Calumet & Hecla Mining Co., is Quincy A. Shaw, who was elected at a meeting held in Boston this week. Mr. Agassiz's son, R. L. Agassiz, was added to the board of directors. Mr. Shaw is the son of the late Quincy A. Shaw, who, for many years, was Mr. Agassiz's principal associate in carrying the affairs of the big company, which they guided so successfully; while the younger Agassiz, as well as the new president of the company, has been active in the affairs of the Calumet & Hecla for some years. Mr. Agassiz's death is counted a personal loss by every miner in the upper peninsula of Michigan. It is said that he took a greater pride in holding the loyalty and affection of the workers in the mines and in the fact that he never had a strike or even a walking delegate to contend with, than he did in the dividend record of the company over whose destinies he presided. T. L. Livermore, vice-president of the company, has resigned. Mr. Livermore has served the company for twenty-one years and has for some time been planning to retire, but he will remain in active service some months longer to give such assistance as may be needed to his successor. The annual report of the Calumet & Arizona shows an output for 1909 of 37,630,100 lb. of copper, sold at an average price of 13.047c., which compares with 28,050,000 for 1908; 30,500,000 for 1907; and 37,370,000 in 1906. The banner year as to profits was 1907 when the output was sold at an average price of 18.102c. There is a great deal of interest being shown in the results of the diamond drilling being done at Bisbee. Indications are that the life of mines is to be greatly prolonged and the productive area much widened. An assessment, or rather a call, of $1.25 per share is to be made by the First National Copper Co., which operates the Balaklala property in California. The shares of the present company, given in exchange for Balaklala, were issued with $2.50 unpaid and subject to call. It is necessary now to take up or refund some notes and a small outstanding bond issue of the Balaklala company and by making the call as outlined the liabilities can be met without incurring interest charges. A circular was recently received by holders of United Copper from the Western Development Co., a concern which took over the remaining assets of Otto Heinze & Co., who failed after the explosion of a bunch of fireworks in United just before the 1907 panic. The letter conveyed the information that a large number of stockholders had agreed to exchange United Copper for Anaconda share for share, and ended with an inquiry as to whether such a proposition would appeal to the recipient. The response was a unanimous affirmative, coupled with an energetic inquiry as to the possibility of such a move. United Copper's assets are largely an unknown quantity, it has paid no dividends and its prospects are poor. As such an exchange would mean a clear market gain of $20 or $30 per share, the proposal seemed too good to be true; a view evidently held by the officials of the Anaconda, who, promptly and emphatically, denied all connection with any such deal or any other deal looking to the absorption of Mr. Heinze's company. The new Anaconda may develop a wide flung mantle of charity, but of a certainty it will never be extended to cover F. Augustus Heinze or any of his institutions. One particular trait of the Standard Oil Co. and of its affiliated organizations is a long memory, and assuredly Mr. Heinze gave them much to remember. A bill has been introduced in the New York Assembly, intended to curb the pernicious activity of mining promoters, whose ability lies in writing alluring advertisements. The measure will make it a misdemeanor to sell or offer to sell any shares in any mining, oil, or natural-gas enterprise, unless a proper statement shall have first been filed with the Secretary of State, giving both physical and financial details.

General Mining News

ALASKA

The report of the Alaska Treadwell Gold Mining Co. for the month ended states that the 240-mill ran 25 days, 16 hours, and crushed 27,104 tons of ore. Of this 590 tons of concentrate, valued at $37,524, was saved, and $59,414 as free gold. The operating expenses amounted to $64,781 and construction, $8056. The yield per ton of ore milled amounted to $3.77.——At the Alaska Mexican mine, the report for the same period gives the mill run 21 days, 2 hours, ore crushed, 12,397 tons, concentrate saved, 235 tons, valued at $17,748, base bullion, $1940, and free gold, $22,512. The operating expenses amounted to $26,482 and the yield per ton of ore milled, $3.40.

ARIZONA

COCHISE COUNTY

(Special Correspondence).—The adit being driven into Sacramento hill by the Copper Queen company, in the Warren district, has failed to cut the ore anticipated, and raises will be started to prospect the altered ground nearer the surface. At the Uncle Sam a new orebody has been opened on the B level.——Development at the shaft of the Denn-Arizona has been confined lately to the 1350-ft. level where drifts have been started toward the Junction shaft.

Warren, April 9.

Bisbee, Arizona.

Sinking has been resumed in the Briggs shaft of the Superior & Pittsburg Copper Co., at Bisbee. The Junction shaft is now 300 ft. below the Briggs so no trouble is anticipated with the water which was the main drawback in the past. At the Hoatson there is probably more ore blocked out than any other shaft in the district. On the 1200-ft. level the orebody has been opened for a length of 700 ft. by a width of 100; on the 1300-ft. level, 700 by 120, and on the 1400 two sets above the level 175 by 90. About 325 tons per day are being drawn from this shaft which averages 7% copper.——The retimbering of the Oliver shaft of the Calumet & Arizona Mining Co., at Douglas, has been completed and the ore is now being hoisted there. While this work was being completed the company was hoisting about 900 tons per day through the Irish Mag shaft.——The Bisbee Extension Development Co. is now sinking below the 800-ft. level and cross-cutting on the 400.——The Nebraska & Arizona Copper Mining Co. has resumed work on the Morrow & Chamberlain group in the Paradise district.——At the California & Paradise, the boiler and hoist have been installed, and pumping resumed in the shaft.

GILA COUNTY

(Special Correspondence).—The Warrior Development Co. is shipping 105 tons per day of chrysocolla ore to the El Paso smelter. Practically all of the mining operations are confined to the 250-ft. intermediate level stopes and the 300-ft. level.——Three drifts and a raise are being driven at the Live Oak mine and the sinking of the vertical shaft is progressing rapidly. All the drifts now being advanced are on the third level. The two longer drifts are in ore of exceptionally good grade, and of excellent concentrating quality, while the third is in ore averaging about 2.5% copper.——The winze sunk from the fourth level of the Gardner workings of the Superior & Boston mine is 40 ft. deep and has been in ore averaging about 8% copper continuously. Drifts east and west from the winze on the fourth level have been in ore of about the same grade as that found in the winze.—The vertical prospecting shaft being sunk on the Blackbird claim of the Arizona-Michigan property is 140 ft. deep, and is still following a well defined vein containing much iron and manganese between limestone walls. The cross-cut driven south from the Telfair shaft on the fifth level is 700 ft. long, and still in shale, with very little mineral in evidence.——The cutting of a station at the 660-ft. level of the Williams shaft on the National Mining Exploration property is now under way.

Globe, April 9.

MOHAVE COUNTY

Two shipments were brought in recently from the Gold Road and Tom Reed mines, which establish new records for these properties. The Gold Road output, consisting of nearly 600 lb. of precipitate, is valued at approximately $25,000, and represents an 11 days' run of the 200-ton mill. The Tom Reed sent in 159 lb. of bullion worth about $37,000 which is the result of a 12 days' run in a 10-stamp mill. Flint pebbles, used for fine grinding in tube-mills, have been found along the Colorado river, and during the last few weeks they have been thoroughly tried out in both the Gold Road and Tom Reed mills giving excellent results.

PINAL COUNTY

The Calumet & Copper Creek M. Co. has been organized to take over options on 36 claims in the Bunker Hill district held by F. J. and R. Sibley. The property was formerly worked by the Calumet & Arizona M. Co. which gave the options to the Sibleys who have erected a 250-ton concentrator and are now building a reverberatory furnace to treat the concentrate.——The Guggenheim interests have taken over the old Silver Queen mines, near Florence, and a pipe-line to convey oil for fuel to the property is being laid.——The Montezuma and Gold Hill mines, four miles from Florence, have been consolidated and will be operated by the Montezuma Gold Mining Company.

YAVAPAI COUNTY

(Special Correspondence).—The recent discovery in the Little Daisy claim, at Jerome, proves to be the most important find for many years in this district. J. J. Fisher states that the orebody has been cross-cut 81 ft., and the wall has not yet been reached. The ore consists of red oxide of copper, native copper, and considerable glance.——The Jerome-Verde property is to resume development work at once under the direction of Thomas E. Campbell. This property adjoins the United Verde Extension group, on the east.

Prescott, April 8.

The Mildred Gold Mining Co. is erecting the 10-stamp mill which it removed from the Humboldt claim to its group in the Weaver district. There are two shafts on the property

which are to be connected on the 150-ft. level, and the mill is so placed that the ore may be trammed by gravity from either. Dan B. Genung is manager.——E. L. Bartholomew and James Rees, operating the Devonshire mine in the same district, have opened a 2-ft. shoot that assays $60 per ton. Arrangements for the installation of a compressor and air-drills are under way.——New machinery has been installed at the shaft of the Arizona Bonanza Mining Co., and sinking resumed at a depth of 140 ft. There are four claims in the group which is situated about three miles from McCabe. ——Arrangements have been made to ship from 100 to 150 tons of ore per day from the United Verde mine to the Humboldt smelter. The United Verde ore is an excellent flux for the ores of the Humboldt district.——Unwatering of the Triangle mine, at McCabe, temporarily stopped a few weeks ago on account of litigation, has been resumed and the property will be thoroughly sampled. The shaft is down 400 ft. with several hundred feet of drifts run on the ore.

YUMA COUNTY

A gasoline hoist capable of hoisting from a depth of 1000 ft. has been installed by the Inland Copper Co. at its property near Planet, and a contract let to sink the shaft from the 150 to the 250-ft. level.

CALIFORNIA

INYO COUNTY

W. W. Smith has succeeded Clarence S. Beall, who resigned recently, as manager of the Casa Diablo mine, near Bishop. The shaft is now below the 250-ft. level, and the main adit is expected to cut the Granite Mountain vein in a short time.

KERN COUNTY

(Special Correspondence).—The Red Dog mill, at Johannesburg, has installed a concentrator for treating tungsten ore. Christensen & Dolbear have found placer tungsten on a number of quartz claims in the Stringer district and have treated ore at the mill producing tungsten concentrate to the value of $800.——The Atolia Mining Co. is about to install an electric light plant and is contemplating the erection of a stamp-mill. The company has now about 30 men working on its Churchill property where a good vein of scheelite yielding a high-grade tungsten has been opened. ——Len Cunningham has the contract on the new adit of the Consolidated Mining Co. About 100 ft. has been completed.——The Sunshine Leasing Co. has completed a considerable amount of dead work and is now blocking out an orebody.——Shipsey & Dickinson have a lease on the Little Butte but have done chiefly dead work up till now. The ore on the Little Butte and on the Butte occurs in lenses. These are rich and easily worked but are far apart. Benson & Bryan, who are working a lease on the 200-ft. level of the Butte, have struck a large orebody which they are stoping. Watchman & Watchman, leasing on the 160-ft. level, milled 6 tons this week which yielded $300. Montgomery & Norton sent 3 tons to the mill the other day which plated $84 per ton.

Randsburg, April 10.

NEVADA COUNTY

(Special Correspondence).—The copper mines in the Spenceville district are again attracting attention. Local capitalists are developing a number of properties near the Iron Mountain, which was taken over last year by the United States Smelting, Refining & Mining Co. In addition to copper the ores contain considerable gold.——E. L. Fields and associates are arranging for the resumption of activities at the Gold Mound. New machinery will be installed immediately.——The shaft at the Empire is down 3650 ft. and the ore showing is said to be good.——The hoist at the Mountaineer has been completed and hoisting is under way from the 400-ft. level. It is expected to have the tramway completed within ten days.——It is understood that the Central Consolidated will commence sinking soon. A new skip and 1100 ft. of iron cable have been installed. C. N. Bailey is manager.

Grass Valley, April 11.

The raise from the adit at the Blue Lead mine, at Relief, cut the gravel when up 30 ft., and drifts have been started toward the rims of the channel. The gravel is the blue type and pans well. J. O. Jones is manager.——Work has been resumed at the Mayflower mine, on Canada hill, and the old adit, which is in 2000 ft., is being retimbered and a shaft is to be sunk at its face. The mine was formerly a good producer and supplied ore for the 20-stamp mill on the property.——The force at the Giant King mine, near Washington, is to be increased and the mill started about the first of May. Throughout the winter the company has been blocking the ore cut by the adit last fall and now has several hundred feet of backs ready for stoping.

PLACER COUNTY

F. B. Norton, superintendent of the Crandell property, has sunk three 60-ft. shafts on the vein opening some fair ore.——The raise at the Red Sea mine, in the Auburn district, has opened the channel showing the gravel to be a portion of the old blue lead.——A large body of gravel has been opened in the Home Ticket mine, near Last Chance. ——Work is to be resumed this spring on the Imperial property.——At the Rawhide the adit is in 1500 ft., the face having a vertical depth of 900 ft. Portions of the vein exceed 70 ft. in width.

SIERRA COUNTY

(Special Correspondence).—The Rainbow has opened a rich shoot of ore in the main adit. It runs from 10 to 30 in. wide, with ore assaying from $50 to $5000 per ton. Some of the ore is exceptionally high-grade. The rich stuff is being sacked for shipment to the Selby smelter, while the low-grade is being treated at the 10-stamp mill.——The Oakes claim has been bonded by Homer Gould and E. Pegg, of Downieville.——The Eastern interests controlling the Dreadnaught, Rose, General Sherman, and other properties have taken a bond on the Gold King at Alleghany. Development will be started immediately under charge of Daniel McGonigal.

Alleghany, April 11.

The Oriflamme mine at Alleghany has been sold by F. B. De Lanney and George W. Taylor to the Oriflamme Mining Co., of which C. C. Ward is manager.——The drift at the Wonder mine has cut quartz that pans well and the management expects to open the shoot within a short distance. ——A raise to the surface has been completed at the Sixteen-to-One securing better ventilation and a shaft commenced that will cut under the rich ore opened last spring. ——The drift at the Twenty-One is in a good grade of milling ore.——A new compressor is to be installed at the Cleveland mine.——Work is to be resumed at the Oakland mine, in the Gold Lake district, in a few days. The company opened a good shoot of ore last summer and erected a small mill.——A shaft is to be sunk 100 ft. on the shoot at the Standard mine in Sailor ravine.

SHASTA COUNTY

At a recent meeting of the officials of the Shasta County Farmers' Protective Association and the Balaklala Copper Co., at Redding, it was agreed upon that the smelting company would install the Cottrell process in its plant instead of building a bag-house as the Mammoth company is doing.

TRINITY COUNTY

(Special Correspondence).—In the Indian Creek district D. C. Dedrick has just made a satisfactory clean-up on the Texas Jack quartz mine.——Morris Brothers & Fields' are washing gravel on their claims.——Collin Brothers are preparing to resume operations on their Spring Gulch property and about to run some ore through their mill for J. M. Briscoe.——F. O. Hollingsworth, superintendent of the Calmich mine, at Deadwood, has gone to the Yellow Jacket mine, in the East Fork district, and taken a force of six men to commence operations under an option held by M. R. Bacon, of Michigan. This property has been idle for some time.——The lessees on the Gifford mine, in the Eastman Gulch district, have struck some rich ore averaging $5 per lb.——Leas & Nicholson, lessees on the Brown Bear mine, at Deadwood, have a fine orebody with over 100 ft. of backs. The Brown Bear company is preparing to start up the mill.——The Calmich company is install-

ing a compressor and as soon as this is completed will start the mill.——In the Weaverville district the Testy Brothers, Hupp Brothers, Armentrout, and La Grange placer mines are all running on full time, but present indications are that the water season this year will be short as the snow on the mountain is nearly gone.

Weaverville, April 11.

TUOLUMNE COUNTY

(Special Correspondence).—C. H. Thomas, acting for the company which recently acquired possession of the Providence mine, has put a small crew of men at work repairing the shaft and making other preparations for underground operations on a large scale.——Driving each way from the bottom of the shaft, 115 ft. deep, is now in progress at the Yrma mine, near Algerine.——The new shaft at the property on Indian creek recently bonded to L. B. Harris, of San Francisco, has reached 60 ft. and is in good-grade ore. ——A contract has been let for sinking the shaft at the Reed mine, near Big Oak Flat, an additional 100 ft. A hoist was lately installed.——An 8-hp. gas-engine is being installed at the Ida Klein mine, near Stent, and unwatering will begin soon.

Tuolumne, April 11.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—The Conqueror Mining & Milling Co., operating the Conqueror mine on Covode mountain, in the Georgetown district, will shortly start work in the construction of a 100-ton concentrating plant. W. S. Pryor is manager.——Since the Ocean Wave vein was intersected by the Capital adit, 6000 ft. from the portal, it has been driven through for 30 ft. The ore taken averages $16 per ton gold.——The new compressor plant at the Bellevue-Hudson, was put in operation last week, and work is under way sinking a 500-ft. shaft from the Rochester adit level.——The adit at the Lombard mine in the Alice district has intersected the vein 200 ft. under the upper workings, opening a good grade of milling ore.——On the Elliott-Barber lode operated by the Tanquay Mining Co. a body of ore 3 ft. wide has just been cut in the heading of the lower adit that assays from $10 to $17 per ton in gold.

Idaho Springs, April 9.

GILPIN COUNTY

(Special Correspondence).—Work was resumed this week in the advance of the Newhouse tunnel, two shifts being employed. The next vein to be reached is the Prize, a former heavy producer. It will be necessary to drive 1000 ft. before the Gunnell vein is intersected, which is the proposed objective.——A Rand 15-drill compressor of the Imperial type has been installed at the Topeka mine in Russell district.——The shaft of the Quaker City mine on Quartz hill has been unwatered to the 150-ft. level.——At the London mine in the Twelve-Mile district, a streak of ore has been cut that is from 8 to 12 in. wide and assays 7 oz. gold, 53 oz. silver, and 4% copper. W. R. McLeod and W. S. McConnell are operating under lease.

Central City, April 9.

LAKE COUNTY

At the Gold Basin property in the Leadville district the lessees are stoping on the 350-ft. level and shipping ore that averages about one ounce gold and eight or ten ounces silver per ton.——The Cleveland and Vinnie shafts of the Monarch Mining Co. continue to be the most productive of the district producing 75 tons per day. A new pump has been ordered for the Cleveland shaft and will be installed about the first of May. The Monarch shaft of the same company is to be unwatered this summer.——Lessees have resumed work on the Carbutt mine and are now sinking the shaft.——The Siwatch adit in Sugar Loaf mountain is now in 400 ft. and the management expects to complete the work at the rate of 200 ft. per month with the new compressor and drills recently installed.——The Western Mining Co. has installed a new 1000-gal. pump at the 1000-ft. level of the Wolftone shaft.

OURAY COUNTY

The Colorado Smelting Co. has announced that its plant at Ouray will be ready to blow-in by July 1, and that the company will commence receiving ore in a short time to insure a large supply when the furnace is ready for operation. Arrangements have been made to treat the Bright Diamond and Newsboy ore at this plant.——Operations are to be resumed at the Genessee mine in the Red Mountain district about May 1. F. M. Jackson is shipping $100 ore from the Wedge mine which he is operating under lease. ——In the shaft of the El Mahdi mine a new shoot has been opened that has the appearance of developing into a good body of shipping ore.

TELLER COUNTY

The Elkton Consolidated Gold Mining Co. of Cripple Creek declared the regular bi-monthly dividend of 1c. per share and an extra dividend of ½c. per share payable April 24. This will bring the total dividends paid by the Elkton company up to $2,554,460.——Work at the E. Porter mine on Gold hill has been resumed by a number of lessees and the mine will soon be on the shipping list.——Frank Seeley, of Victor, operating a lease on the Favorite property opened a shoot of ore that assays from $20 to $140 per ton, when driving a drift on the 500-ft. level of the Logan shaft.—— The Vindicator Consolidated Gold Mining Co. of Victor has declared its regular quarterly dividend of 3c. per share payable April 25.——A shoot of high-grade ore has been opened in the stope from the east drift on the 350-ft. level of the Henry Adney mine on Beacon hill. This is the second rich shoot cut within the past three weeks in this property.—— The Gaylord mill shipped a 24-lb. retort to the United States mint at Denver recently which represented the clean-up on the run of 1000 tons of low-grade ore from the Jerry Johnson mine.

IDAHO

IDAHO COUNTY

At the Crackerjack mine in the Buffalo Hump district 10 stamps are dropping steadily and 10 more will be started in a short time. In the mine both the winze and raise from the main level are in ore that assays $60 per ton.——F. W. Bradley has secured an option on Harmon & Morrow's Lone Pine group in the Ten Mile district. The recent discoveries of high-grade gold ore in this district has caused considerable excitement and a number of claims have been staked in the past month.

KANSAS

CHEROKEE COUNTY

(Special Correspondence.)—A mill is under construction in the Galena camp by the Mess Mining Co. which will have a capacity of 200 tons.——A company working on the Templar land south of Galena has opened a good deposit. The ore proved so rich that it sold at $8 per ton in the rough.——The Baxter-Quapaw camp is more active than it has been for some time. Old prospectors are increasing their workings and new ones are beginning operations. The Red Wing made a turn-in last week after being reopened, and has the same run of ore extending across its workings as is found in the White Eagle.——One of the largest sales of ore ever made in the Baxter camp was made last week from the Okla mine, consisting of 6 large cars bringing approximately $8.——The Old Abe mine will be started this week and the large amount of underground development at this mine will be sufficient to supply the mill continuously.

Galena, April 11.

MISSOURI

JASPER COUNTY

(Special Correspondence).—The capacity of the Alabama mine Porto Rico has been increased by the installation of a new 75-hp. motor. This plant is operated entirely by electricity, a 100-hp. motor being used to drive the mill and two of 37 hp. each to drive the hoisting apparatus. A 20-ft. face of ore is being worked at a depth of 185 ft.——The Bradford-Kansas City mine famous for containing one of the largest open pits in the field, has discovered a lower run of ore below the old workings at 187 to 211 ft.——The Mandarin in the south Joplin field has now become a heavy producer after a long period of prospecting.——A rich dis-

covery has been made on the Old Cardinal ground by Frank Watkins. A stope of ore 25 ft. thick is available all over the tract.——The old Bumblebee property southeast of Joplin, one of the famous mines of a few years ago, is being drained and will be opened as soon as possible. A medium sized concentrating plant is on the ground.——The Millard lease in the Porto Rico camp was last week sold to New

Zinc Mining and Smelting Centres.

York interests for $25,000 and preparations are being made by the new owners for the immediate development of the property and the enlargement of the mill.——The St. Paul company, one of the largest land owners of the district, has started drilling on land south of Joplin and has put down 20 drill holes, 18 of which showed ore assaying from 2 to 6%.——A new mill has been started at Four Corners by J. L. Babson. A large amount of development work was done while the mill was being erected and the ore on the dump is sufficient to keep the mill busy for some time.

Joplin, April 9.

MONTANA

BROADWATER COUNTY

(Special Correspondence).—The Ohio-Keating Gold Mining Co. has just made the final payment on its property in the Radersburg district. It is also announced that the control of the Ohio-Keating has been taken over by the Radersburg Consolidated Mining Co., a new corporation formed under the laws of South Dakota, with a capitalization of $1,000,000. It is explained that the new company was organized as a holding corporation, and in addition to holding a majority of the stock of the Ohio-Keating holds control of the Manhattan-California Gold Mining Co. which is reported to own 400 acres in the mother lode district of California near Placerville. It is said that both the Montana and California companies will immediately begin mining and shipment of ore under the new management. ——The Radersburg district will likely have railroad connection in the course of a few months. The mine operators have taken the matter up with the Northern Pacific company with the result that two surveys are now being made to determine the most feasible route.

Radersburg, April 8.

SILVERBOW COUNTY

An accident to the hoist at the Neversweat mine in Butte wrecked the engine and killed the engineer. One cage was dropped into the sump and the other hung up between the 1800 and 1600-ft. levels. The accident has thrown 300 men out of work and it is thought that the mine will be shut down several months to repair the damage which amounts to nearly $100,000.

NEVADA

CHURCHILL COUNTY

(Special Correspondence.)—The Nevada Hills and Fairview Eagle companies have consolidated, and in future both mines will be operated under one management. It is planned to erect a large milling plant. Water rights sufficient for all purposes have been secured, while electric power will be secured from the United States Government power plant which will be erected at Fallon, in connection with the Carson-Truckee irrigation project. Nevada Hills is opening good ore on the 400 and 450-ft. levels, and two or three carloads of high-grade are being sent to the smelters each month.——The Nevada Wonder management announces that work on the power line will soon commence and that a milling plant will be erected in the summer.—— Two 40-hp. traction engines have been ordered for traffic purposes between Fallon and Wonder.

Fairview, April 9.

CLARK COUNTY

The lower adit of the lessees on the I. X. L. property in the Searchlight district is in 180 ft. and a sample taken across the 30-in. vein at the face gave an assay of $40 per ton.——A contract has been let by the King Bee Mining Co. to sink a 5 by 7-ft. shaft on its property in the Eldorado Canyon district.——George Bergman is to add three stamps to his mill which is now crushing the ore with one Huntington.——Operations are to be resumed at the Rich Hill mine in the Eldorado Canyon district.

ESMERALDA COUNTY

The Weber-McLaughlin lease on the Booth property in the Goldfield district, cut 6 ft. of milling ore and a raise has been started to see if the shoot will develop into ore of shipping value. The Lind lease cut 4 ft. of quartz in the dacite and development work will be started on this later.——Development on the 500-ft. level of the Combination shows the orebody recently opened there to be between 8 and 10 ft. wide. On the 280-ft. level some rich stringers have been found which the management believes to be the continuation of the rich orebody opened in the upper levels of the mine.

LINCOLN COUNTY

At the Flagstaff group 11 miles north of Pioche several fissures of silver-lead-copper ore have been opened while doing the assessment work on the claims. Over a ton of ore containing considerable chloride has been hauled to Pioche.——William Fanchini and Joseph Vietti who have been operating the old Delamar mill under lease are crushing good ore and expect to clean about $5000 worth of amalgam off the plates.——The Gold Chief Mining Co. is tearing down a number of cyanide tanks at the mill and will remove them to the Panaca mine. E. L. Gluyas is in charge of the work.

LYON COUNTY

The preliminary work on the Mason Valley smelter has been delayed on account of the recent illness of Jules La Barthe who was to have started operations in March. It is now thought that the grading will be started some time this month and the foundations will be built in June and followed immediately by the installation of the machinery. In the mine work has been started on the 600-ft. level blocking out ore, the richest so far discovered being found on this level.——The grade for the Nevada Copper Belt railroad is completed to Smith valley and work has been started on the remaining eight miles to the Morningstar mine.

NYE COUNTY

The directors of the MacNamara Mining Co. operating in the Tonopah district declared a dividend of 2½c. per share amounting to $18,362 payable May 2. There will still be a large balance in the treasury which it is reported will be distributed in a short time. The raise from the 300 to the rich ore opened on the 275-ft. level has been completed and the drifts on the vein are being advanced more rapidly. The company is shipping about 250 tons of ore per week. ——At the Montana Tonopah considerable cross-cutting has been done the past week in the Martha and Triangle veins opening good ore in both places. Work in the mine is well ahead of the mill which is dropping 40 stamps continuously. ——The work at the Tonopah Belmont is mainly concentrated on the big orebody first opened on the 1100-ft. level. Drifts on this are being advanced on the 900, 1100, and 1160-ft. levels and a winze has been started at the 1160. This is down 15 ft. showing the vein to be over six feet wide and of good milling grade.——The Tonopah Extension report for March shows 15 bars of bullion valued at $17,250, 14 tons of sand concentrate valued at $500 per ton,

and 20 tons of slime concentrate valued between $250 and $300 per ton shipped. The ore from the mine is being mixed with a much lower grade from the dumps bringing the general average below that mined.——At Round Mountain a number of lessees are operating on the Blue Jacket property and shipping good ore.——After a long period of idleness the Elspass mill has been started on 750 tons from the Morrin & Perrine lease.

STOREY COUNTY

The report of the superintendent of the Silver Hill mine in the Virginia City district shows that a $3000-bar was shipped to the Carson City mint as the result of crushing 400 tons of ore. The tailing which assays high in gold and silver has been stored and will be sold in the near future. Raises have been started in ore on the 100 and 150-ft. levels.——The new transformer for the auxiliary pumping plant at the C. & C. shaft has been installed at the 2350-ft. station and the power has been turned through the motors which drive the new pumps. The old Cornish pump will now be pulled out of the shaft and the sinkers lowered. ——Company work has been discontinued in the Overman mine and leases let on the mine workings.——The 20-stamp mill at the Butters property has been started one day per week on ore from the Comstock Phoenix mine though the cyanide plant is being worked continuously on pulp from the tailing reservoirs. Later the mill is to be run on ore from the leased workings of the Monte Cristo and Collar-Potosi mines.

WHITE PINE COUNTY

James McDonough and E. Pursel have obtained a contract to supply the Steptoe Valley Mining & Smelting Co. with 200 tons of silica and are working at their claims across the valley from Ely. The company uses from 200 to 300 tons of silica per month.——Fred Becker and H. W. Lowrie have obtained a lease on the tailing from the plant of the Nevada United Mines Co. and are installing a cyanide plant to handle the material.——The officials of the Eureka & Palisade railroad have given out a statement that the road which was badly damaged by the heavy storms the past winter will not be rebuilt and plans are now being considered for a broad-gange line from Ely to Eureka.——A complete 10-stamp mill for the Amalgamated Nevada Mines Co. has been landed at Ely and will be hauled to the company's property at Blackhorse. The plant will be erected near the Mabel and San Pedro mines which were recently acquired at a sheriff's sale for $102,000.

NEW MEXICO

EDDY COUNTY

The H. C. Hammond well near Dayton, which was brought in a short time ago, is now producing from 20 to 40 bbl. of oil per day. Pumping has been stopped temporarily on account of the lack of storage facilities, but two large cement reservoirs will be completed in a few days when operations will be resumed. The well of the Giant Gas & Oil Co. in the same district is down 750 ft. and is expected to cut the oil-bearing strata any time.

GRANT COUNTY

Over 3500 ft. of development work has been done at the Cleveland group eight miles north of Silver City opening several veins of zinc carbonate ore. The main vein is 40 ft. thick and assays from 20 to 40% zinc with a small amount of silver and gold. There are some 5000 tons of ore on the dump and arrangements are being made to erect a mill at the property.——Considerable work has been done at the Red Cross property which adjoins the Cleveland and a good grade of ore opened.

OREGON

BAKER COUNTY

The drift on the lower level of the Climax mine in the Cracker Creek district opened the rich shoot of ore that was cut in the upper level several weeks ago, giving the company 300 ft. of backs.——Considerable work is being done on the Listen Lake property near Sumpter and a good body of copper ore is being opened at a depth of 300 ft. Should this prove to be a good smelting ore it will go a long way toward settling the problem of obtaining sufficient ore of proper grade at the Sumpter smelter.——A number of prospects are being opened in the New Eldorado district which is a portion of the Greenhorn and Middle Fork districts.

PHILIPPINE ISLANDS

A recent sampling of the San Mariclo mine in the Paracale district resulted in the average of $26 per ton. The company started its 20-stamp mill the latter part of February and is now preparing to build a small tram to convey the concentrate to the coast and supplies to the mine. Monthly shipments of bullion will be made to Manila and of the concentrate to some of the Pacific Coast smelters. In the mine a station has been cut on the second level and a cross-cut started toward the vein. A. W. Cole who was formerly superintendent of the Benguet Consolidated is now in charge of the mill.——The East Batan Coal Mining Co. is producing 6000 tons of coal per month and is preparing to install machinery that will greatly increase this output. It is estimated that the company has in sight enough coal which sells for $3.25 per ton at the mine to prodnce 300,000 tons annually.

TEXAS

EL PASO COUNTY

(Special Correspondence).—A streak 18 in. wide that assays more than 90 oz. silver is being developed in the Tama mine in the Quitman mountains. This mine is being worked by John Moffitt under bond and lease from Thomas O'Keefe.——An adit that was driven at the Lula B mine in the Quitman district cut the vein a few days ago. The mine is owned by T. McKinney and William Crosby of El Paso.——A wide pay streak of high-grade sulphide that assays well in gold and silver was opened a few days ago in one of the mines of the Little Lightning group situated near Lasca. These mines are producers of ore that assays from 12 to 18% copper, several cars of which have been shipped to the smelter at El Paso. All of this ore was taken from a 45-ft. drift at the bottom of a 25-ft. shaft. The group is owned by John C. Gilcrease.

Lasca, April 9.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—A few more drills are being started at the Le Roi mine in the Rossland district which will no doubt make heavier ore shipments in the near future.——Harris Brothers of Rossland have sold another property near Hazelton that they are interested in for $35,000.——It is announced from Ottawa that the Dominion Government has decided to make a general codification of the mining laws of Canada, which should do away with the present confusing state of affairs. Committees have been appointed to start this important work.——The Blue Bell mine in the Nelson district has been closed down. This is a low-grade zinc-lead property which has been concentrating about 900 tons of ore per week, most of which has been taken from above the adit level. It is known that there is a large tonnage below this level, but the mine at present is not equipped to handle this ore economically.——Several good discoveries have recently been made in the Slocan district. In addition to the find of good ore at the Rambler Cariboo, a body of galena averaging approximately 55% lead and 200 oz. silver per ton has been opened on the Hidden Treasure claim of the Slocan Star group.——At Coleman the McGillivray Creek Coal & Coke Co. has its new tipple in operation and will double its output. Electric fans have been installed and work on the new adit begun.——The British Columbia Copper Co. treated about 45,000 tons of ore in February and made a net earning of approximately $41,000. Copper was produced at a cost of 7.88c. per lb., which included all costs of development work at the mines. The company is making preparations to install a tram from the No. 7 mine to the mill-site at Boundary Falls, where preparatory work is being done toward the erection of the concentrator.

Rossland, April 9.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. V. Winchell is at New York.

Lionel Lindsay is at San Francisco.

James Douglas is at Bisbee, Arizona.

R. H. Channing was in San Francisco.

Jesse J. MacDonald is in San Francisco.

Courtenay De Kalb has gone to Arizona.

F. Lynwood Garrison is in San Francisco.

C. W. Purington is at Brookline, Massachusetts.

Corey C. Brayton is in Mexico examining placer ground.

H. F. A. Rieblino is in Iowa examining a fire-clay property.

S. F. Shaw has been making an examination in Sonora, Mexico.

L. J. Hohl has gone to St. Gali, Switzerland, for a few months' trip.

John W. Mercer landed in New York, returning from Europe, April 8.

Forest B. Caldwell is leaving Santa Lucia, Sinaloa, for Woodland, California.

A. M. Yonge has moved to Richmond, Virginia, from San Mateo, Costa Rica.

S. F. Brethertон is in Plumas county, California, on professional business.

George J. Young of the Mackay School of Mines has been visiting Freiberg, Saxony.

E. McCormick has returned to Calumet, Michigan, from an extended visit to the East.

Robert Scott has returned to San Jose from a visit to the quicksilver mines of Morelos, Mexico.

C. Barnes Hoadly, of Searchlight, Nevada, is making an extended tour through the mining districts of Mexico.

Bernard MacDonald is general manager for the Vetа Colorada M. & S. Co., at Villa Escobedo, Chihuahua, Mexico.

L. G. E. Bignell, sales manager for the Denver Engineering Works Co., has returned to Denver from Salt Lake, Utah.

I. H. France is in Chalchihuites, Mexico, making an examination of the National Smelting property for the C. L. Constant Company.

John Peray, chairman of the Board of Directors of the Palmarejo & Mexican Gold Fields, Ltd., is on his way from London to Chinipas, Mexico.

Hal. M. McLaughlin is now general manager of the mines and smelter of the Central Chili Copper Co., Ltd., at Panulcillo, Coquimbo, Chile.

Donald F. Irvin is leaving thet Standard Con. M. Co., at Bodie, California, to accept a position with the Vulture Mines Co., Vulture, Arizona.

Charles H. Shamel is delivering the annual course of lectures on mining law to the senior law class and the mining students of the University of Washington at Seattle.

OBITUARY

Thomas F. Walsh, who died at Washington, D. C., April 8, was one of the best known mining men in America. He was born in Ireland in 1851, and educated in the public schools. He came to America at the age of 19, going almost directly to Colorado and taking up mining. His first success was at Leadville, and he worked in the Black Hills of South Dakota, but it was in the San Juan that he won fame and fortune. Mr. Walsh will probably be best remembered as the discoverer of the Camp Bird mine. His success was not fortuitous but was founded on hard work and intelligent study. As is well known, the Camp Bird had been located, worked, and abandoned before Mr. Walsh was attracted to it. His predecessors had looked only for the particular type of silver ore found in adjacent properties and had overlooked the possibilities of the thin streak of quartz which since has yielded so many millions of dollars in gold. He had the foresight and patience to examine the whole vein, and the business acumen to properly equip and develop the mine after he had obtained possession. After selling the Camp Bird, Mr. Walsh lived at Washington, D. C., and took an active part in public affairs, though he never, in pleasing contrast with other millionaires, bought his way into political office. As commissioner to the World's Fair in Paris he came into contact with King Leopold, of Belgium, and he was influential in promoting development of the mineral resources of the Congo. The Trans-Mississippi Congress, the Irrigation Congress, the American Mining Congress, the Conservation Commission, have all had his help in their work. He was a liberal and consistent giver not only of money, but of service and was deeply interested in the mining industry. As founder of the Vinson-Walsh research fund at the Colorado School of Mines, he greatly stimulated the search for, and study of, rare minerals and in this and other directions his influence will work for good long after he, as an individual, has been forgotten. Mr. Walsh represented the best type of the sturdy pioneer and prospector. He was a likeable companionable man, and to those who had known him as a miner, he remained always the same friendly 'Tom Walsh', and was genuinely glad to do so.

Franklin R. Carpenter, who died April 1, at Chicago, was widely known as an expert in smelting. He was born at Parkersburg, West Virginia, in 1848, and graduated at the University of Ohio at Athens. He spent some years teaching in Colorado and South Dakota, and it was while serving as Director of the South Dakota School of Mines that he first seriously took up the problems of pyritic smelting, the field in which he was best known. He built the Deadwood & Delaware Smelting Works, at Rapid City, making them the first commercial success of pyritic smelting. In 1900 he returned to Colorado where his services were in large demand in consulting work. He built the Rocky Mountain Works at Florence, and the Clear Creek Mining & Reduction Works at Golden, operating the latter, in connection with the Saratoga mine, for some years. He found time not only to experiment and to operate, but to contribute frequently to the technical press and in determining the limitations of pyritic smelting did much excellent work.

PUBLICATIONS RECEIVED.

Any of the books noticed in these columns are for sale by, or can be procured from, the Mining and Scientific Press.

The Innoko Gold-Placer District of Alaska, with accounts of the Central Kuskokwim Valley and the Ruby Creek and Gold Hill Placers. By A. G. Maddren. U. S. Geol. Surv., Bull. 410. Pp. 83, ill., index, maps. Washington, 1910.

An excellent general account of a region which will attract much attention this summer. Prospectors and others intending to enter this territory should have a copy, which, as usual, may be obtained free on application to the Director, U. S. Geol. Survey. Washington, D. C.

Report of the Governor of the District of Alaska for 1909. By W. B. Hoggatt. Pamphlet. Pp. 69. Washington, 1909.

It is recommended that a law be enacted defining the length of tunnel or depth of shaft which shall be required as assessment work and also requiring that such work shall be done within 90 days after location. It is also suggested that association claims should require eight times the work done on one claim. These changes, it is held, would throw open vast areas of placer ground now held for speculative purposes under location by power of attorney or in association claims.

COMMERCIAL PARAGRAPHS

S. B. Gregory has been appointed Pacific Coast manager for the Arrow Electric Co., of Hartford, Connecticutt, with offices at 629 Howard street, San Francisco.

The American Machinery & Export Co., of Tientsin, China, announces that it is prepared to accept agencies for American mining, milling, and railway machinery in North China. Only American agencies will be accepted by this firm, as the handling of American business by British and German firms has proved unsatisfactory in practice. Affiliated with the firm are six American engineers, and it is prepared to advise on plant required and to design and erect power and reduction plants of any nature. Communications should be addressed to the manager, E. K. Lowry, Tientsin.

The Mines Management Company, 40 Wall street, New York, has been formed for the purpose of furnishing to bankers, brokers, underwriters, and syndicates, reports and appraisals on mining stocks or properties. This company will also undertake the organization or re-organization and consolidation of mining properties, and it is its further purpose to undertake the management of mines and to supply engineeering, managerial, and other services to those interested in mining. This company will maintain a New York office having connections with well known consulting engineers in North and South America. In many respects, the organization will follow closely that of the well known firm of John Taylor & Sons, of England. The directors of the Mines Management Company are Philip W. Henry, president; Edwin C. Holter, vice-president and general counsel; Marvyn Scudder, secretary; W. B. Devereux, Jr., treasurer, and H. A. J. Wilkens. F. A. Provot is consulting engineeer. Among the engineers associated with the company are J. Gordon Hardy and E. Coppee Thurston. At present the Mines Management Co. is managing the Achotla mine, one of the Ortiz properties in the State of Guerrero, Mexico. The mine is 8 miles north of the Balsas river, and 50 miles from the terminus of the Guernavaca branch of the Mexican Central railroad. It is producing gold-silver bullion which is sold in Mexico City.

CATALOGUES RECEIVED

The C. O. Bartlett & Snow Co., Cleveland, Ohio. Catalogue No. 31. 'Soft Mud Brick Machinery, Low Pressure Brick Dryer, and Automatic Pallet Conveyor'. Illustrated. 6 by 9 inches. 32 pages.

Trojan Powder Co., New York. A little booklet setting forth the advantages of Trojan powder and containing much of interest to users of high explosives. Illustrated. 4 by 9 inches. 20 pages.

T. H. Proske, Denver, Colorado. Catalogue showing the salient features and advantages of the Ajax Drill Sharpener. It contains a great deal of information that everyone using rock-drills should have. Illustrated. 6 by 9 inches. 20 pages.

Williams Patent Crusher & Pulverizer Co., St. Louis, Missouri. General catalogue showing crushing, pulverizing, granulating, and shredding machinery. An interesting installation of Williams machinery has recently been made at Cananea, Mexico, where Colonel Green, of Cananea Copper Co. fame, has a stock food plant of from 2 to 3 tons per hour. Illustrated. 10 by 13 inches. 62 pages.

L. Vogelstein & Co., give the following figures of German consumption of foreign copper for the months January and February, 1910:

	Tons.
Imports of copper	29,465
Exports of copper	1,095
Consumption of copper	28,370

as compared with consumption during the same period in 1909 of 23,019 tons. Of this quantity 26,563 tons were imported from the United States.

EDITORIAL.

SYMPATHY from the entire profession goes out to Mr. D. W. Brunton on his distressing automobile accident near Fort Collins. We are glad to report that he is resting easily at the hospital in Denver and recovering as rapidly as could be expected.

RAILWAY building is active in the Northwest. The Great Northern has already awarded contracts for a track over Hope mountains on a line from the Boundary district of British Columbia to the Coast. The Canadian Pacific is to continue its line from Midway to Pentiction and is expected also to build over Hope mountains to Vancouver.

CONGO COPPER production has been much discussed and tales as to future enormous outputs have been widely circulated. Rapid progress is undoubtedly being made as is instanced in the order just placed with the Allis-Chalmers Company by the Union Minère du Haut Katanga for a crushing, concentrating, and smelting plant to handle 900,000 tons yearly.

A TESTIMONIAL DINNER is to be given to Dr. Rossiter W. Raymond at New York, April 30, in celebration of the seventieth anniversary of his birth. His friends are far too numerous and widespread to be more than represented even by the goodly company which will doubtless assemble on this occasion. We shall hope to present later some account of the affair; for the present we extend congratulations and good wishes mingled with keen regret that distance prevents our active participation. There are times when the United States seems over large.

ZINC mining conditions are improving. The effect of the tariff is discussed elsewhere in this issue by Mr. Otto Ruhl. At Joplin the average base price for the seven months before the law went into effect was $40.21. For the corresponding period after, it was $47.74. That difference makes it profitable to re-work old ground and to open additional mines. One interesting example of the new work is that undertaken near Galena by the Boston Mining Company which is re-opening 440 acres previously mined by shallow shafts. It is proposed to install steam-shovels in open pits and to treat the ore in a 600-ton mill; all of which indicates a material change from old conditions. The directors of the new company are conservative business men, experienced in Joplin mining so that the success of the enterprise seems assured.

LAND THIEVES are to have a rest. The famous million dollar appropriation to the Department of the Interior for investigating irregularities in land claims has all been spent and the Special Agents are being furloughed. An additional appropriation of three-quarters of a million has been asked and something doubtless will be granted. There is need for a sufficient force of Special Agents to promptly investigate all claims, but large special appropriations are rarely justified and can even more rarely be used without waste. What is needed in Government service is adequate continuous appropriations rather than alternate periods of feast and famine.

The Coal Miners' Strike

The suspension of work in the bituminous coal mines is only indirectly important to metal miners. The larger plants that are dependent on coal for fuel chance to be mainly so situated as to draw from collieries worked by non-union men. Others accumulated in advance a sufficient stock to last through even a prolonged period of suspension. In Illinois the men have agreed to an arrangement whereby mines supplying coal to the Steel Corporation but not entering the general market, may continue in operation. In Alabama and in the non-union portion of West Virginia and Colorado, the collieries are in full operation. At Joplin gas and electricity are now largely used. In Utah and Montana there is no trouble, and in California, coal and coke are brought in by water. It seems likely that the metal mining industry will feel the effects of the suspension first, if at all, in difficulties over transportation of ore and supplies. The railways use more coal than does any single industry. Directly and indirectly they afford the largest market for bituminous coal and in the last analysis the price paid coal miners is fixed by the railway managers. The needs of the railways and the plans of the railway owners will determine how long the mines remain idle and on what terms the men shall resume work.

It does not seem likely that the suspension of work will continue long. The railways are busy and an unusually large volume of freight is anticipated this summer and fall. Much re-construction is necessary, much is already under way. It is a bad time to have engines dead for lack of fuel. The roads, too, must raise large sums of money for improvements. Mr. James J. Hill estimates that $9,600,000,000 is needed for increasing terminals and sidings alone. In the first quarter of the present year $350,000,000, roughly, has been raised by sale of bonds, advanced by syndicates, or borrowed on notes, for railway improvement in this country. Already it is clear that higher rates than the customary 4 per cent must be paid if these vast improvements are to be made. It is impossible to raise large sums of money except when the country is prosperous, and the astute managers of the big railway systems are not likely to endanger their program to save a few cents on the cost of mining coal.

The United Mine Workers of America is not a new and untried organization. It has a membership of over a quarter of a million men and has capable and experienced officers. It undoubtedly dominates the situation in the central competitive States and in the Southwest. It is weak in the South, in the Southeast, and in the West. In the Middle West and Southwest, however, there is no question as to the ability of the officers to hold the men in line despite the fact that the amount in their treasury is now small. Any thought of breaking the power of the Union by importing non-union men, has long since been abandoned by experienced operators. On the whole, relations between operators and men are cordial. It is only where union come into competition with non-union mines, that the pinch is felt. At first it was thought that the operators of non-union mines in West Virginia would hold out against an increase in wages and the Union officials anticipated an unusually good opportunity to organize the men in these districts. The operators, however, defeated this move by promptly paying the increase asked. As a result the men in non-union collieries, who have contributed nothing to the movement for higher wages, already have the pay for which the Union men are still fighting. It is this sort of a situation, by the way, which not unnaturally, makes Union men vindictive toward the independents.

At present, prospects for settlement on the basis of increased pay to the men seem bright in all districts except western Pennsylvania, Illinois, and Colorado. Even in these areas the advance would probably be promptly conceded if there were no other complications. In western Pennsylvania the trouble arises in connection with the use of safety powder, ordered to be used by the State Mine Inspectors. Both men and companies are willing that the old and dangerous powders should be excluded from the mines, but each wishes the other to assume the extra cost. In Illinois there is a similar difficulty over payment of shot-firers. While according to the State law, these men must be employed and paid by the operators, it has been customary for the men to reimburse the companies. This curious arrangement arose from the fact that the shot-firer's law was passed at the behest of the men at a time when a contract covering mining conditions already existed. As the payment of shot-firers increased the cost of mining and threw the Illinois operators out of line in competition with Indiana and other States, they claimed reimbursement; which the men granted. In both Pennsylvania and Illinois the men say that if the extra cost of safety powder, shot-firers, and other improvements is to be taken from their wages, they will be driven to the unnatural position of fighting every improvement in mining. In Illinois there is a further complication in a threatened advance in freight rates which would still further disadvantage the local operators.

Coal operators can afford to look with some calmness on an advance in the cost of mining which applies to all, but those of each State must necessarily oppose any increase which puts added difficulties in their way and leaves competitors free. In Colorado the trouble is over the fact that only the mines in the northern district are really unionized. The

southern mines accordingly are running as usual, and the northern operators are in danger of losing their trade. Whatever of good will, if any, they may have toward the United Mine Workers, it is not in human nature to sit still and see one's business go to pieces. At least it is not in the nature of Colorado operators. Preparations are accordingly being made to open the mines with non-union labor and the customary force of guards has been hired. There is every reason to anticipate trouble since in Colorado the men take their Unionism seriously. In the end it will be a question whether fighting the strike will give the operators cheaper coal than peaceful payment of the increase asked.

Improvement in industrial conditions has ever come slowly and often through conflict. It is the way of evolution. In the future coal is undoubtedly going to cost more to mine and is going to sell for more throughout the United States, and the United Mine Workers is likely to be an important factor in bringing this about. In the Middle West this organization is already dominant. It is certainly growing in the East, and the affiliation already under discussion with the Western Federation of Miners will give it strength in the West. It will take, however, a much stronger organization than now exists to raise the price of coal to the railways and larger industrial companies, the ones who now buy it cheap. The domestic consumer and the small steam-user already pay their share. They can afford to gaze on the situation with equanimity and speculate at ease on the ways of social progress.

The Earthquake Anniversary

Four years ago last Monday San Francisco experienced the most destructive earthquake of which there is local record. The story of April 18, 1906, and the succeeding anxious days has already been told in the columns of the MINING AND SCIENTIFIC PRESS, as has also the fascinating tale of the rebuilding of a modern city after destruction by quake and fire. The work is now nearly complete. Literally acres of the finest office and business buildings have been built in the burned district and San Francisco is transacting business at the old stand, with larger and better equipment than ever. The earthquake of 1906 was not the first which had been felt here. The files of the MINING AND SCIENTIFIC PRESS contain many interesting references to the shocks of 1865, 1868, and other years, and still older records tell of earth tremors in the days before the gringo came to disturb the peaceful padres and their flocks. Mark Twain, in 'Roughing It', has given an entertaining picture of the earthquake of 1868, as he observed it on Third street not far from the site of our present office. Then as now earthquakes were accepted lightly by Californians as being among the phenomena of nature which make life interesting. Certain it is that earthquakes are not to be prevented. Damage by them may, however, be vastly minimized and to that end much has been done in rebuilding San Francisco.

In 1906 the great loss was by fire following the earthquake and in restoring the city extraordinary precautions have been taken to prevent a recurrence of fire loss. Fireproof construction has been widely adopted and while even the best modern structures can not be expected to remain undamaged in case of a veritable conflagration, experience here as elsewhere has proved that proper building is not only the best preventive of the start and spread of a great fire, but is effectual protection from serious damage by any but the greatest.

Water is, after all, the best means of fighting fire, and in the new San Francisco water is amply provided. To prevent breaking of pipes, the mains are laid with tested sleeve-joints instead of the ordinary bell and spigot joints. As a further safe-guard valves are placed at every street intersection in the district subject to damage and at frequent intervals elsewhere. Any broken pipe can be quickly cut out of the circuit and water passed by other mains. Auxiliary stations with powerful pumps are provided so that water can, if needed, be supplied from the Bay. Mains are carried to the ends of numerous piers and in case of destruction of the ordinary reservoirs and the stationary auxiliary pumps, the mains could still be filled by using fire-boats. The Fire Department is large, well drilled, and well equipped. As a final precaution numerous large street-cisterns have been dug and filled with water. These cisterns are constructed of water-proofed reinforced concrete and are so strongly made that a visiting engineer recently expressed the opinion that they would be shaken bodily out of the ground before being broken. Each cistern is marked by a ring of brick in the asphalt so that even in times of greatest confusion it would be easily found and opened.

By these and other means San Francisco has been made one of the safest cities in the world as regards possible damage by fire, and one of the results of the careful studies made after the earthquake is that it is now possible to mark with great accuracy the areas subject to especial damage in any earthquake region. The reason for the strange freaks of destruction has been found in the character of the foundation. As in Biblical times, the house built on rock is safe. In America but little attention has been paid to studies of this sort though interest in them is increasing. While the subject is of especial interest in California at present, this is merely because it is here that there has been recent damage. The Mississippi Valley in 1812, and the Atlantic Coast in 1886, suffered severely and these and other portions of the country are subject to future damage. On another page are given the resolutions passed at the recent meeting of the Seismological Society of America. It is proposed that a National Institute be founded to carry on research as to the occurrence, causes, distribution, and intensity of earthquakes. Observing stations are to be erected and measurements made which, in time, may even permit forecasting. The terror of storms at sea has largely disappeared now that hurricanes are foretold and sailors are warned. The storms still come but they pass by harmless. It is not too much to hope that in time damage by earthquakes may be similarly minimized.

BY THE WAY.

The following address was delivered before the San Francisco Bar Association recently by Courtenay De Kalb:

In asking me to discuss collectivism tonight, Judge Lindley has asked one who is quite likely to take an opposite view from his own, for the Judge has been brought up in the centres of civilization, while I am essentially a frontiersman.

I think that the experience a man acquires on the frontier necessarily causes him to pay a great amount of respect to the rights of the individual—much more so than in the case of one who has been brought up in the centres of civilization. He comes to appreciate individual iniative and individual prowess on the frontier, and he comes to think less of it where he is not called to depend so much upon the unit as upon the mass. There is such a thing as 'mass action' socially, just as there is chemically: there are changes occurring which are proportional to the products of the masses taking part in it. This is part of the cause of the complexity of social problems, and of the difficulty of determining the course of social evolution as a logical process. There are surprises, inexplicable phenomena—the vagaries due to 'mass action,' which here means the shifting balance of preponderating sentiment at different times. Thus we can not predict; we can not be sure that we or any other men, or body of men who take the task upon themselves, are guiding the forces of civilization in any particular direction. We can study what has been done; we can measure the size and strength of the stones that have been set into the social structure. And it has been borne in upon me that the courts have had more to do with this final work as social artificers than any other single agency. It seems that we can not regard anything in our civilization as essentially fixed until it has been fixed by the courts; until it has been winnowed, and tried, and tested by the judicial safeguards of our civic life. There is eternal shifting, tidal ebb and flow, in the great sea of social existence where men are struggling. In this ceaseless effort, which is an effort always for the future, and therefore progressive, something must line up the flood into a definite current, a consciously purposeful stream; and the force that does it is the force we admit as final, before which we all bow at last, namely, the decisions of the judges. We do not know which way we are going until the courts have decided which way we **may** go.

The decisions of the courts have determined for us, I think, in later years, that the individual is less to be regarded than the mass. I believe that spirit is growing in the West more than it is in the East. That is because the West is feeling the influence of social aggregation after that period of intensely individualistic effort which is needful for pioneer development; but on the other hand it represents relaxation; it means transference of power from the atomic unit to the molecular unit. I am not saying which is better; I am pointing out a fact, and a great fact, fraught with mighty consequences. In proportion as we lose the influence of individual initiative we lose something that has made heroes, brave men, doers of wonders that will remain an inspiration to all times. There is the reverse side of this picture, to wit, the individual brute, trampling on the rights of other men. Are we sure that collectivism will not possess its collective brutality, its collective disregard of your rights and my rights, and those of your children and mine? But these changes are inevitable; the world will go as it listeth, as the wind blows, but the courts are our barrier-walls and wind-breaks to protect our homes, to give us the shelter of peace and security in the divine right to wrest out of the turmoil of life the only thing worth living for—happiness!

I said that the tendency away from individualism was growing in the West. I may illustrate it from events in the mining world, for I must perforce look at this world through the spectacles of an engineer. The West drew its initial strength from the mines, and the balance between the output of the mines and that of the farms is something that it is worth while to maintain for a long time to come if industrial conditions in the West are to remain universally healthy. There has been a tendency to grant that mining corporations may take precedence over the rights of individuals. For my part, I think that we have to admit that the welfare of the community is necessarily to be cared for by the courts, rather than to have our rights looked after by the individual. In a recent decision, which I believe is going to be reviewed soon in this State, it being rendered originally in Montana, the doctrine of the greatest good to the greatest number was set forth in the clearest possible terms. It was a decision by Judge Hunt, in the famous Anaconda smoke-case. There was the question of shutting down a smelter, which involved the cessation of mining operations, and the throwing out of employment of something like twelve thousand men, involving indirectly a population of about forty thousand people. There was no doubt in the world that the surrounding farms were being damaged. At first the injunction was granted, and then the injunction was set aside on the ground that a few could not take away food from so many mouths: and that was done in entire disregard of ample proof that damage was being done and that the continuance of farming was prejudiced throughout a large range around the smelter.

The question of the rights of individuals in Arizona was dealt with in a different way. A decision recently in the Arizona supreme court in connection with the Arizona Copper Company, recognized the right of the farmers; yet that decision has been set aside, pending appeal to the Supreme Court of the United States, so that an effort on the part of the judiciary to protect the individual in Arizona has so far failed.

I have been interested in noting in the court decisions this tendency to exalt the general proposition of the greatest good to the greatest number. My feeling has been that while that must necessarily go on, while we will continue to tenderly regard the mass, at the same time, we must be very careful that we do not lose sight of the units which make the mass.

Housing Conditions at the Garfield Smelter.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN

In settling upon a site for a smelting works regard is had, not only for convenience to railroad lines and to water-supply, but also to convenient places where the men may live. In the Salt Lake valley, Utah, however, the injury to the adjoining country from the emission of sulphurous acid fumes from the works, has compelled the selection of sites for new plants, distant from settled places, where the smoke can do but little damage, and where the smelting company can so control adjacent land that it shall not fear troubles from litigation. At the Washoe plant, Anaconda, Montana, the works are situated two miles from the town, and the company has provided a street-car system for transporting its 2000 employees to and from the works to their dwellings. At the new plant of the International Smelting & Refining Co., in Pine canyon, Utah, four miles from Tooele, trains take the men to their work, and Tooele itself, an old settled place, affords an attractive town in which to live. The works of the American Securities Co., at Garfield are 17 miles from Salt Lake City, the distance being made in 40 minutes. Taking the waiting-time at both ends and for the time spent on the street-cars in Salt Lake City, as much as three hours per day may be consumed by employees in going to and from their work. Part of this difficulty has been overcome by the establishment of a town at Garfield, about one and one half miles from the smelter. It has been planned to operate a street-car line for the employees, but this has not yet materialized. Consequently the advantages of Garfield are nearly nullified.

Smelting Works at Garfield, Utah.

When the works were started much foreign labor was employed, and many of the men built shacks below the works where they lived under temporary, primitive, and unsanitary conditions. They were not well under control, there was an unruly element among them, and disputes occurred, due in part to the free use of beer and liquor. It was found by the superintendent, H. W. Howard, that it was hard to retain proper labor, and he felt that suitable provision should be made to take care of these Greeks, Japanese, and Austrians. At Garfield, however, money had been spent on well built houses, all expenses of a townsite had been incurred, and no sufficient returns had appeared to be coming in on the money thus expended. Of course the reply to this would be, that having met all initial expense of water-supply, grading, stores, and public or semi-public buildings, all houses thereafter built would be constructed at a profit, though, on the other hand, it would be a question whether the new buildings would be fully occupied unless the street-car line were put in.

Naturally, with such an experience, the smelter management was slow to accede to the requests for the investment of more money to take care of men at the smelting works. The conditions, however, were adverse, and it was difficult to keep even the foreign laboring population, so Mr. Howard was finally instructed to put in comparatively simple accommodations. The new townsite or settlement now consists of 100 houses or cabins, each capable of accomodating six men, occupied by Greeks and Austrians; one large mess-house and dormitory used by the Japanese; quarters for the repair gang of the works; a store or supply-house, and a butcher shop.

The 100 cabins, 14 by 28 ft. in size, are one-story frame structures divided by a central partition into two rooms. They are unplastered, with the woodwork showing inside, the walls being one board in

thickness. They cost $130 each; one room being used for sleeping, the other for a kitchen and living room for the six men, who are charged $1 each per month—certainly a liberal return on the investment. After the first 75 houses were built the revenue from rentals was employed for the construction of new cabins.

The Japanese quarters consist of a house 120 ft. long, also of lumber, and costing about $2000. It consists of a central part of approximately 33 by 50 ft., used as a dining room and kitchen. The wings on either side are for the sleeping quarters of the men. In these the company has provided two high single iron cots with spring mattresses. At the end of each dormitory is provided a wash sink, and two cement shower-baths. The Japanese are a scrupulously clean people, and hence it is possible to accommodate them in these crowded quarters. This building is under the charge of a committee chosen by the men themselves, who keep up a strict discipline. Offenders are reprimanded or sent away by the committee chosen by the men, or by the manager to whom the committee is responsible. Meals are served in the dining room except in cases of accident or sickness, and at such hours as are convenient for changing shifts, each man returning his dishes to the kitchen. The food includes a good deal of rice, meat stew, tea, and some bread spread with jelly. Turns are taken by the men in cleaning their quarters, which operation includes a monthly disinfection. The clothes and other little properties belonging to the men are kept in lockers and trunks adjoining the cots. No gambling is allowed, and everyone is in bed by 11 p. m. The men generally go to bed by 7 or 8 o'clock, having a light supper, and rise early.

The high fence of the works adjoins the ground on the south. Openings are made through it to privies set inside, but separated from the plant, and these are used by all the men with some degree of privacy.

In the six-man houses occupied by the Greeks, the usual custom is to cook by some agreement among themselves, provisions being bought by the mess. They have cook-stoves with tile chimnies and depend on these for warmth.

Finally, and this has constituted the success and popularity of the whole settlement, food and supplies are furnished to the men at cost. The company has a store carrying food-stuffs and clothing, and the domestic supplies called for by the men. A storekeeper takes care of this at a salary of $125 per month, and he has the assistance of a clerk. A man cannot overrun his credit at the works, so that collections are assured. The average price for supplies is at least 20% less than elsewhere. Bread costs 4c. per pound. Meat is slaughtered near by and sold from a butcher shop on the ground. A good deal of beer is sold at the rate of $2.10 per case. Of this the Greeks consume about one bottle daily, and the Austrians three.

To maintain order, a mayor is employed, who also acts as sheriff. He enforces excellent discipline, and the settlement is peaceful. To keep the place clean a garbage cart goes around daily.

The Japanese are noted for their eagerness to learn, and the interest they take in their work. They are able to do considerable mechanical and repair work; though the work of the regular mechanics, bricklayers, carpenters, and machinists, is done by white labor. The Greeks take comparatively little interest in their work, but can be relied upon to carry it on steadily, without objection to furnaces and danger. The Austrians, who are a large and vigorous people, are depended on for the heavier work.

TOPOGRAPHIC SURVEYS IN NORTHERN IDAHO

During the field season of 1909 topographers of the United States Geological Survey mapped parts of the Panhandle of Idaho. Nearly the whole region surveyed, amounting to about 1000 square miles, lies within the Coeur d'Alene and Pend Oreille national forests, and it is expected that the maps will be of great assistance in the future development of the abundant timber, water power, and mineral resources of this part of the State. The party making the survey was in charge of William O. Tufts.

The region is generally rugged, with long ridges covered almost entirely with timber and brush. The highest mountain south of Clark Fork is Packsaddle, 6415 ft. above sea-level. Grizzly mountain, north of Nelson's siding, on the Idaho Northern railroad, is 5977 ft. in height, and a high ridge east of the junction of East Fork with North Fork of Coeur d'Alene river reaches an elevation of 6237 ft. The Cabinet mountains, north of Clark Fork, are much higher and more rugged. Scotchman is 7011 ft. high, and many other peaks in that range reach heights of nearly 7000 ft. Pend Oreille lake lies at an elevation of 2051 ft. The snowfall, from October 15 to June 1, is heavy, amounting in places to a depth of more than 30 ft. Snow remains throughout the year on the northern slopes of the Cabinet range, though not in large quantities. At lower levels, to the south, it disappears about June 15. From June 15 to October 15 there is little rainfall, and forest fires at this period of the year were formerly very destructive, but the fire guards stationed by the Forest Service at strategic points throughout the summer months have greatly reduced the damage.

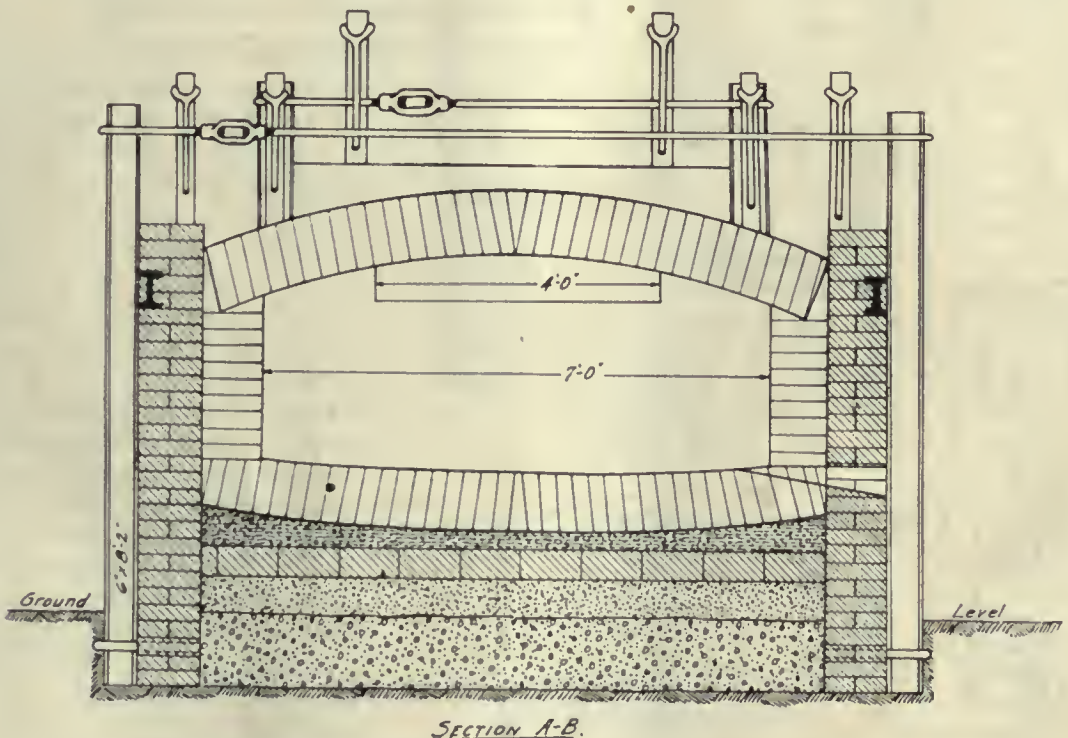
The population of this region is sparse. Only small areas are level and fertile enough for cultivation, and the climate is not favorable to agriculture. Severe frosts occur every month in the year in most parts of this country. The lower valleys of the Coeur d'Alene and Clark Fork, however, are cultivated profitably. The mineral resources of the region are practically unknown. Timber and brush made the work of mapping difficult. Through nearly the whole region, outside of the settled portions, narrow trails afforded the only routes of travel; so that camp outfits were moved by pack horses exclusively. Several varieties of bear and deer, large numbers of grouse, and almost unlimited quantities of trout are found in the more remote parts of the region. Elk, moose, and caribou are practically extinct. The Forest Service is building new trails and the wilderness is becoming more accessible to the prospector and sportsman each year.

Smelting Copper in Small Reverberatory Furnaces

Written for the Mining and Scientific Press
By Edwin M. Clark

About October 1902, the Richardson brothers employed me to go to their mining properties, situated in the rugged mountanous district of Sahuaripa, Sonora, Mexico, about 150 miles by trail in an easterly direction from Torres, a small station on the Sonora railroad, to investigate the possibility of smelting their ores. At that time they were shipping each month, by pack-mules and burros over the above trail, something like 45 tons of first-class ore and concentrate from their mine at La Bufa, and the same amount of concentrate, with from $6000 to $10,000 worth of silver sulphide from the lixiviation plant at Santa Rosa.

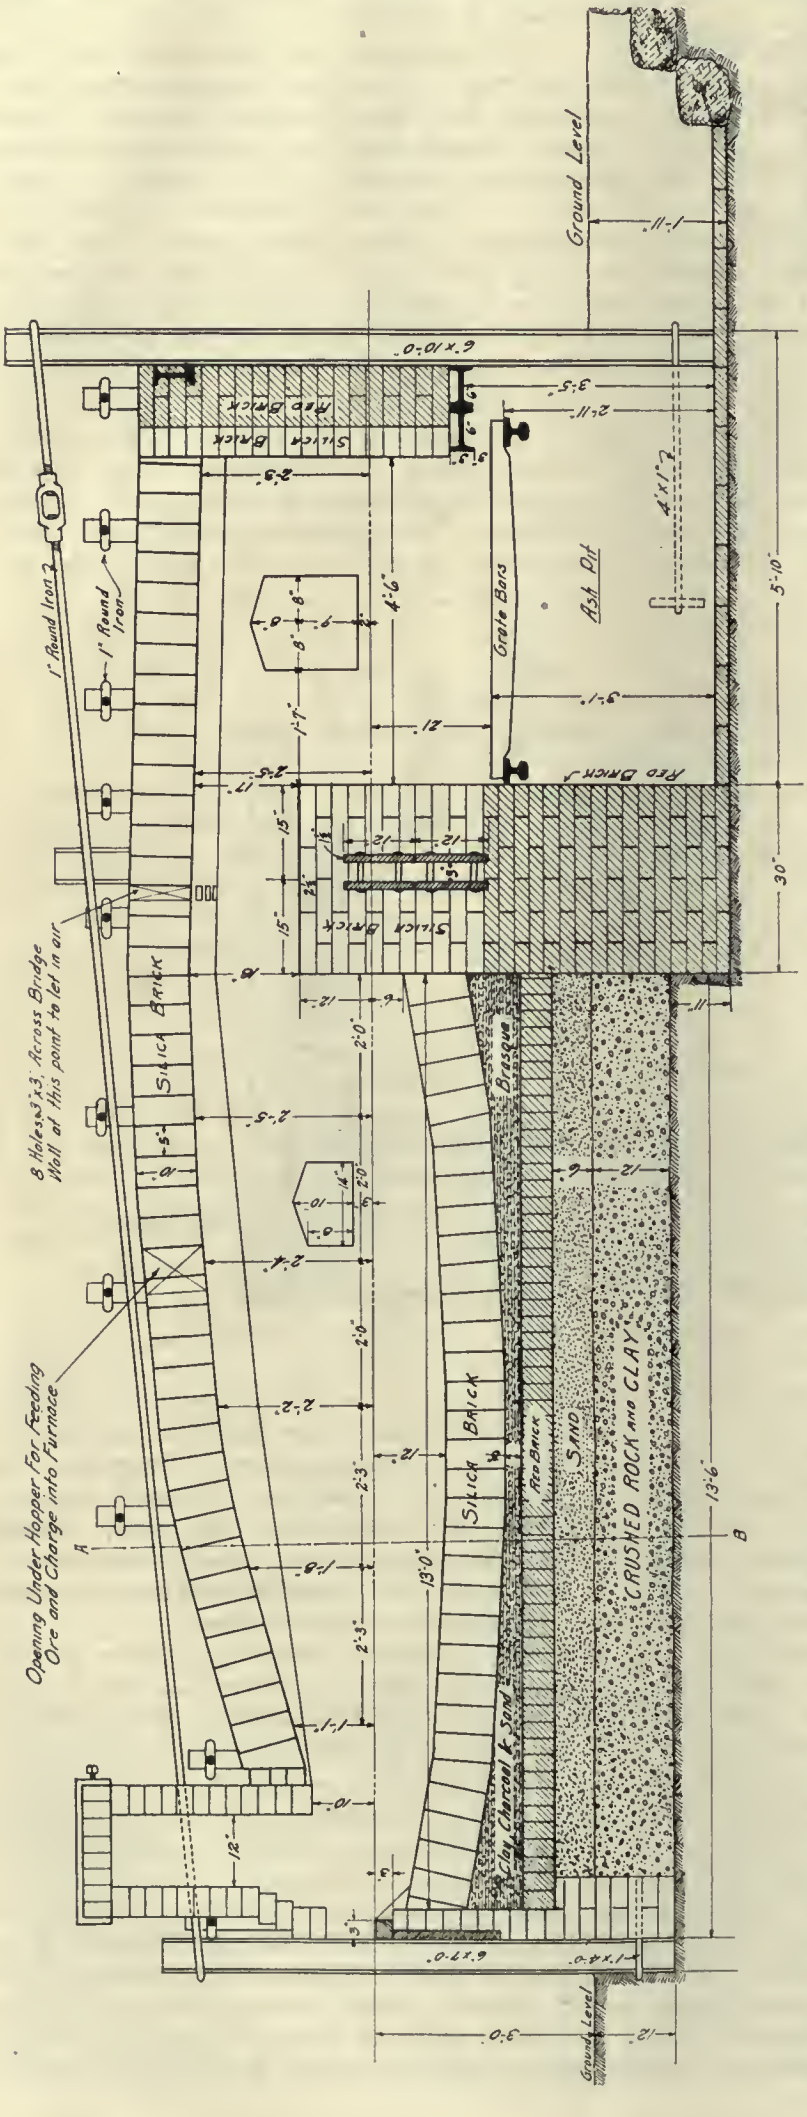
The method of procedure was as follows: The ore as it came from the mine was first hand-sorted to separate the first and second-class ore from the fine which latter was passed over shaking screens so as to classify it. The coarse product was hand-jigged at the mine and the concentrate obtained was added to the first-class ore. The middling from these jigs and all the other fine and the second-class ore, amounting to about 200 tons per month, was sent by mule back, nine miles to Santa Rosa, at a cost of $8 per ton; where the coarser ore was crushed with rolls and concentrated on jigs and tables, the middling and fine going to stamps to be crushed fine enough to chloridize by roasting with salt in small hand-roasting furnaces. The soluble copper salts were then washed out with water and run to waste. The chloride of silver was leached by hyposulphite of soda and lime, precipated with sulphide of lime, dried, sacked, and shipped to the railroad. This was an expensive operation. The manager saw that if he could smelt the ores at the mine it would reduce this local expense as well as save the copper they were losing; besides by concentrating the copper-silver into matte or black copper, it would make an enormous saving in the transportation expense to the railroad. I recommended reverberatory smelting, on account of its adaptibility to making copper matte using cord-wood for fuel. It also required less metallurgical skill than a blast-furnace. The ores being coarse and fine concentrate would not have to be briquetted after roasting, so the zincy lead-copper concentrate, rich in silver, would be reduced with less loss in fume and flue-dust than in a blast-furnace. I was requested to take charge of the metallurgical department and proceeded to make plans for the mill and furnaces. These consisted primarily of a 24-ton concentrator and a 14 by 50-ft. roasting furnace,



Section A-B.

built of stone and red brick at a cost of about $3000, which was connected to the same flue as the smelting furnaces. The flue consisted of a trench run up the side of a hill to the top of a small butte on which was built a 20-ft. stack. The trench was 300 ft. long. When arched over it had a dimension of 4 by 6 ft. in the clear, and a height above the reverberatory furnace of about 110 feet.

The roasting furnace would desulphurize 12 tons in 24 hours, of a mixture of first-class ore and concentrate, from 23.8 down to 7%; three Mexican cords of wood (96 cu. ft.) were used per day, seven men were employed on a shift of 12 hours, including the foreman, and the *cargador* who brought up the charge and wood. A small 7 by 13-ft. reverberatory furnace, the description of which is the subject of this paper, was also built. Through the courtesy of the La Dura Milling & Mining Co. I obtained their hand brick-press, of German make, which molded a brick 2½ by 5 by 10 in., with which were made all of the common and silica bricks needed at the rate of from 1200 to 1500 per



day. In searching for material to make the refractory bricks, I found an inferior fire-clay at Ocotes, some 15 miles north of the mine, which gave the following analysis:

	Per Cent.
SiO_2	68.77
Fe_2O_3	3.96
Al_2O_3	16.64
CaO	2.23
Loss by ignition	4.12
	95.72

Also a quartzite was found at La Trinidad 17 miles away, which was crushed dry at the mill, fine enough to pass a 30-mesh screen. This gave the following analysis:

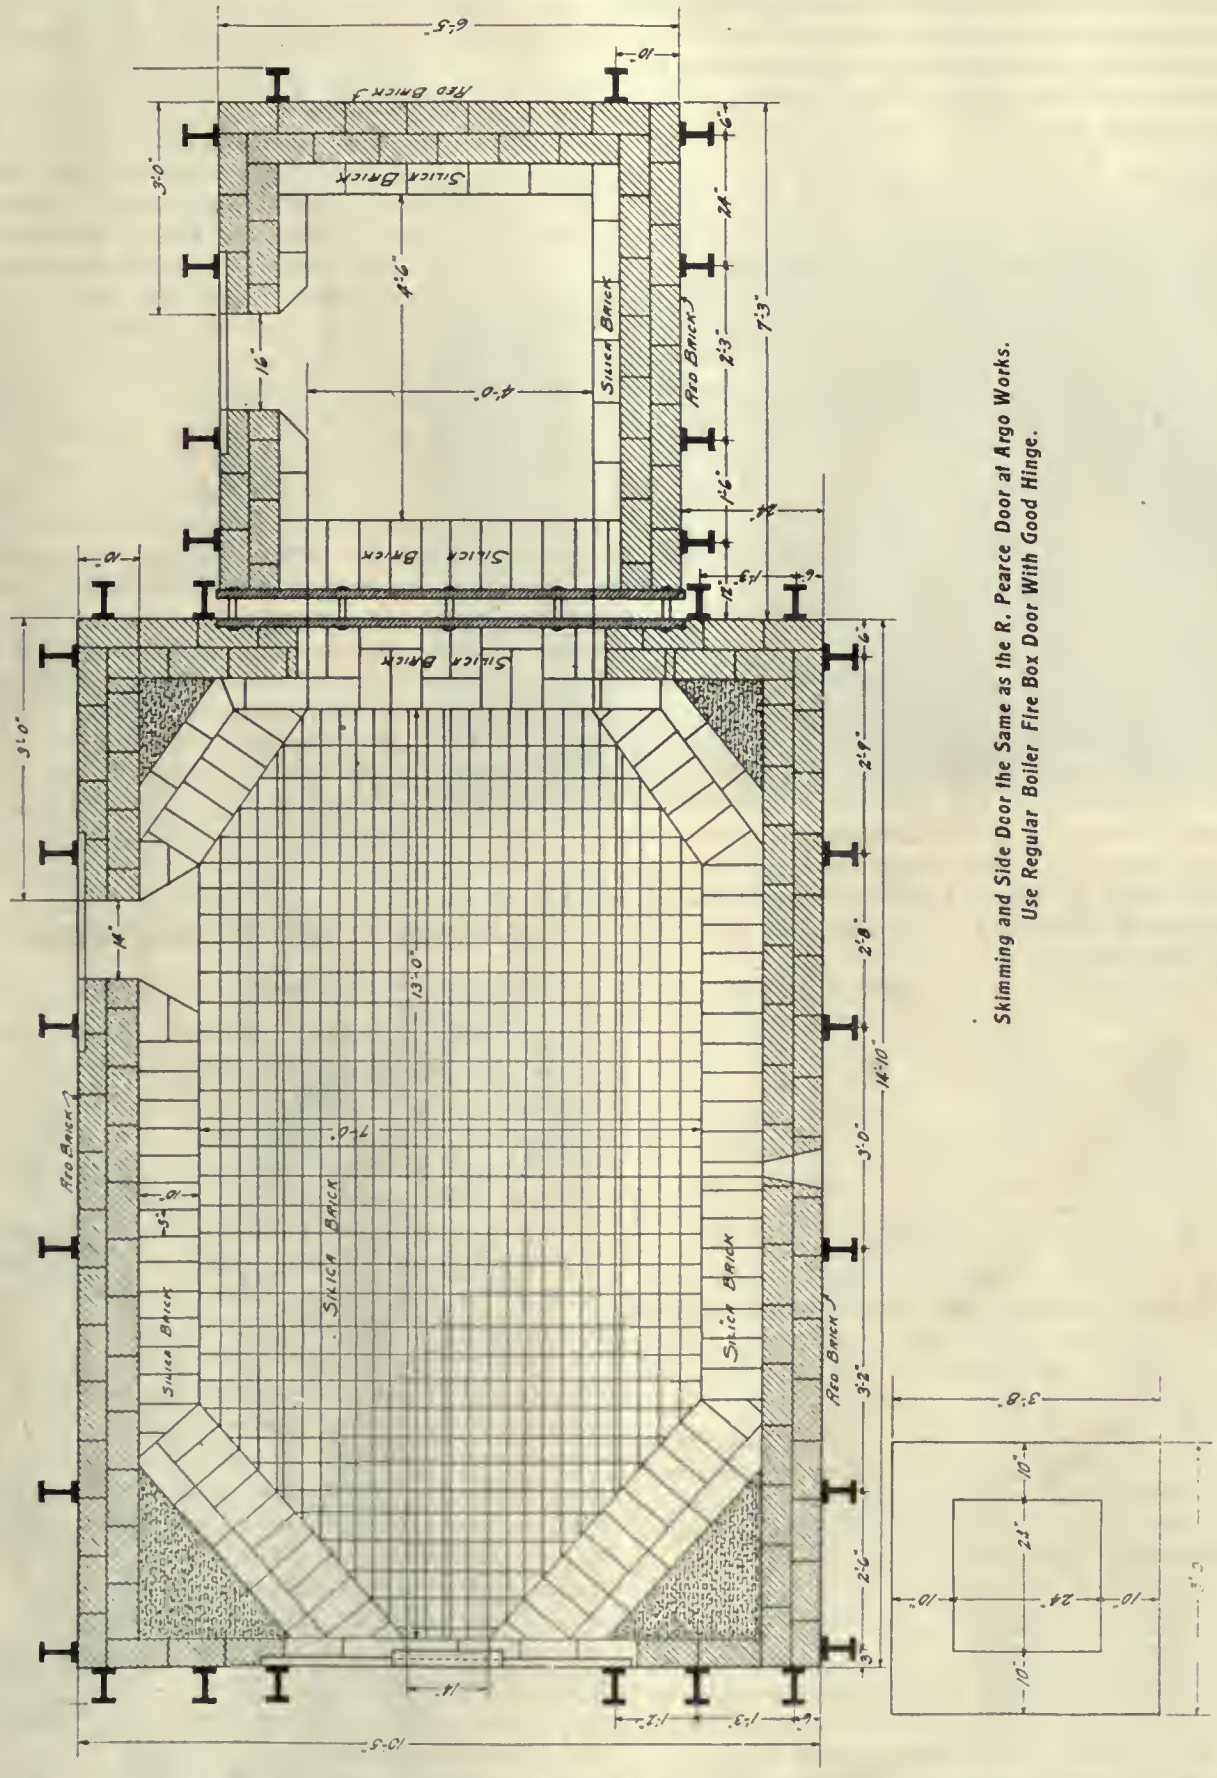
	Per Cent.
SiO_2	95.15
$Al_2O_3+Fe_2O_3$	4.15
CaO	0.60
	99.90

To make the silica bricks, 2 parts of the crushed clay were mixed dry with 5 parts of pulverized quartz (by measurement) in a mortar box, and enough water was added to make a batter of the material, of the same consistence as ordinary lime-mortar. After thoroughly mixing, it was thrown upon a canvas to dry until stiff enough to press into bricks. In the meantime other batches were made in a similar manner, so that the pressing of the bricks could continue uninterruptedly. The reason for this was to get an intimate mixture of clay and quartz. the bricks when molded were carried by boys upon a small piece of board to a level patio, where they were placed to dry, after which they were built into the centre of the kiln. The outside and arches of the kiln were built of common brick so as to protect the more fragile silica-bricks. The common red brick was made from clay and sand found near the mine. The silica-brick when burnt gave the following analysis:

	Per Cent.
SiO_2	90.10
Fe_2O_3	2.67
Al_2O_3	5.33
CaO	1.25
	99.35

These bricks were rather fragile but stood the fire well.

As will be seen by the plan of this 7 by 13-ft. hearth-furnace, it was built without a vault, starting upon a solid foundation of country rock. The outline of the furnace was built of red brick, and when high enough the tie-rods were put in place and the walls continued. A foot of crushed rock and common clay was tamped in the bottom, after being slightly moistened: upon this was placed 6 in. of



Red Brick

pleted the floor must have the shape and conform to that given to the brasque beneath. The ends of the bricks where they join the outer wall of the furnace, are cut sufficiently to allow the 10-in. lining or inner wall of silica-brick to have a firm seat upon them; then the walls are completed to where the skew-backs are placed for the arch. To build the arch, I filled the body of the furnace with sand to within a few inches of the skew-backs, upon which was tamped a mixture of clay and sand a little fuller than was necessary for the forming of the arch; this was scraped to the desired form, and the brick laid upon it by beginning at the chimney end, placing the buckstaves and tie-rods as they were reached and driving the wedges just tight enough to raise the row of bricks a little above the form beneath. There were provided one hole for the feeding of the charge and eight small holes over the bridge-wall to admit air for perfect combustion. When finished the sand is withdrawn, and the hearth swept out, the doors put in place, and about ½ ton of pulverized slag placed upon the hearth around the edges. It is then gradually dried, the doors are closed and brought to the highest heat possible. Leaving the doors sealed the fire is allowed to go down until the hearth is dull red, when the first charge of one ton of sulphide ore is added and quickly smelted in. Then follow the regular charges of 1½ tons. It required about 7 days to fill the hearth with matte and it yielded about 9 tons of matte when tapped.

The calcine smelted had the following analysis:

	Per Cent.	
SiO_2	31.62	
FeO	15.34	
Al_2O_3	12.52	
CaO	tr.	
PbO	9.00	
ZnO	7.40	
S	6.10	
Cu	13.10	
Ag	0.634	(0.634%=185 oz. per ton)
	95.614	

The matte produced had the following composition:

	Per Cent.	
Cu	50.5	
Pb	12.0	
Zn	3.2	
Fe	4.2	
S	25.0	
Insol. residue	2.1	
Ag	2.225	(2.225%=661 oz. per ton)

The slag gave analysis:

	Per Cent.	
SiO_2	44.10	
FeO	20.60	
Al_2O_3	16.64	
CaO	5.28	
PbO	3.40	
ZnO	9.10	
Cu	0.70	
Ag	0.026	(0.026%=7.6 oz. per ton)

The slag shows the silver to be too high for good work, but this was due to the fact that I did a great deal of smelting with green wood, and it was almost impossible to drive the charge as rapidly as it should have been done at a time when the gases were coming off freely. With dry *mauta* or pine wood, I was able to smelt at the rate of ¾ cord of wood per ton of charge, and to skim each charge of 1½ tons every 2 hr. and 30 min. The best we attained was 2 hr., 7 min. With this small furnace I smelted over 1000 tons in four months, and the furnace was in as good condition as at starting. It could have been run for a long period with reasonable repairs. It was abandoned for a larger furnace, with a 10 by 20-ft. hearth, built in the same way, which was used intermittently for three years. I say intermittently, because it was closed 7 times one season, and 9 times another, on account of trouble in getting freighters to pack in the wood, due to rains and to the Indian war in progress at that time in the Yaqui district. I employed one American on each shift as skimmer, and two Mexicans to fire the furnace, remove the slag and ashes, and another Mexican to bring up the wood and to help put the charge into the hopper.

In regions remote from transportation, where wood is abundant and inexpensive to obtain, if the management will use nothing but well seasoned dry wood, and have sufficient ore available for a long campaign, the small reverberatory smelting furnace above described, can be made to smelt between 10 and 15 tons per day of 24 hr., with less than ¾ cord of wood per ton where one-half of the charge is hot calcine. Any intelligent person who will be careful of the material used can make a silica-brick which will stand well in such a furnace. I do not, of course, recommend wood where coal can be obtained.

PLATINUM IN THE UNITED STATES

By David T. Day

*While recent high prices have caused active search for platinum, which has brought out the fact that it is widely distributed in many rocks, useful accumulations in the United States are at present limited to the Rambler mine, in southern Wyoming, the Key West group of mines in Bunkerville, in eastern Nevada, and to about seven important groups of accumulations in connection with placer mines of the Pacific slope. Most platinum was produced last year from the neighborhood of Oroville, California, where it occurs about in the proportion of 1 to 500 of gold. The proportion has not been determined for Trinity county, California, and Josephine county, Oregon, the other two inland localities. On the coast, platinum is found in the proportion of 2 to 1 of gold, near Surf, Santa Barbara county, California, but other places in the same region, including San Luis Obispo, show only 1 to 20 or 1 to 50 of gold. The next important group of accumulations is found near Trinidad Head, Humboldt county, California, another at Crescent City, California, at the mouth of Smith river, Oregon, and one on the South Fork of Smith river. The most important group of all extends from the mouth of Rogue river north to Coquille river. At Cape Blanco an accumulation of platinum has been found where that metal is five times as abundant as gold. On the west coast of Washington platinum is comparatively abundant in the proportion of 1 to 10 and 1 to 15 of gold.

*Read before the Washington Geological Society and abstracted from *Science*.

Pasto Gold District, Colombia

The accompanying illustration shows a charming city in southern Colombia, which is perhaps one of the least known towns in South America. It is a clean and rather progressive city of more than 20,000 inhabitants, situated in the Andes near the active volcano also called Pasto, and it is now the administrative head of the Department or State of Nariño. Although only one and a half degrees north of the equator its altitude of 8311 ft. above the sea gives it a pleasant and healthful climate, the average mean temperature being 58°F. It is on the great highway or *camino real* which was opened in Colonial times all the way from Cuzco, Peru, to Cartagena on the Caribbean Sea as a safer route for the shipment of treasure than by galleon to Panama, exposed as Spanish shipping then was to the buccaneers. This route is still open and is regularly traveled. The ride up the Cauca valley from Cali by way of Popayán to Pasto is not

Pasto, Colombia.

Map of Colombia.

fraught with any difficulties, being through a fairly open country most of the way, but it is long and tedious. The city is more commonly reached by taking the coasting steamers from Panama, stopping at the port of Tumaco, 310 miles distant. Small steamers ascend the river Patia from Tumaco, coming within 125 miles of Pasto. A wagon-road is now being built from the city to this fluvial port. Pasto is only 186 miles from Sofia, the head of navigation on the Putumayo river, which flows into the Amazon, to which point a wagon-road is also being constructed.

The commercial importance of Pasto is quite largely due to the widely distributed gold placers in that part of Colombia. Over the doorway of nearly every store in the city runs the announcement 'Compro Oro en Polvo', gold-dust being the universal article of trade with the surrounding country. Veins have also been prospected, and the indications are that mining and milling in the modern way will soon become established on a good scale at many points in the Department. Despite the riches of the Cauca, the Atrato, and the San Juan, the outlook for the development of a great and permanent gold-mining industry in the vicinity of Pasto is perhaps even brighter. For one thing, the veins are more numerous, and the handicap of a climate unfavorable for northern peoples does not exist. The territory on the eastern side of the Andes, in the valley of the Putumayo has been less prospected, but the occurrence of widely extended placers of fair grade is known. It is a region well meriting the attention of prospectors. The photograph from which the accompanying cut was made was kindly furnished by F. Pereira Gamba of Pasto.

Commercially valuable feldspar is now mainly obtained from rocks known as pegmatites, the commonest variety of which is essentially a very coarse granite. Feldspar is mined and ground for use by potters, but a portion of the product is used in the manufacture of emery and other abrasive wheels, to bind the abrading particles together, and small quantities are employed in making opalescent glass, scouring soaps, roofing material, and poultry grit.

Sensitive Test for Explosives

By H. Kast

* The Royal Military Experimental Bureau of Berlin has been occupied for the last 20 years in the examination of explosives for military purposes. Professor Lenz, at the last congress in Rome, reported exhaustively on the accumulated results of these investigations. It need only be remarked that experience has shown that the drophammer must not be allowed to act directly on the explosive, chiefly for the reason that the sensitiveness, as ascertained by means of the drophammer, depends in the greatest degree on the area of the struck-surface, and it is not possible to keep the struck-surface unchanged under the direct action of the drophammer. If the drophammer be allowed to act directly, or indirectly through an interposed piston, on an uneven layer of the explosive spread directly on the anvil, the area of the struck-surface will change in proportion to the varying thickness of the layer in different spots; but then it is impossible to obtain strictly proportional values, because the percussive energy is distributed over surfaces of different area. This drawback can be avoided by interposing a contrivance between the drophammer and the anvil, which is so arranged that only a strictly defined surface is exposed to the blow. This contrivance must comply with the following conditions:

(1.) The surface to be struck must be a definite and invariable area. (2.) The explosive must be so arranged that it cannot spread out sideways. (3.) Any frictional action of the blow must be avoided as carefully as possible, as explosives behave quite differently under friction to what they do under percussion.

Thus the chlorate explosives are more sensitive than dynamite to friction, but less sensitive to percussion. Further the explosives must not be rubbed between hard materials. For this reason it is not permissible to add frictional materials (powdered glass, sand) for the artificial augmentation of the sensitiveness to shock in the comparison of dissimilar explosives, since that would affect the natural ratios of explosives sensitive to friction too seriously. Special methods are used for testing the sensitiveness to friction. As a fourth condition there must be a constant increase of sensitiveness with the height of the fall. (5.) The limits of sensitiveness must be the same whether the tests are made starting with a low fall up to a higher, or the reverse. (6.) The values found at different times must agree with one another within certain narrow limits; and in particular the ratio of the sensitiveness toward that of the explosives with which it is compared must be constant. (7.) The force of the blow developed with different weights for the given limit-values must be about the same; but it must also be recognized that by the use of different weights the ratio of sensitiveness is somewhat changed, on account of the different physical properties of the explosive, the varying velocities of impact, and the different dissipation of the kinetic energy because of the greater rebound of the lighter weights.

Explosives which can easily evade the blow (namely fluids like nitro-glycerin) show themselves more sensitive to a light, swift-acting weight than to a heavier weight. (8.) Sharp differences should be observed with low falls, since experience shows that these differences are less marked as the height of the fall increase. (9.) Proportionally insensitive explosives should also be tested comparatively. (10.) It must be determined, beyond any doubt, whether the explosion is entire or only partial, or whether the explosive has merely burned; from these results conclusions can be drawn as to the danger of unexpected detonation induced by shock.

Care must be taken that the layer of the explosive exposed to the blow is not too thin, as this renders explosion more difficult. In the ordinary way of testing, the air-waves from the drop-weight, and those produced by partial explosion, blow away the explosive, especially when pulverulent, so that the sample appears to have been completely exploded.

These conditions are best fulfilled by an instrument having striking surfaces exactly 0.5 sq.cm. (= 0.0775 sq. in.), with a drop not exceeding 60 cm. (2 ft.) for the more insensitive explosives. The stamp or piston must fit the ring closely, and yet admit of the free motion of the piston. Both striking surfaces should be ground smooth, exactly 8 mm. (0.315 in.) diam. The appartus should be fixed in a cylindrical bed on the anvil to avoid damage from the drop-weight. After measuring the explosive it is pressed by twisting both stamps so that an even layer is spread over the whole surface. The best temperature for the test is from 18 to 20°C.

* Abstract from *Journal* of the Franklin Institute.

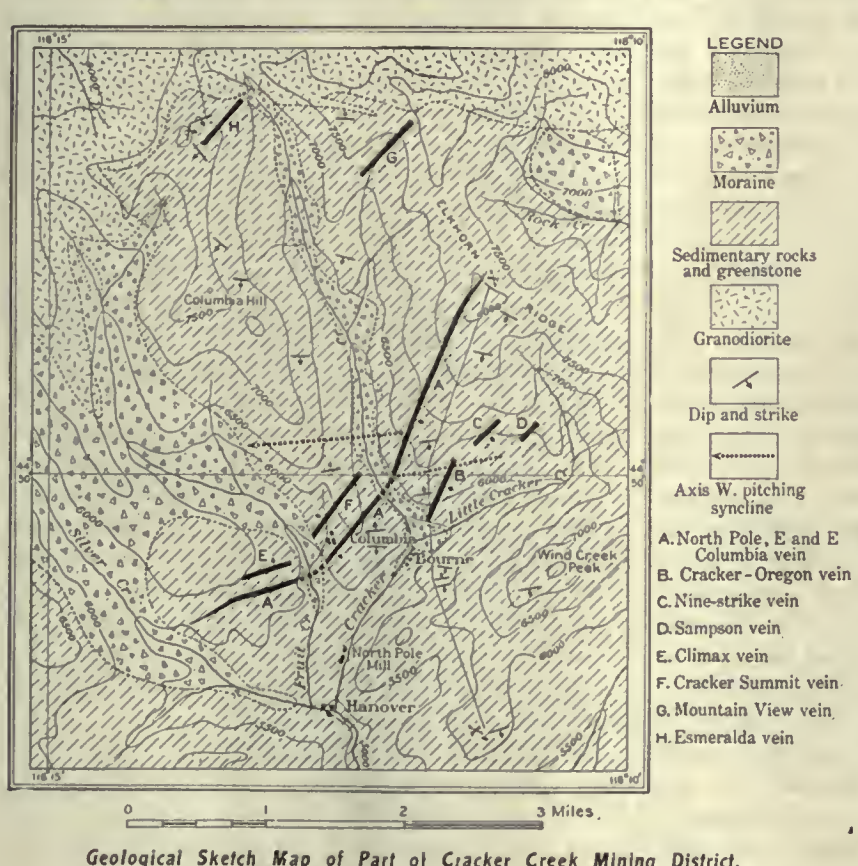
California oil-land withdrawals made prior to March, 1909, aggregating 2,313,482 acres only, prevented the acquisition of the withdrawn lands under the agricultural land laws. All lands covered by these withdrawals could be legally exploited for oil or other minerals. During the year ended March 4 these lands were excepted from acquisition as oil or as mineral lands as well as for agricultural use. New withdrawals were made in the States of California, Colorado, Oregon, Utah, and Wyoming of a total area of 2,130,510 acres. In California there were restored to entry 956,916 acres that field examination had shown to be non-oil land. The area now covered by oil withdrawals is 3,487,076 acres.

Paris stands 226 miles above the mouth of the Seine, measured along its course, and the area drained by the river above the city is only about 17,600 sq. mi. The mean discharge of the Seine at Paris is about 9000 cu. ft. per second; its greatest discharge in the flood of 1876 was 58,600 second-feet; its discharge at the height of the recent flood (January 27, 1910), is reported to have been 83.500 second-feet. This is less than one-eighth the flood flow of the Susquehanna in 1889 (720,000 second-feet) and less than one-fifth the flood flow of the Potomac at Washington in the same year (470,000 second-feet), when boats were paddled along Pennsylvania avenue, in the heart of the city.

Cracker Creek District

By J. T. Pardee

* The Cracker Creek mining district is situated in the northwestern portion of Baker county, Oregon. It is a small integral part of the Blue Mountain gold belt, which has been described by Lindgren[1], and as generally understood comprises the drainage basins of Cracker and Fruit creeks. The town of Bourne, six miles north of Sumpter, is the principal settlement within the district. The principal mines are the North Pole, Eureka & Excelsior, Columbia, and Golconda, all situated, from northeast to southwest in the order named, on one persistent fissure, the North Pole-Columbia vein, or 'mother lode,' as it is locally designated. At present the Columbia is the only producing mine in the district, but the suspension of operations in most of the others is believed to be temporary and not caused by exhaustion of the orebodies. In addition to those above mentioned, there are a number of smaller mines and prospects on which annual assessment and considerable development work is being done. Time in which to visit all the mines was not available, but in November 1908, during the progress of field work in the Sumpter quadrangle, in the northern part of which this district lies, advantage was briefly taken of opportunity to visit the underground workings of the Columbia and North Pole mines. The aggregate production of the mines on the mother lode is estimated to be at least $7,000,000.



Geological Sketch Map of Part of Cracker Creek Mining District.

The rocks most extensively developed about the Cracker Creek mines are argillaceous and silicious sediments, non-fossiliferous so far as known, and very fine grained throughout. The composition of the beds varies from that of chert consisting almost wholly of silica to that of highly aluminous blue-black slate. These types, however, are rarely found in complete purity; they grade one into the other, and are at many places interlaminated, the cherts in particular being divided into thin sheets and lenses by argillaceous partings. Seen in distant views, the weathered outcrops of the sediments everywhere appear rather dark in hue and more or less rusty with oxide of iron. The impression conveyed by a cursory examination is one of monotony and of a lack of sharp lithologic distinctions. Only long continued and careful observation made it possible to recognize lithologic subdivisions of the stratigraphic column. The series appears to be conformable.

The rocks of igneous origin are intrusive granodiorite, surrounding the sedimentary area on the north and northwest; some dikes, observed to cut both the argillite and the granodiorite, varying in thickness from a few inches to 20 ft. or more, that appear to be mainly altered feldspar porphyries; a few aplitic dikes; some small masses of serpentine; and a greenstone, probably an interbedded lava or intrusive sill. This last-named rock is most conveniently considered in connection with the sedimentary rocks, which are probably of Paleozoic age.

The most readily noticeable structural feature of the more silicious of these beds consists of the contortions and small close folds they everywhere exhibit. The black argillites have a slatey cleavage that as a rule coincides with the bedding. Some of them are closely folded also, but as their bedding is less distinct than that of the silicious rocks their structure is more obscure. Faulting of an extreme distributive type is developed throughout the district. This faulting is so common that portions of the district, as for instance the northern half of Columbia hill and Elkhorn ridge, from the summit of North Pole hill northward to the intrusive contact, may be said to resemble huge fault breccias. The dimensions of the faults descend to the microscopic, and nearly every joint and cleavage plane shows polishing or striae as evidence of movement. All faults in the district whose attitude has been determined are normal, and steep dips are the rule.

The Cracker Oregon vein is 4 to 8 ft. wide and dips steeply to the southeast. The Cracker Summit vein is 4 to perhaps 12 ft. wide and dips 50 to 70° northwest. Both are said to have produced pay-ore; their vein-filling resembles that of the mother lode

* Abstract from 'Contributions to Economic Geology, 1908,' U. S. Geol. Sur., Bull. 380.

[1] Lindgren, Waldemar, 'The Gold Belt of the Blue Mountains of Oregon': Twenty-second Ann. Rept. U. S. Geol. Surv., pt. 2, 1901, pp. 551-776.

and their walls bear evidence of movement. The Cracker Summit vein has at several points been displaced by faults of the other groups, but the exact details of the faulting have not yet been worked out. The 'mother lode' stands out as a most prominent economic and structural feature. It is a normal fault extending beyond the limits of the district. The portion of it here particularly referred to is that extending from the Columbia shaft to the limit of the North Pole stopes, a distance of 7500 ft. On this portion of the vein are situated the Columbia, Eureka & Excelsior, and North Pole mines, from southwest to northeast in the order named. The displacement along this fracture, which in the North Pole dips 70° southeast and strikes N.34°E., was approximately determined where it crosses Columbia hill to be a vertical displacement of at least 400 ft. But in addition to the vertical throw the fault causes a horizontal displacement of approximately 1800 ft. The vein may be said to divide the district into two fault-blocks. With respect to the northwestern or Columbia Hill block, the southeastern or Bourne block has settled and moved southwest by south, or along a line lying in the plane of the vein and pitching gently to the southwest. The large amount of development work that has been done on the 'mother lode' offers excellent opportunity for investigation of the structure due to complex movements within the vein. The Columbia mine is opened by three adit levels and a 900-ft. vertical shaft with which cross-cuts and drifts connect at each 100 ft. The aggregate of development is stated by F. S. Baillie to be, in drifts and cross-cuts, 19,470 ft.; in shaft, raises, and stopes, 29,274 ft.; total, 48,744 ft. The shaft is sunk in the hanging wall 45 ft. from the vein, which it penetrates at a depth of 800 ft. Northeast of the shaft the vein is well defined and 20 to 100 ft. wide. The ore-shoots, 3 to 8 ft. in width, are found on the foot-wall in all but the upper (adit) levels, where they have crossed to the hanging wall. The pay-ore is usually separated from more barren quartz by walls lined with thinly laminated black gouge. The ore-body itself is separated into overlapping wedges or thick lens-like masses by seams of black, laminated, striated gouge. About 200 ft. south of the shaft the vein loses its identity in a zone characterized by a great number of faults. The gouge linings of these faults nowhere fail to exhibit evidences of movement as above described. Within this zone isolated masses of ore are found.

The North Pole mine is not at present in operation. It is developed by five adit levels and one intermediate level, aggregating 12,500 ft. and a large extent of cross-cuts and stopes. At 1800 ft. from the mouth of tunnel No. 1 a fault displaces the ore-shoot 45 ft. to the southeast. On following this fault for about 500 ft. to the intermediate level, the displacement is noted to be small, and the slip appears to coincide with a flat wall forming the lower boundary of the ore-shoot for a distance of about 1200 ft. farther on. This orebody widens above, attaining a maximum of 25 ft. just under tunnel No. 3. In the main stope the ore lies on either wall or occupies intermediate positions. In some places the ore is observed to cross from one position to another on transverse, southwestward-dipping, obliquely striated fault planes which do not pass without the vein.

The results of structural study in the Cracker Creek district indicate that the 'mother lode' is not notably displaced by transverse faults. Within the vein itself, however, there are faults which affect the orebodies. Some of the smaller veins have been offset by faulting. The fact that the faults of known attitude are normal, and that in the movement upon them the horizontal component is commonly as important as the vertical one, should be taken into account in the development of such of the orebodies as have been displaced.

The zinc ores of Tres Hermanas, New Mexico, according to Waldemar Lindgren, occur as dark-gray cellular masses and consist largely of the unusual mineral willemiate, the pure anhydrous silicate of zinc. Smithsonite, the zinc carbonate, is also present in its usual mammillary form and light-gray or bluish color. Hydrozincite was shown to be present by W. F. Hillebrand as an earthy incrustation. Tabular crystals of calamine, the hydrous silicate of zinc, were noted in crevices of the ore. Willemite appears to make up the bulk of the specimens collected. It is accompanied by a little black pyrolusite, which gives a dark tinge to the ore, and it forms small radial aggregates of slender hexagonal prisms, terminated by flat rhombohedra. It also forms loose crystalline aggregates and crusts of needle-like crystals. This habit is unusual, the more common form being a short, stout, hexagonal prism. The occurrence of these ores seems to be paralleled only by that at Moresnet, in Belgium, where the willemite is also accompanied by galena. The only other occurrences noted in this country are at Franklin Furnace, New Jersey, and as rarities at Clifton, Arizona, and at the Merritt mine, in Socorro county, New Mexico. The zinc minerals of Tres Hermanas are beyond doubt derived from zinc blende by oxidation.

The principal zinc minerals of Tres Hermanas and their tenor are as follows: Willemite (Zn_2SiO_4). zinc silicate, 58.6% Zn; calamine ($H_2Zn_2SiO_5$), hydrous zinc silicate, 54.7% Zn; smithsonite ($ZnCO_3$). zinc carbonate, 52.1% Zn; hydrozincite ($ZnCO_32Zn(OH)_2$), basic zinc carbonate, 59.9% Zn.

The zinc ores shipped from Tres Hermanas probably contained about 30% of zinc. The shipments of lead-zinc ores made from one mine are stated to have contained from 11 to 40% of lead and 2 oz. of silver per ton. They also contained up to 19% of zinc, 4 of lime, 4.2 of iron, and 7.40 of silica.

The Seine at Paris runs between stone walls in a channel that is spanned by many bridges. The width of this channel may be seen by noting that the largest and finest of these bridges—the Pont Alexandre Trois—is but 352 ft. long. During the recent flood constriction of flood water within this relatively narrow channel was impossible, so it overflowed a large area along the banks of the Seine.

Feldspars that are rich in potash are now the subject of experiments made to determine their value as fertilizers.

PROPOSED SEISMOLOGICAL INSTITUTE

The following resolutions were passed at the San Francisco meeting of the Seismological Society of America, March 2:

Whereas earthquakes which are normally recurring phenomena of the earth's crust, have in the past caused considerable loss of property and life, and much of the distress and destruction has been due to lack of knowledge of earthquakes and their peculiar mode of action and of proper precautions against injury and, *whereas* the magnitude of the destruction in the Atlantic Coastal region (Charleston earthquake of 1886), the Mississippi Valley region (earthquake of 1812) and the Pacific Coastal region (California earthquakes of 1857, 1868, 1872, and 1906), makes it a matter of great import to all the people, and the fact that with increasing density of population the conditions are becoming more favorable for greater destruction in the future makes it important that action be not longer delayed, *whereas* the problems involved are of national and international character and local authority or private enterprise is insufficient to successfully carry on such work, and this fact has been realized already by many of the great nations including the German, English, Japanese, Austro-Hungarian, Italian, and Spanish which have already established scientific earthquake services for the benefit of their peoples and the world at large.

Resolved that the Seismological Society of America strongly favors the establishment of a National Bureau of Seismology with power (a) to collect seismological data; (b) to establish observing stations; (c) to study and investigate special earthquake regions within the national domain; (d) to co-operate with other scientific bodies and organizations and individual scientists in forwarding the development and dissemination of seismological knowledge. It also favors the organization of this bureau under the Smithsonian Institution with the active co-operation of other scientific departments of the Government.

EARTHQUAKE INVESTIGATIONS

The following report was made by the Committee on Rift Belt Deformation, at the San Francisco meeting of the Seismological Society of America, March 2.

The most important fact brought to light by the investigation of the California earthquake of April 18, 1906, is that a condition of stress existed in the earth's crust antecedent to the rupture which produced the shock. This stress seems to have been effective as a slow tortional creep of the coastal portion of the middle Coast Ranges toward the northwest. It was relieved by a fault rupture along the San Andreas rift at the time of the earthquake, the fault-trace being certainly 190 and probably 270 miles in length. The relief was effected by a forward or northwesterly movement of the portion of the earth's crust lying to the southwest of the fault and a resilience or backward movement to the southeast of the portion lying to the northeast of the fault, the maximum horizontal relative displacement being 21 ft. The fact that similar displacements have repeatedly occurred along the San Andreas rift in time past is warrant for the belief that the stress operative in the earth's crust up to April 18, 1906, was only temporarily relieved by the fault of that date, that the stress is a secular condition of the region, and that the creep of the earth's crust which it induced will be renewed and will accumulate until it is again relieved at some future time by a rupture similar to that which occurred in 1906.

In view of this conclusion it is a matter of the utmost importance to geological science that the phenomena of creep should be most carefully studied. Such a study will doubtless extend through decades and generations owing to the slowness of the movement, and we can scarcely hope in our time to fully understand it. We may, however, attack the problem in the hope and reasonable expectation of arriving at results which will be of service to humanity. The first step toward this end is the determination of the distribution of the stress as manifested by the slow creep of the region and the measurement of its amount. This in the opinion of the committee may be best accomplished by establishing series of monuments extending out in a direction approximately normal to the San Andreas rift at suitable localities and determining their relative positions by careful survey from time to time. Each line of monuments should extend out where possible for at least 20 miles on either side of the rift and be composed of stable concrete piers spaced not more than two miles apart. In the opinion of the committee there should be at least three lines of monuments, one to be placed near the head of Tomales bay, one near the south end of the Bay of San Francisco, and one crossing the rift where it traverses the south side of the Mojave desert. The cost of installing these monuments and establishing their position in the first instance would be about $5000. The committee recommends that the Society make an effort to secure the money necessary for this purpose.

The Chainman mill at the Chainman property in the Ely district has been remodeled by the lessees, McGill & Willoughby, and is now crushing 30 tons of ore per day with the prospect of having this output doubled in a short time. The ore passes over a grizzly to a 6 by 12-in. crusher, the broken product uniting with the fine which is handled by a 6-ft. Chilean mill. From this the ore passes over a series of 4 by 8-ft. plates on which 15% of the assay value is saved, and through hydraulic classifiers to the settling and agitating tanks. The sand is shoveled from the settling tanks to cars and transferred to leaching tanks where it is treated with a 0.3% solution for five days. The slime is handled in a 100-ton air-agitating tank. Ordinary zinc shaving precipitation is used with an excellent recovery. The ore is taken from the Southern Cross claim of the Chainman group and assays from $6 to $20 per ton. It breaks easily and the cost of mining is placed at $1.30 per ton, with $1.75 additional for treatment at the mill, and $0.65 for transportation.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Electric Drill-Sharpeners

The Editor:

Sir—I note in your Johannesburg letter of March 12 the statement: "We are still hankering after an electric drill-sharpener to enable us to regulate the temperature with exactitude for the different classes of steel, but until this comes the oil furnace will continue to give satisfaction."

I venture to suggest that an electric drill-sharpener is already on the market. The Hoskins Manufacturing Co., of Detroit, makes two types of electric furnaces, each one of which is manufactured in both muffle and tube-chamber styles. These furnaces are heated by electrical resistance, and their temperature may be regulated with absolute accuracy by simply controlling the current through the resistance element. For heat treatment of drills and steel parts they have the fundamental advantage of producing the required temperature with entire freedom from products of combustion, which must necessarily accompany heat production from any other source of energy. The type FB furnaces made by this company are particularly applicable to the treatment of carbon steels; the type FC furnaces are similarly adapted to heating of all classes of high-speed steel. This latter type has the further advantage of having a reducing atmosphere within the chamber while in operation.

I hope that this information may prove of interest in the locality mentioned above.

H. RALPH BADGER.

Detroit, March 20.

Zinc Ore and the Tariff

The Editor:

Sir—The new tariff law which assesses a duty upon zinc has been in operation a sufficient length of time to warrant drawing conclusions as to its effect on zinc ore importations. Eighth months have elapsed since the law went into effect and during that time numerous inquiries have been made as to the result of the change. The duty is assessed upon a sliding scale; some ore is free and some pays up to one cent per pound on the metal content. The tax varies with the percentage of metal in the ore. Ores containing 10% and under are free; those containing from 15 to 20% pay ¼c. per pound of metal; those containing from 20 to 25% pay ½c.; and all ores containing over 25% zinc, are taxed 1c. per pound of metal content. On this basis a ton of 25% would pay $5 duty per short ton; the 20% ore would pay $2 duty per ton. As most of the ore in demand in this country is of higher grade than 25%, the maximum duty of one cent per pound is in fact collected.

Since the law was passed importations have not absolutely ceased as was predicted. Since the predictions were made by the enemies of the law its friends now view the situation as one warranting close inquiry. The following table gives the importations by months for the entire year of 1909. The two periods, before and after the law went into effect, are indicated. Long tons are used but the totals are reduced to short tons.

ZINC ORE IMPORTS FOR 1909

Months.	Long Tons.	Value.
January	9,096	$118,182
February	4,146	41,343
March	5,246	63,754
April	12,973	166,886
May	13,633	150,289
June	9,898	137,621
July	12,073	173,138
Total previous to tariff	67,065	$851,213
August	13,097	$203,740
September	2,438	35,174
October	4,809	65,857
November	7,507	109,182
December	6,819	101,509
Total after tariff was imposed	34,670	$515,462
Total for year	101,735	$1,367,675
Equivalent to short tons	113,010	1,367,675

According to these figures, imports have diminished. Previous to the imposition of the tariff the average monthly imports were 9580 long tons. After the tariff was imposed the average was only 6934 tons. This would indicate a decrease of from 15 to 20%. It will be noted that the heaviest imports were made the first month after the tariff was imposed. This was due to the effort to get the ore into the country before the law went into effect. Following this there was a marked drop in importations. This, in turn, was due to the need of making new contracts with the ore producers, and the necessary arrangements for payment of duties. It will be noted that after only two months the importations jumped to nearly 5000 tons from which they increased to about 7000 at the end of the year. January 1910 showed a reduction again to 5736 tons. This was due entirely to bad weather which interfered with shipments. The February shipments again reached 6925 tons and the March shipments, while not yet available, will presumably be still greater.

If the value of the imports, which ranges from $10 to $12 per ton, be taken into account, it is easy to understand why the importations continue heavy in the face of the duty. The average metal content of the ores is close to 36% zinc. The duty on 36% zinc would be $7.20 per ton. This added to the value of the ore gives $18.20 for 36% ore, or at the rate of $22 per ton for 40% standard zinc ore. This, with the freight rate of $5, makes the total cost of the ore laid down at American smelters $27 per ton; providing that the smelter pays the duty. Since the average price for 40% ore in the Joplin district during the period under consideration was about $27 per ton, it is evident that it is at least as cheap to buy ore in Mexico and pay the duty in addition to the price paid the Mexican ore-producer. It is known that as a matter of fact the duty is deducted usually from the price paid in Mexico. This gives the smelter a profit of from $4 to $5 per ton when he buys Mexican instead of Missouri ore. Had the rate been 1½c. per pound, as asked for by the Jop-

lin operators, the duty on the ore now imported would have amounted to $10.80 per ton instead of $7.20, thus making it more expensive to buy in Mexico if the duty were added to the price paid the Mexican ore-producer. If the duty were subtracted from the price paid to the Mexican ore-producer, it would have so reduced his profit as to have excluded him from the American market. The ore-producers of the Joplin district are now beginning to realize that in the compromise they did not secure the protection that they expected.

It is interesting to compare the imports with the production of the Joplin district. The following table gives the imports of zinc ores since 1904 and the production of the Joplin district in parallel columns with the ratio in percentage of imports to Joplin production.

Year.	Zinc imports. Tons.	Joplin production. Tons.	Import. Per cent.
1904.....	2,264	267,240	0.8
1905.....	22,137	252,435	8.7
1906.....	55,414	278,927	19.8
1907.....	103,117	286,587	35.9
1908.....	53,757	259,598	20.7
1909.....	114,850	301,206	38.1
Total	351,539	1,646,993	21.3
1910 (two mo.)	12,761	44,948	28.3

The rapidity with which importations have grown is apparent at a glance. From less than 1% of the Joplin output in 1904, they have grown to 38% in 1909. What is still more significant is the fact that the year 1909 was also one in which the first attempt was made to exclude the imports and the remedial measures were in force five months of the period of that year. The year 1910 has started with the imports practically equalling 28% of the Joplin production. It must be kept in mind that the zinc imports contain only 40% zinc while the Joplin ore assays close to 60%. The evidence seems conclusive that the duties assessed against zinc ore is not sufficiently high to prevent its importation. Moreover American zinc smelters will doubtless find it advantageous to keep up importations even if the cost per ton is slightly higher. In this manner they can depress the American ore market.

In addition to the imports of Mexican zinc ore the American supply has been greatly augmented during the past seven months by development of the zinc-ore deposits of the West. The tariff agitation drew attention to these deposits. It was the contention of all the smelters that the American ore-supply was insufficient to meet the demand. If there was such a demand the Western mine-owner decided he would profit by it, and all through the West there has been an increasing output of zinc ores. American smelters have encouraged this movement and Joplin zinc-ore producers now face the gravest competition they have ever had to meet, since Western zinc ores are produced largely as by-products and are cheaper than the high-grade Joplin ores.

On the other hand there have been inaugurated in Mexico two movements which will help to divert Mexican ore from our market. The Mexican Government has increased the freight rate on zinc ores from the mines to the American border and at the same time reduced rates to sea-ports where shipments are made to European points. This will encourage shipping zinc ores to Europe instead of America. There has been also agitation for the building of a zinc smelter at some suitable point in Mexico. The new oilfields are stated to afford promising conditions for such an enterprise but the promoters are urging its location near Torreon. Since the location of such a plant is largely a matter of suitable fuel in abundant quantities with good transportation, the promoters will doubtless be governed finally by the reports of their engineers.

OTTO RUHL.

Joplin, Missouri, April 6.

Ditch and Flume Information

The Editor:

Sir—I am trying to secure data as to the construction of a ditch to carry 2000 inches of water for hydraulic mining. A large portion of this (three miles and 21 rods), will need to be flumed. The main points I am trying to learn are the width and depth necessary to carry this volume of water, 2000 inches being equal to 50 second-feet, the grade as now surveyed being 16 ft. to 320 rods; and as to ditch and flume, the kind of material for fluming, that is, size of sills, posts, caps, and so forth, and how to build this. There are technical works upon almost every phase of mining, such as mine timbering, and the like. Is there not some work covering ditch and flume construction? I expect to install a pipe-line, giants, power-derricks, and other equipment, data as to costs and kinds of which I can figure out from the Hendy, Risdon, and Pelton bulletins, very satisfactorily, but I am 'up against it' on the ditch and flume proposition. Can you suggest ways and means by which I can get the information? I am not a technically educated man, but just one of the common people. As a heavy owner in, and entire manager of, the property, I am anxious to get off on the right foot. Any advice you can and will furnish me I will be thankful to you for, and willing to pay for the advice.

INQUIRER.

Holland, Oregon, April 2.

[The foregoing letter calls attention to a lack of definite information in the literature on hydraulic mining which reveals an opportunity for ambitious authors. It is necessary to add that the MINING AND SCIENTIFIC PRESS does not answer questions privately for pay, but prints its contributions for the benefit of all. Inquirer should consult an engineer for specific professional aid.—EDITOR].

Diaphragm Cones and Tube-Milling

The Editor:

Sir—Allow me to call your attention to a typographical error in my article on Caldecott cones in your issue of April 2. On page 485, top line, left hand column, the word 'sufficient' has been substituted for 'insufficient' resulting in a contrary meaning to that which should be conveyed. There is no warrant either for Fig. 1 being called a 'filter cone'. Diaphragm cone would be more correct, but that is not a matter likely to mislead anyone.

WALTER NEAL.

El Oro, Mexico, April 8.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Dividends by oil companies listed on the San Francisco exchange amounted to $683,679 in March and a total of $29,242,803 has been paid to date.

Feldspars are among the most widely distributed minerals and are constituents of nearly all rocks. The decomposition of feldspar has yielded a large part of the clay of the soil; also the mineral kaolin, an essential material for making fine pottery.

The Seine is the fourth largest river in France, ranking in size below the Loire, the Rhone, and the Garonne. Its drainage basin (30,370 sq. mi.) is larger than that of the Susquehanna (27,400), or of the Sacramento (27,100).

Engineers of the United States Geological Survey estimate the annual damage by floods in the United States at $100,000,000. It is too early, perhaps, to undertake to prevent or to diminish this immense loss, but its very magnitude invites a serious study of means of prevention, and the recent misfortune of France may lead to practical work that will serve as an object lesson to America.

Grounded overhead conductors, relief gaps on insulators, lightning rods supported on the transmission line structures or on separate structures along side, and station-type lightning arresters at points particularly exposed, are some of the principal preventive devices employed to protect high-tension transmission lines from injury by lightning, but none are completely successful.

Insurance on concrete buildings is always low. The report of the committee on insurance to the National Association of Cement Users showed that approximately 30% of the owners of concrete or reinforced concrete buildings carry no insurance, believing them to be practically fireproof. The matter has been taken up by a number of insurance companies and it is probable that more favorable rates will be made for this type of structure.

Molybdenum in lead ore interferes with its assay by the Guess method and it should be removed by treating the ore with nitric and sulphuric acids. This removes the molybdenum and other interfering elements and leaves the lead in the form of sulphate. In the Guess method the ore is treated with nitric acid and the lead is held in solution by the addition of ammonium nitrate. The solution is electrolized in the same beaker and the lead deposited as peroxide on the anode.

The Braden copper mines are located near Rancagua, Chile, about 80 miles from Santiago, and 200 miles from Valparaiso. The company owns 1200 acres of mineralized lands lying around the crater of an extinct volcano. Prospecting work has shown that the mineralization occurs around the entire periphery of the crater, some 14,000 ft. in length. The ores occur in compact masses. It is claimed that over 5,000,000 tons of ore, averaging 2.7% copper, have been developed. The orebodies vary from 80 to 250 ft. in width, and their depth is still undetermined.

The Chino Copper Co. is operating the old Santa Rita mines near Silver City, New Mexico. The property was formerly worked for high-grade ore, but is now being drilled with a view to development of low-grade copper. Some 200 holes have been put down. Of these 169 have found ore and 151 have entered into calculation of 'reserves'. The latter were estimated December 1 at 7,874,000 tons assaying 2.46% copper. The average thickness of the ore as shown by workings and drill holes was given at 82.9 ft., the over-burden at 76.5.

Power-site withdrawals on March 4, 1909, were in force covering public lands on 29 rivers in nine States. These withdrawals have since been reviewed by the Geological Survey, the form of withdrawal has been changed to include all entered as well as all vacant lands and the lands that were found to be not valuable for the purpose for which the withdrawal was made have been restored to entry. New withdrawals have been made along 97 rivers covering land not involved in previous withdrawals and increasing the total number of States affected to eleven. These power site withdrawals now cover about 1,300,000 acres of vacant public land and 200,000 acres of entered land.

Coal-land was sold under the old regulations at a maximum price per acre of $75; under the new regulations the maximum price per acre thus far fixed for any particular area is $465. The maximum valuation of a single township under the old regulations was $949,600; under the new regulations it is $9,206,894. Special efforts have been made to release from existing withdrawals all non-coal areas, and of the total area classified during the year ended March 4, amounting to 17,200,000 acres, much the larger part, or about 14,000,000 acres, has been classed as non-coal land. The sale price of the 3,436,000 acres classed as coal-land has been fixed at $191,490,000. The same land, if sold at the minimum price would have yielded $62,477,000.

In starting a roasting furnace the same precautions should be observed as in starting a reverberatory; it should be gradually warmed to dry it out, and the temperature slowly increased. This process should occupy from 7 to 14 days according to the size of the furnace and particular attention should be given to the tie-rods and buckstays, watching the expansion of the arch and when the maximum has been reached, tightening the tie-rods to bind the whole structure solid. Should a roasting furnace at any time require to be closed down, drop the dampers as low as possible, close all port holes and fire-doors to prevent cold air entering and retain all heat possible. Sudden expansion or contraction in furnace structures has very bad effects and must be prevented if possible.

FAIRBANKS, ALASKA

Quartz Prospects and Stamp-Mills. — Copper on Dry Creek. — Warm Weather Starts Placer Work. — New Type of Steam-Points.

Indications point here to a good season. Interest in quartz prospects is increasing rapidly since the recent mill-run on the 15 tons of rock from the Spaulding & Clough property and since Martin Harrais left for the outside the middle of March to bring in machinery for a 10-stamp mill this season. Mr. Harrais has abiding faith in the quartz discoveries and intends to build the mill at Chena, eight miles below Fairbanks, where connections by rail and water give good facilities for custom work. It is possible that Spaulding & Cough, who recently put 15 tons through the Fairbanks test-mill, will put in a plant of their own as their ore needs special treatment. At the recent run, it was found that $5.25 per ton was caught on the plates, $14.50 of free gold remained in the tailing, the concentrate represented $7.70 per ton, and a trifle over $21 was not released by crushing. This makes practically $50 ore. As the sacks were filled by shovel from the broken rock after blasting, there is no doubt but the ore sent in was a fair sample. This vein is from 3 to 4 ft. wide and has perfect walls. As the gold is extremely fine, it would seem that cyanidation after sliming would give a good extraction. A remarkable vein has been opened by the Butler-Petree company although work has been discontinued. The vein was struck in an adit and a raise of about 60 ft. driven to the surface. A shaft 170 ft. deep was also sunk. A 40-ft. drift along the vein at the bottom of the shaft shows the vein as strong and rich as above. It is understood that the rock assays about $32 per ton, about evenly divided between free gold and concentrate. The vein varies from 5 to 8 ft. wide. Across Chatham creek from this property, the Pioneer Quartz Mining Co.'s claim is being further prospected by Ringseth & Giske. At the end of a 250-ft. adit a cross-cut is being driven to pick up the vein shown in the shaft farther down the hill. Mr. Rhodes is still driving along the vein on his property on Bedrock creek, being in now about 400 ft. Near the face there is almost 4 ft. of solid quartz. Charles Crawford has a lease on a block of ground on this vein and is sinking at the mouth of the adit. He is down 50 ft. and has a lot of high-grade ore out for shipment. The vein continues strong at the bottom of the shaft. On Willow creek, the Tolovana properties show a bunch of stringers that yield a large percentage of high-grade ore. The gold is practically all free. Some of the richest specimens yet seen in this camp have come from here. Lennon & Liebermann are working this property at present and have a large amount of ore sacked for shipment. Fred Melius is working on the other slope of Willow creek and has found rich ore in a prospect shaft. The vein is from 2 to 3 ft. thick and assays well. Below this slope at the head of Cleary creek, Peter Steil is cross-cutting to pick up a vein found in a surface prospect. He is in 150 ft. Hirschberger, Buhl & Phipps are now sinking on a 3-ft. vein which crosses the saddle between Cleary and Eldorado creeks. Some 9½ grains were amalgamated from 4 lb. of rock, showing that the ore contains approximately $150 per ton in free gold. After sinking 50 ft. an adit will be run from the Eldorado side. This will give about 400 ft. of backs. An immense deposit of copper is reported from the Dry Creek country by the Cook Brothers who have been prospecting in that district for years. The outcrop is from 300 to 600 ft. wide and is traced for over a mile. A sample of croppings taken across a 400-ft. face gave 7.5% of copper after picking out the extra rich pieces. Bunches of chalcopyrite from a few inches to several feet through are found frequently. As the samples taken were croppings only, it is safe to say that below the oxidation zone much richer ore will be found. A mile from this orebody is an immense body of coal and the proposed railroad will pass within a short distance.

Unexpected warm weather has started the placer miners to work in getting ready to sluice. More plants are working on good pay than was expected last fall and the 1910 output should at least equal that of last season. On Chatanika and Cleary creeks alone, there are 46 dumps on top waiting for water. Some of the largest and richest dumps are on No. 4 and 5 Below Cleary where eight outfits have been hoisting all winter. Among these are Bullard & Aitken, Henry Riley, Max Altman, and Smith & McIntyre. Lower Engineer creek will be a heavy producer this season, the output promising to be even greater than last season. Cascaden & Jameson, Benson Bros. & Parker, Enstrom Bros., Lushbaugh & Sandstrom, Sam Hagan, Jorgensen & Co. and Porter & Van Winkle will all take out good pay. The famous 17 Goldstream just below will also be in the front rank. It is interesting to note the development of the steam-points which form so vital a part of

A Clean-up on Cleary Creek.

the mining outfit. From the sweater made of half-inch pipe has been developed the reinforced hydraulic pipe with point and head of tool-steel and patent clamps for holding the steam-hose. The most recent development is changing the tapering tool steel-point to a Burleigh bit, thus enabling the driver easily to go through hard bedrock or large rocks. This is just being introduced.

WASHINGTON, D. C.

Conservation Legislation.—Chamberlain's Speech. — New Bills.

That Congress is giving more serious thought to the public land question than ever before is in evidence daily in Washington, but that there will be any new legislation upon this momentous problem at the present session is far from certain. At least fifty bills on this subject have been introduced in both Houses, but practically none has got beyond the initial stage. The session is in its fifth month and is more than two-thirds over. Members of Congress are farther apart in their views than when the session began. The Public Lands Committee of the House is hopelessly split on the proposed law to authorize the President to make withdrawals and classifications of public lands. The Senate Committee on Public Lands has been deprived of its chairman, Knute Nelson, of Minnesota, because of his work investigating the Interior Department and Forestry Bureau. Despite this discouraging situation, Mr. Taft has not given up hope that laws will be enacted at this session along the lines of the nine conservation bills suggested by him. He had a serious talk recently with members of the Public Lands Committees from both

Houses and urged some action on the bills and placed them in the following order of importance: (1) withdrawal and classification of public lands; (2) conservation of coal lands; (3) conservation of water power; (4) conservation of oil lands; (5) conservation of phosphate lands. The meeting simply served to emphasize the difficulty of any attempt to harmonize various ideas on this legislation. There is great misunderstanding of conditions and few of the members are acquainted with the vast detail necessary to consideration of the subject. Eastern members are unfamiliar with conditions in the West and the representatives from the latter section encounter great difficulty in explaining the actual meaning of conservation as it relates to the people of their district. But one of the conservation bills has been reported from the Senate Committee on Public Lands. As amended, it reads as follows: "That the President may, at any time in his discretion, withdraw from settlement, location, sale, or entry any of the public lands of the United States and reserve the same for forestry, water-power sites, irrigation, classification of lands, or other public purposes, to be specified in the orders of withdrawals, and such withdrawals and regulations shall remain in force until revoked by him or by an act of Congress. The Secretary of the Interior shall report all such withdrawals to Congress at the beginning of its next regular session after the date of the withdrawals." George E. Chamberlain, Senator from Oregon, made a vigorous plea for this bill the other day in which he said he favored it for three reasons. First, the main principle involved, the right of the President to withdraw portions of the public domain from entry, settlement, or sale, had been approved by every department of the Government from the earliest days of the Republic. Second, the exercise of the power is necessary to protect, for the benefit of the whole people, what is left of the public domain from the result of legislative improvidence. Third, it is necessary to conserve the undisposed of and unappropriated natural resources. Relative to existing authority to make withdrawals Mr. Chamberlain said: "I have not been able to find where the authority was questioned until the point was raised by the Secretary of the Interior and possibly later by the President himself. It seems to me that a policy which has proved salutary in the past and has resulted in the prevention of the monopolization of many of the natural resources of the country ought not to have been lightly swept aside by this or any other administration." Mr. Chamberlain said that great frauds had been perpetrated through the preemption law and that the timber and stone act proved even worse. As a result of these measures, millions of acres of valuable public lands had gone into the hands of powerful corporations and syndicates. "There is no question," said Mr. Chamberlain, "but that through the instrumentality of the timber and stone act the most valuable timber in the country has gone into the hands of timber syndicates who are thus enabled to fix extortionate prices upon a product that enters into the everyday life of every man, woman, and child in the country. It may be insisted that their looting of the public domain has been made possible by laxity of administration; but Congress is not the less to blame, for these frauds were known of all men years ago, and nothing has ever been done to make them impossible by repealing the law, although repeal has been more than once recommended as the only panacea." Mr. Chamberlain's speech developed into a strong denunciation of those who oppose conservation of the natural resources. After referring to the inventory of natural resources made by the Commission under President Roosevelt, Mr. Chamberlain said: "Not only did Congress not then see fit to enact any legislation therein recommended, but unfortunately declined to print the report in sufficient numbers for its adequate distribution among the people. More disastrous than this, however, was the Congressional enactment forbidding this or other executive commissions from pursuing their important work in the service of the people. This action, plainly designed to wipe out the national conservation commission, accomplished its purpose. It put an end to the activities of that commission, removing the only national organization which was dealing with the conservation question as a whole. Thus was presented the strange spectacle of a national wide movement, inaugurated by the governors of the States, the presidents of great organizations of our national industries, and other distinguished citizens, and heartily endorsed by the people of the country, by legislative enactment denied not only an appropriation, but even permission to continue its work."

Recent bills dealing with the public lands question have been introduced into Congress as follows: By Reed Smoot, Senator from Utah, to provide for the granting by the Secretary of the Interior of permits to explore and prospect for oil and gas on unappropriated and withdrawn lands; a second authorizing the President to withdraw from all forms of settlement, entry, or other disposition any lands which are or may become chiefly valuable for development of water-power, and providing for the acquisition by any State or Territory, under certain conditions, of any lands so withdrawn, and for other purposes; by Henry Cabot Lodge, Senator from Massachusetts, to amend the mining laws of the Philippines; by George A. Bartlett, representative from Tonopah, Nevada, defining the manner in which deposits of borax, borate of lime, borate of soda, and borate material may be acquired; by Asle J. Gronna, representative from North Dakota, to provide for the classification of the public lands of the United States; a second to authorize the disposal of phosphate, oil, asphaltum, or natural gas; a third to provide for the disposal of coal and coal lands; by James Wickersham, delegate from Alaska, to create, establish, and enforce a miner's labor lien in the territory of Alaska, and for other purposes; by Charles E. Pickett, representative from Iowa, to authorize the President of the United States to make withdrawals of areas of public land for classification and other purposes, pending report and recommendation to Congress.

MEXICO

Teziutlan Copper.—Zimapan, Hidalgo. — Yaqui River Railroad. —Transvaal Copper.—Lucky Tiger.— El Tigre. — Taxco & Guerrero.

The Teziutlán Copper Mining & Smelting Co., owning property in the State of Puebla, which has smelted no ore since the drop in copper prices, will blow in before the end of April. The company is controlled by the Robert S. Towne interests. D. C. Brown, the Towne manager in Mexico, is now at the Teziutlán camp and will remain there until the smelter is in commission. Since the suspension of smelting the Teziutlán smelter has been entirely rebuilt, and it is now one of the most modern plants in the Republic. The building is largely of structural steel, and there are two 500-ton Robertson-type jacket furnaces, with converters and other equipment. All the machinery is electrically operated, power for the smelter and mines being secured from a 3000-hp. hydro-electric plant 3 miles north of the smelting plant. Blister copper will be produced, and the product shipped to Perth Amboy for refining. Shipments will be made through the port of Vera Cruz until such time as the projected Teziutlán-Nautla railroad is built, when the company will have a direct outlet through the Gulf port of Nautla. Development has been continued steadily since smelting was suspended, and there is now an immense tonnage in sight in the mines, and supplies for several months in the ore-bins at the smelter. It is said that stoping can be done at a rate of at least 10,000 metric tons per month. The company owns the big Ocotes copper mine in the State of Oaxaca, and development is now in progress there. Some Ocotes ore will be shipped to the Teziutlán smelter. A 1400-hp. hydro-electric plant will be installed on the Sola river in Oaxaca to furnish power for operations at the Ocotes mine. Within the next few months the Teziutlán company will again take rank as one of the principal copper producers of Mexico.

The Towne interests are extensively developing the Flojonales copper mines in the Zimapán district in the State of Hidalgo, and there is promise of heavy copper production there. The mines were taken over last year at the expiration of an option. The completion of the Pachuca-Zima-

pán railroad, now under construction by the Honey interests, will greatly reduce the distance to modern transportation, and a branch may be built by the Towne interests. The installation of a copper furnace at the Towne custom smelter in San Luis Potosí, to handle Flojonales ores principally, is now under consideration, although shipments may be made to the Tezintlán plant.

The roadbed of the Southern Pacific's Yaqui river line has been completed through the canyons south of Nacozari, and south of Cumpas the work will be comparatively easy. The concession requires the completion of the line from Nacozari to Cumpas in July, but if necessary it is probable that an extension can be secured. The Transvaal Copper Co., which has money of Cincinnati brewing interests behind it, plans to build a railroad from Cumpas, where it has a smelter, to the mines, a distance of about 40 miles west. The mines are now connected with Cumpas by an excellent wagon-road that is said to have cost ₱400,000. Just beyond the Transvaal properties are the mines of the Minneapolis Copper Co., said to promise heavy production, and beyond them the Washington mine, purchased last year by James Douglas, L. D. Ricketts, and others for ₱400,000. The Washington is a big low-grade copper property. The Duluth-Moctezuma Co., operating in the Moctezuma district, has realized $22,000 from 5 carloads of silver ore shipped to Douglas. The value of the ore was $56,000. The Lucky Tiger Gold Mining Co. has declined to double the

Travel in the Yaqui Country.

capacity of its concentrating plant at the rich El Tigre mine, and plans for securing additional and cheaper power are being studied. An oil-burning plant at either Izábal or Douglas, with electric transmission to the properties, and a hydro-electric plant on the Bavispe river, are under consideration. Work on a cyanide plant at El Tigre was commenced a short time ago. It is reported that the Ryall exploration concession, covering about 1,500,000 acres of mineral land in the Yaqui river region of Sonora, will expire on April 24. The new mining law of Mexico provides against the renewal of such blanket concessions, and the granting of new ones. The concession is now held by the Pacific Smelting & Milling Co., the $8,000,000 concern that last year succeeded the Douglas Copper Co. and allied corporations. Recently suit to recover an interest in the Ryall concession and all mineral land taken up under it was filed in New York by Mrs. Metta F. Merchant, a daughter of the late James McCallum, who was one of the men originally concerned in the big exploration grant.

The Sultepec Electric Light & Power Co. has agreed to transmit power into the old Taxco district of Guerrero under a guarantee of 600 hp. A guarantee for a greater amount is said to be certain, and the comparatively cheap power will play an important part in reviving mining and milling in that mining region. The Atlixtaca Mining Co., in which Italian capital is interested, is preparing a site for a cyanide annex. Cyanide tests have shown satisfactory results. Frank Olendorf, who has been making zinc shipments from the Taxco district for some time, has interested American capital in plans for the erection of a zinc separating plant.

TORONTO, CANADA

Lignite near Cochrane.—Cobalt News.—Peterson Lake. — Porcupine.—Government Testing Plant. — Chibougamou Exploration.

Considerable excitement was caused in mining circles about the end of March by the announcement that coal in large quantities had been discovered in northern Ontario, west of Cochrane and about 60 miles north of the Grand Trunk Pacific Railway route. The deposits are siutated along the banks of the Metagama river, the high bluffs of which are thickly seamed with coal. About 20 square miles has been staked, each claim comprising a square mile, but not including a right to other mineral which may be found. Numerous prospecting parties have left for the region and syndicates are being organized to develop the deposits. The officials of the Ontario Department of Mines were not at first disposed to attach much importance to the discovery. A sample of the mineral sent to the Department proved on analysis to be lignite, and there is no authentic statement as to the existence of bituminous or anthracite coal in that region. The occurrence of lignite in that part of the country has been known for many years, Robert Bell having reported deposits on Coal brook anu the Missanabie river, in the report of the Canadian Geological Survey 1875-77. The subject is dealt with more exhaustively in a paper by James Mackintosh Bell, published in the annual report of the Ontario Bureau of Mines for 1904, on the economic resources of the Moose River basin. The coal is declared to be of excellent quality, analyses showing that it will make good steam fuel. The present discoveries therefore simply indicate an extension of the field and a wider distribution of the lignite than was previously known. While the cost of transportation will operate as a bar to an extended market, the lignite will be available for local domestic use, and probably will find some market as a steam coal when the region becomes settled. In the meantime there appears to be little opportunity for its successful exploitation commercially.

The Cobalt shipments for the first three months of the year amounted to 7069 tons. As the total shipments for 1909 were 30,098 tons, this indicates a slight falling off in the output, which will doubtless be more than made up when the cheap power now obtainable is in full operation. The shipments for the week ending April 1 were 844 tons. There were two new shippers on the list, the Harrgraves with 20 tons, and the Lucky Godfrey of Elk Lake, 27 tons. The latter sent out the first full car of ore shipped from the Elk Lake district proper. Another Elk Lake mine which bids fair shortly to rank as a producer is the Moosehorn. The shaft is down 125 ft. and 480 ft. of driving and cross-cutting has been done. Rich ore was struck some weeks ago about 385 ft. from the shaft and a winze will be sunk from this point to a depth of 250 ft. The company has installed a new 6-drill compressor.

The lawsuit between the Peterson Lake and Nova Scotia mining companies of Cobalt has been decided in favor of the latter. The dispute was over a strip of land which the Nova Scotia company, which leases a portion of the Peterson Lake location under a royalty, claims should have been included in its holding. The judge ruled that though the land was not covered by the description in the lease it was intended to be granted, and ordered a rectification of the case. On the Little Nipissing property a 3-in. smaltite vein carrying native silver, has been found at the bottom of the winze at a depth of 239 ft. The Bailey mine has been started again with power from the Montreal river. Stoping has been commenced on No. 2 vein, which is about 2 ft. wide, with ore carrying 1000 oz. silver per ton. At the Ophir good ore is being taken out at the 200-ft. level where the vein runs from 6 to 8 in. wide assaying about 2000 oz. silver per ton. The City of Cobalt, A. S. Stevens, manager, has closed a contract with the Northern Customs concentrator for the milling of a large tonnage of low-grade ore.

Large shipments of machinery are going forward to Porcupine. The syndicate that has acquired the Wilson property, on which 70 men are employed, is geting in 17 carloads. The Scottish Ontario is putting in a steam-hoist and boilers, camp buildings are completed, and the

rock removed in development is being sacked for shipment to Scotland for testing in the company's laboratory. A stamp-mill will not be put in until the company has 5000 tons ready for treating on hand. The Canadian Department of Mines announces that an experimental ore concentrating plant will be established at Ottawa to demonstrate methods of treating ores of all kinds. It will be operated in connection with the new experimental peat-plant. The Quebec Government has undertaken an examination into the mineral resources of the Chibougamou district, and an advance party carrying supplies and equipment for the expedition has set out. It will be followed in a few days by A. E. Barlow of Montreal and Mr. Quillin of Queen's University, Kingston, Ontario. The additional 1000 hp. turned over the wires of the Cohalt Power Co. permits the mill at the Temiskaming to keep the complete battery of 30 stamps dropping continuously.

JOHANNESBURG, TRANSVAAL

Big Mines to the Fore.—State Mines Flotation.—Cinderella Consolidated Amalgamation.—Crown Mines Annual Meeting. — Premier Diamonds.

Your correspondent is in the proud position this mail of being able to discuss several matters of topical interest without descending to trivialities. There is nothing petty in recent events. On the contrary, there have been so many 'big things' in evidence, that one has almost yearned for the reappearance of the controversy on 'fracture planes' in stopes, to relieve the solemnity of current history. There has been a gigantic flotation, with a huge name—the Government Gold Mining Areas (Modderfontein) Consolidated, Ltd. There has been a great amalgamation, resulting in the creation of the Cinderella Consolidated Gold Mines—a potential 'Crown Mines', in the opinion of the promoters, a distinctly latent one in mine. The Crown Mines, Ltd. has held its annual meeting, where some interesting points were announced as to the progress of the world's greatest gold mine. The Premier Diamond Mining Co. has also held its annual meeting, where details were given of the unparalleled scale of operations attained and where A. Wagner made a stupendous speech. The flotation referred to followed disposal of the mining rights of the great area in the Far East Rand held by the Government. The area consists of 2633 claims* on Modderfontein No. 167—the magnitude of which may be well expressed by the fact that it was often considered best to equip or mine on the basis roughly of one stamp per claim in the days of 5-ton stamp-duties. Tenders were invited to work this ground. The Government puts up no money for capital expenditure and takes no risks. It demanded minimum renumeration in a tax based on a sliding scale, ranging from 10 to 50%. The percentage is determined by the ratio between profit and yield. For example, if the yield is 30s. and the profit 10s., the tax will be 33.3% of the profit (including the regular 10% tax due by all mines). The successful tenderers, Barnato Brothers, offered an additional surtax, also on a sliding scale. It was stipulated by the Government that a certain proportion of the shares should be offered for public subscription at par and as a result of this provision, the prospectus has already been issued. The company's capital is £1,400,000—all working capital; 1,225,000 shares at £1, in full or partly paid up, have been subscribed by the promoters, leaving 175,000 shares that are offered at par to bona fide residents of the Transvall. Applications are to be received for not less than 10 shares and not more than 400. The area being one of good promise, where the yield should range from 24 to 28s. per ton and profits from 7 to 10s., there will undoubtedly be a big rush for these shares and the allotment proportion is not likely to be big, in the case of applications for the maximum. The small applications will probably be satisfied in full, in order to popularize this scheme of State mining by proxy. The Government is also busy upon some other of its holdings in the Far East Rand and is diamond drilling to determine reef contours to the east of the Modderfontein 'B' gold mines. Possibly this area will be worked by the State more directly and utilized as a training school for miners. The General Mining & Finance Corporation is trying its hand at something 'huge', and has fallen an easy victim to the combined fascinations of a big claim area and a calculating machine. The amalgamation emerges from the Cinderella Deep, Ltd., which is a 100-stamp deep-deep mine with a single shaft. Because the Cinderella Consolidated is to have over 2000 claims and because a central mill ultimately of 200,000 tons per month is virtually promised, the error may be made in regarding it as another East Rand Proprietary or Crown Mines. Unfortunately, the producing nucleus is very small in the case of the new amalgamation, and we are dealing with ultra-optimistic estimates, instead of merely an improvement in conditions to be effected by joint operation. The Cinderella Consolidated is to be equipped with two new vertical shafts (over 3000 ft.), and a central mill of 100,000 tons per month. The cash provided is £681,000, which is inadequate for the completion of the scheme outlined. The Crown Mines, Ltd., a vast concern—one of actualities, as opposed to the foregoing acreage of 'potentialities'—held its first annual meeting on March 8. The group was only run under single control after July 1, so that the first half of the year is represented by the results of the constituent companies. Comparing these with the figures for the united concern for the latter half, we get the following summary:

	Constituent Companies Jan. to June	Crown Mines, Ltd. July to Dec.
Tons milled	829,473	740,924
Yield per ton	32s.7d.	33s.9d.
Cost per ton	15s.1½d.	16s.10d.
Total profit	£723,027	£627,135
Development per month (average)	2839 ft.	3205 ft.

Apart from the natural difficulties involved in reorganization and centrallzation, labor troubles are almost entirely responsible for the poorer showing of the amalgamated company. There is no reason to question the beneficial influence of the amalgamation because there have been temporary troubles. Single-mill properties have suffered severely enough during the same period. G. E. Webber, in his report as consulting engineer, gives the ore reserve estimate at 3,916,583 tons at 7.7 dwt., and notes that the additions to reduction works in hand will bring the crushing capacity to about 157,000 tons per month. The reserve thus forms practically a two-years' supply.

The chairman of the Premier Diamond Mining Co. had another year of huge production and comparatively poor financial results to discuss before shareholders at the recent annual meeting. The annual report contains some well tabulated statistics which demonstrate the tendencies of progress more convincingly than any general statement in words. The principal features may be summarized as below:

Year to Oct. 31.	Loads of 16 cu. ft. washed.	Yield per load, carats.	Value per carat.	Value per load.	Cost per load.
1903	76,931	1.29	27s.8d.	35s.7d.	4s.7.2d.
1904	939,265	0.798	23s.1d.	18s.5d.	2s.7.6d.
1905	1,388,071	0.609	23s.6d.	14s.4d.	3s.3.4d.
1906	2,988,471	0.301	28s.5d.	8s.7d.	3s.5.7d.
1907	6,538,669	0.290	18s.0d.	5s.2¼d.	2s.4.1d.
1908	8,058,844	0.258	14s.9d.	3s.9.7d.	1s.10.2d.
1909	7,517,793	0.249	12s.6d.	3s.1.4d.	1s.11.4d.

The relation between the last two columns is particularly noteworthy, it being apparent that it is not long since the cost per load washed exceeded the present value recovered per load. The speed of washing will increase rather than diminish. Providing it gets the labor, the company will be treating 850,000 loads per month shortly, and 1,000,000 loads before the end of the year. A. Wagner again delivered his customary onslaught upon De Beers and the New Jagersfontein, from which we must conclude that the world's diamond market, from the producers' standpoint, is influenced by the same little feelings of personal antagonism that bear on the sale of peas or pumpkins in a country town.

*A Transvaal reef claim equals 64,025 English square feet, or 1.47 acres.

NEW YORK

Porcupine and Cobalt News.—Copper Boom Deflated. — General Development Co. Option Pacific Smelting & Mining.

The keenest interest in mining circles at the present moment is in Porcupine. The one feature, perhaps, most deserving of comment is the public attitude and the comparisons constantly drawn between the intense interest shown in any news from this most recent gold discovery and the apathy displayed toward Cobalt. There was never a better illustration of the old adage that mankind takes more pleasure in pursuit than in possession. Cobalt is just getting the power turned on literally and figuratively; electric current and air are just available; both are to be used in increasing the production of the mines already shipping and in prospecting. The coming summer will, beyond question, be the busiest, best, and most profitable season Cobalt has yet seen, but it is equally beyond question that no new discoveries, no widening of the producing territory could revive or create any enthusiastic interest in Cobalt. On the other hand prospectors and miners are ablaze with excitement over the possibility of gold discoveries. A find was reported to have been made at Caribou Lake some 12 miles from milepost 170 on the Temiskaming & Northern Ontario railroad about 30 miles southeast of Porcupine. The trails are almost impossible owing to an early spring. Yet 500 men took chances over an almost unbroken trail 'through the bush' as the Canuck puts it, in the hope that a real strike had been made. It proved a false alarm. In the Porcupine district some progress has been made. Five outfits were fortunate enough to get in before the snow and ice roads broke up. On the Timmins property two 60-hp. engines and a 6-drill compressor are being set up. The shaft on this property is down 70 ft.; one shipment of 30 tons of ore has been sent out, part of it went to the Kingston School of Mines, and the balance to the Perth Amboy refinery. The assays returned from the first shipment showed from $750 to $2000 per ton. The returns from the refinery are not yet available. The syndicate headed by Ambrose Monell, of the International Nickel Co., has about 75 men at work on its property which is known as the Wilson ground and boilers and compressors are being set up. The Crown Chartered Co., operated by New York men, is also installing a power-plant and a sawmill. A flood of promotions may be expected during the summer should any of the development now under way result in making a real gold mine.

For the present at least the copper boom is deflated, if not collapsed. There are several important factors in the copper situation at the moment. First, and of overwhelming importance, is the growing stock of metal. The report of the Copper Producers' Association covering the month of March was exceedingly disappointing. It was expected that some increase in production would be shown, the demand during the month being good, but the worst that was looked for was a parity between producer and consumer. The increase in the surplus, therefore, of 16,636,882 lb. was a distinct setback. While tobacco, oil, and copper may, off hand, be supposed to have little in common, the action of the Supreme Court of the United States in calling for a reargument of the Standard Oil and American Tobacco Co. cases had a distinctly adverse effect upon the copper stocks while affecting almost all other securities in an opposite manner. The greater part of the public enthusiasm for 'coppers' has been founded on the belief that an all important merger was to be made, and opportunities for profits might and probably would be created in gathering up various properties. Now it is admitted on all hands that there will be no copper merger until the law relating to combinations or trusts is determined, which it will probably not be for at least a year. In the meantime the Granby episode, which is as yet without any satisfactory explanation, has helped to cool the public ardor. It is said that the real reason for the decline in Granby is high copper costs, and inability to show any profit on a 13c. copper market. It must be added also that the general public has not the patience required to wait during the four to seven years needed for the making of a big low-grade copper mine and a shrinkage aggregating a staggering total of nearly $200,000,000 on only 21 of the leading issues in the copper list means that the smaller investor is not to be held in line. Conditions must be radically improved either by curtailment or by the forced shutting down of the higher-cost producers before the public can be brought back into coppers. An increased production from the Phelps-Dodge Co. so large as to indicate a total for the coming year of more than 140,000,000 lb., together with a recent announcement of the Calumet & Hecla to the effect that the present market is very satisfactory so far as it is concerned as the company can make a reasonable profit on 13c. copper, holds out little hope for any agreement to curtail production. The General Development Co. has taken an option for examination of the properties controlled by the Pacific Smelting & Mining Co., a re-organization of the Douglas Copper Co. The properties, which are controlled through complicated re-organizations, consist of some 494 acres of mineral ground in the Alamos district, Sonora, Mexico, and the Pacific Smelting & Refining Co. smelter at Fundicion. The option is said to be on a basis of $600,000 for control of the Pacific Smelting & Mining Co. The various organizations as they stand appear to be involved past comprehension, but presumably the Pacific Smelting & Mining Co. holds the control. Theodore Douglas and Russell T. Connell, who is acting for the Lewisohn interests, are on their way for Mexico to make a thorough examination of the property and equipment.

BUTTE, MONTANA

Washoe Copper Co.—Butte-Ballaklava.—Tuolumne-North Butte.

The Washoe Copper Co. and the Big Blackfoot Lumber Co., Amalgamated subsidiaries, have accepted the Anaconda proposals. The Blackfoot was recently reorganized and its capitalization increased to $25,000,000. The Washoe company will receive 380,000 shares of the new Anaconda stock. The company owns the large smelting plant at Anaconda, and some good mines at Butte. Its producing mines include the Moonlight, Clear Grit, Cambers, and Poulin. It also owns coal lands at Bear Creek and Red Lodge, and a controlling interest in the Cokedale Coal Co. The Washoe company produced last year about 80,000,000 lb. of copper. The smelter is leased to the Anaconda company, but the Amalgamated furnished the funds for building it and holds a claim against the Washoe company for nearly $8,000,000. The Butte-Ballaklava Copper Co. will shortly be prepared to resume mining and shipping ore. A few days ago the west drift on the 800-ft. level opened a fine body of copper glace. The vein itself is about 9 ft. wide and 2 ft. of it consists of copper glace. The whole face of the drift is glance mixed with ore of a lower grade. In the east drift on the same vein the orebody is 11 ft. wide, and averages 10% copper and 20 oz. silver per ton. The same vein is being opened on the 900, 1000, and 1200-ft. levels. Owing to the limited capacity of the old hoisting engine only the ore that is taken out in the course of development is being brought to the surface, but from that the company is making occasional shipments. The new hoist, with double drum and capacity to work to 2000 ft., will be in commission as soon as the 300-hp. electric motor can be installed. It is said that the Tuolumne company has been assured that whatever claim the North Butte company may have on the strip of ground secured some time ago, no effort will be made to interfere. The ore being taken from the 2000 and 2200-ft. levels of the North Butte is averaging between 5 and 6% copper, and is being mined at a small profit. The company at the present time is taking out about 1200 tons of ore per day, which is between 200 and 300 tons per day less than before the engineers' strike. The Boston & Montana properties are being worked to practically their full capacity and the company's smelter at Great Falls is receiving about all the ore it can handle from these mines. On the lower levels of the Leonard some very valuable covellite has been encountered. Samples have been placed on exhibition in this city and they are attracting great attention from mining men.

General Mining News

ALASKA

(Special Correspondence).—The steamship *Northland* has just arrived at Ketchikan with a compressor plant for the Goodroe mine in this district and the Rogers property at Hoiiis. The latter is one of the new producers of the district and is stoping a good grade of gold ore on the 100-ft. level while the shaft has reached the 200 opening milling ore the entire distance.——Several new prospects are being opened with good results though the unusually heavy snows have hindered the work. The report of the Alaskan

The Alaska Perseverance Mill, Juneau.

United Gold Mining Co. for the month ended March 15, states that the Ready Bullion mill ran 26 days and the 700 Ft. Claim mill ran 21 days 9 hours. The mills crushed 28,085 tons of ore, recovered $35,659 worth of free gold, 520 tons of concentrate valued at $26,822, and $1805 worth of base bullion. The yield per ton milled averaged $2.30.

Ketchikan, April 11.

ARIZONA

COCHISE COUNTY

The El Tigre Mining Co. is contemplating the erection of a central power plant at Douglas which will furnish power for the proposed cyanide plant and electric line between Douglas and the mine. The line will not only handle the concentrate from the high-grade ore at the mine but would also serve the North Tigre, Antigua, Fortuna, South Tigre, and Cinco de Mayo mines.——At the Bisbee Extension property the shaft has been stopped at the 800-ft. level and drifts started on the 700 as the water was coming into the shaft too fast for the pumps to handle. A new boiler has been ordered and oil burners will be installed in the old ones the oil being hauled from Lewis Springs by wagon. ——Myers & Bland netted $22 per ton on a shipment of 14 tons to the El Paso smelter from the Scott & Crawford mine at Paradise which they are operating under lease.—— The Royal Guard Mining Co. has been organized to take over the properties of the Old Guard Mining Co. in the Tombstone district. New machinery will be installed and the mine reopened under the management of Frank L. Fowler.

GILA COUNTY

(Special Correspondence).—The Inspiration orebody as indicated by the underground and churn-drill work so far is 3000 ft. long, the maximum width being about 800 ft.—— J. Parke Channing, consulting engineer and vice president of the Miami Copper Co., has just given an interview in Globe in which he said that the orebody of the New Keystone Copper Co. is undulating, following the topography of the schist underlying the porphyry and that while the results of the underground work and of the churn drilling have been very satisfactory, the work has not yet been sufficiently correlated to make estimates of tonnage advisable. Mr. Channing estimates that in two months the various connections necessary for accurate figures will be made. Regarding the churn-drill work, he said that two holes just put down on the Philadelphia group have given negative results. Mr. Channing stated that undoubtedly a large body of ore assaying over 2% will be developed.—— Three drifts are being driven in the Live Oak orebody on the 300-ft. level. The vertical shaft has been sunk 65 ft. below the third level and is bottomed in chalcocite ore of good grade. The churn-drill recently purchased has just begun work at the junctions of drifts No. 308 and 311, 450 ft. west of the shaft.

Globe, April 15.

GRAHAM COUNTY

The churn-drill on the Celtic group of the Arizona-Morenci Copper Co. is down over 700 ft., and new cable has been shipped to the property to continue the hole to 1000 ft. Results have been extremely favorable and the company has ordered several other drills to facilitate the work. J. O. Baylor is manager.——The mill recently erected at the Gold Belt mine is running 12 hours per day with satisfactory results.——The New York-Arizona Copper & Gold Co. is preparing to erect a mill on its group in the Morenci district.

YAVAPAI COUNTY

(Special Correspondence).—M. S. Masson, chief engineer for the Electric Operating Construction Co., of New York, has just completed a transaction whereby the Arizona Power Co. acquires the holdings of the Prescott Electric Co. and the Prescott Gas Co., of this city. The resident manager of these companies will be M. V. Watson.——The Humboldt Smelter was blown in at 1 o'clock April 16. The entire plant has been remodeled and new steel buildings erected.

Prescott, April 18.

The Alturus group between Walker and Poland has been sold to Charles B. Foley of Mercur. An adit has been driven to the vein cutting it at a depth of 315 ft. and development carried on from this that blocks out about 40,000 tons of ore. The ore is 12 ft. wide at its maximum and is all suitable for cyanide treatment.——No definite figures have been given out by the management of the United Verde Extention as to the extent of the recent discovery but assays of the ore have run about 15% copper with $10 gold per ton and a small amount of silver.——In the Silver Mountain district 30 miles north of Wickenburg a rich vein has been opened in the Monte Carlo property at a depth of 65 ft. A small stampede has been started and a number of claims staked as the result of the assays.

YUMA COUNTY

The Carbonate Hill shaft of the Tank Pass Consolidated Mines Co. near Salome is down 125 ft. and is being sunk to the 250-ft. level. At the 100-ft. level a cross-cut was driven to the ore and a drift started toward the centre of the hill while two drifts are being driven on the vein from its outcrop.

CALIFORNIA

AMADOR COUNTY

The work of reopening the Ross mine near Sutter Creek has been started under the direction of L. R. Poundstone. ——Since the recent discovery in the foot-wall of the South Eureka local interests are planning to resume work at the Lincoln mine. This was diamond-drilled some time ago with unsatisfactory results but the finding of the ore mentioned has led to a belief that similar ore might be found in the Lincoln.——At the Central Eureka work is continued in the shaft. The cross-cut connecting the Central and South Eureka shafts has been completed and much better ventilation obtained.

CALAVERAS COUNTY

The Swiss Gold Mining Co. has been organized to reopen the old Swiss and Fine Gold mines at Rail Road Flat which have been idle since 1907. The vein is 4 ft. wide and assays from $6 to $10 per ton. The property is equipped with a 10-stamp mill and has built excellent accommodations for the men.——Owing to the shortage of power the mill at the Sheep Ranch mine is only running 16 hours per day. The stamps are dropping on ore from the dumps.

NEVADA COUNTY

The Central Consolidated, on Banner mountain, in the

Nevada City district, has completed the installation of 1000 ft. of cable and a new skip. The company at present is confining its work to blocking out ore on the levels already opened.——The installation of the new machinery at the Mountaineer has been completed and the big hoist started. The ore is now raised in 3-ton self-dumping skips which empty into cars at the landing.

PLACER COUNTY

W. F. Morris is opening the old workings of the Pioneer mine below Damascus. This is one of the old mines with a good production record though it is thought that considerable fair ore was left in the old stopes by the early-day workers.——W. W. Bissell has cross-cut the bedrock at the Excelsior group and is now working in the channel. The group embraces the Iowa Hill townsite.——The ore recently opened at the Jupiter mine is said to run as high as $20 per car.

PLUMAS COUNTY

Work at the Engle copper mine, in Light's canyon, is being carried ahead rapidly. A small force of men is employed at the saw-mill which will soon be cutting lumber for the mine buildings, and the castings for the smelter are being hauled to the mine. The company is blocking out a large amount of ore in the mine, and will be in a position to keep the smelter busy as soon as it is ready for operation.

SHASTA COUNTY

(Special Correspondence).—It is announced that the Mammoth Copper Co. will have its bag-house installed by July 1. The annex will be erected by the American Bridge Co.——Developments are progressing steadily at the Milkmaid with the 10-stamp mill yielding $15,000 to $20,000 per month. Clifford Wiegel, former owner of the Central mine, has been appointed superintendent.——A small force of men is employed at the Mad Ox property near Stella. Al Egerton is superintendent.——A call for an assessment of $1.25 per share has been issued by the First National Copper Co., controlling the Balaklala Copper Co. It is payable on or before May 10. Stockholders of record April 12 are subject to this call upon the unpaid balance of par value of their shares.——The Heroult electric iron smelter is ready for an extended run. A carload of graphite electrodes is on the way from the East which will enable operations to be conducted steadily. The management states that an excellent demand prevails for the product.

Redding, April 18.

The Balaklala Copper Co. recently requested an extention of time from the Shasta County Farmers' Protective Association in which to complete the installation of the Cottrell process for destroying smelter fume at the company's plant at Coram. This was refused by the association on the grounds that if the extention, from July 1 to October 1, were granted the crops for the year would receive no benefit from the installation.——The Pittsburg & Mount Shasta Gold Mining Co. is shipping ore from the Little Nellie mine on the Iron Mountain railroad to the Mammoth smelter.

SIERRA COUNTY

Homer Gould and Edward Pegg, of Downieville, have secured a bond on the Oakes mine in Sailor ravine.——F. A. Gowing, of Oakland, has taken the Standard mine three miles from Downieville under bond. Considerable high-grade ore has been taken from the property and a number of shipments of rich concentrate made. Twelve tons of ore which is expected to run about $12,000 per ton has been taken to the York mill to be treated.——A contract has been let to drive a 100-ft. adit on the Slattery group near Forest. ——The shaft of the Poker Flat Mining Co. is now down 238 ft., and is still in lava.——At the property of Elmer Mott, on Rock creek, a raise is to be started to open the gravel.——Work is to be resumed on the Runyan claims in Hungry Mouth ravine.

TRINITY COUNTY

The new machinery at the Lappin has been started and the machine-drills are doing excellent work in the mine. Frank Hollingsworth is superintendent.——Six men have been started at the Yellow Jacket mine and two adits will be driven to open the ore.——Operations are to be resumed this month at the Oversight mine on Yellow Jacket creek. ——It is reported that Fred Baudry has purchased the Poverty Slide hydraulic mine at Trinity Center and the water resources will be increased.

TUOLUMNE COUNTY

(Special Correspondence).—A rich pocket was opened last week in the Mohrman mine, south of Big Oak Flat, over $2000 being taken out in a few days. The property adjoins the Eureka mine on the east and the Red Jacket on the west and is worked under lease by N. W. Hilliard. ——The work of cleaning and retimbering the shaft and adit at the Sunnyside mine and the repairing of the mill and other machinery has been completed and development commenced.——Development work will be commenced at the Laguira mine, in the Groveland district, within a week, when repairing the shaft, 125 ft. deep, will be completed. ——It is reported that the Jumper mine will soon again be actively worked and that a new shaft will probably be sunk.——The Central Mother Lode Mining Co. is installing a 50-hp. boiler at the Mangante mine, near Jamestown.—— It is reported that the Santa Ysabel mine near Jamestown will be reopened and worked again by the Santa Ysabel Mining Co. R. C. Hayward is president of the company.

Tuolumne, April 16.

COLORADO.

CLEAR CREEK COUNTY

(Special Correspondence).—The Homestake adit in the Georgetown district intersected the Golden Jack vein this week opening a body of smelting ore three feet wide.—— Work is to be put under way in the construction of a 50-ton mill at the Centennial mine during the present month.—— A body of ore 14 in. wide was cut last week on the sixth level of the Dunderberg mine.——The Lucania tunnel on lower Fall river, is to be driven an additional 500 ft. The bore is now in a distance of 4500 ft. John McCall is manager.——The Lombard mill at Alice is to be remodeled and the capacity increased at once as the output from the mine promises to be double what it has been in the past. H. I. Seemann is manager.——A body of lead ore two feet wide has been uncovered in the bottom of the 135-ft. shaft sunk on the Park vein of the Highlander Mining & Milling Co. Ira Pollard is manager.

Idaho Springs, April 16.

GILPIN COUNTY.

(Special Correspondence).—Work is to be resumed upon the property of the Euclid Gold Mining Co. in the Pine Creek district.——A local pool of business men has secured a lease upon the Star of the West mine in Russell district. A drift is to be run to cut under the upper workings from which a production of $60,000 was made a few years ago. ——The Foot & Semmons property adjoining the Next President group of claims has been taken over by the Great Bonanza Gold Mining Co. Ltd. of London. Cecil C. Morgan is manager.——Work in the construction of the new mill for the Gilpin-Eureka Mining Co. has been put under way. Two carloads of lumber arrived at the Black Hawk depot last week.——A gold retort weighing 79 oz. was sold last week by the operators of the Egyptian mine on Quartz hill. This represented a clean-up from the Fifty mill and the sum of $1200 was realized.

Central City, April 15.

LAKE COUNTY

After two years of constant work ore has been opened in the Huston adit in the Leadville district. At one portion of the vein the ore is a sulphide of lead and silver with considerable gold, while deeper the ore is oxidized with its main value in gold. The shoot is narrow, but assays from $40 to $100 per ton. Harry Mamlock has resumed operations on the Doris claim adjoining the Huston.——Operations are to be resumed at the Helena mine about May 1.——A lease has been obtained on the First National claim in Iowa gulch by local operators and development work started.——Two shifts per day are now being worked at the Lanphier lease on the Penn property, and 200 tons of

ore per day shipped to the smelter.——Supplies have been hauled to the Theodolite group in Half Moon gulch, and work started for the season.——The Dinero shipped 350 tons of ore during March, and at the present rate of production, the April output will exceed this.

SAN MIGUEL COUNTY

Last year the washout on the railroad prevented the Junta Mining Co. from completing its plant in the Placerville district before the snow became too deep to run the mill. It has now been finished and the test runs have been so successful that the management is now considering increasing the capacity to handle 100 tons of ore per day. ——At Ophir the Crown Point has been taken over by lessees and is being operated after an idleness of eight years. The vein is about 8 in. wide, and averaged 180 oz. per ton where it was stoped. In the same camp the stamps at the Fairview are dropping on good ore from the mine, the Carbonero is shipping, while the Alta and Butterfly are both opening fair ore.

SUMMIT COUNTY

The machinery for the O'Reilly property, in the Breckenridge district, is being forwarded to the mine and the management expects to have the machine-drill at work in the adit within the next two weeks.——The dredge, operating in French gulch, was cleaned up for the first time this season a few days ago and the amount of bullion reported as satisfactory.——Dredge No. 2 on the Swan river has been thoroughly overhauled and is running steadily.——A station is being cut in the adit on the mill-level at the Wellington, and a shaft will be sunk and the lower portion of the vein opened.——At Moctezuma the Ohio-Toledo adit is now in over 2200 ft., and a new vein has been opened. The vein appears to contain good ore and drifts have been started to cut the shoot. The mill is to be equipped with new machinery the coming summer.——There are 38 men now working in the King Solomon mine, at Frisco, where a shoot was recently opened on the No. 11 vein. A drift has been driven 60 ft. along the vein which now contains a fair amount of gold in addition to its lead.

TELLER COUNTY

Sub-lessees operating on the first level on block No. 7 in the Jennie Sample mine, in the Cripple Creek district, opened a body of high-grade ore assaying about $100 per ton. The ore is considerably oxidized and with a small amount of sorting will be shipped directly to the smelter. ——A prospecting permit with an option of a lease on the Ocean Wave property on Battle mountain has been secured by S. W. Vidler who represents Denver capitalists.——The Work Mining & Milling Co. has issued a report for the year ended April 1 stating that there were seven sets of lessees and sub-lessees working in the mine and that $43,127 worth of bullion was taken from the ore produced by these operators. Of this $22,651 was paid to the lessees, $13,280 for milling and transportation, salaries of officers and taxes, $7400, and $11,717 spent in litigation. The surplus on hand at the beginning of the month amounted to $53,641.—— Twelve sets of lessees operating on the property of the Free Coinage Gold Mining Co. are shipping about 40 cars of ore per month. The Altman Leasing Co. is cross-cutting on the 800-ft. level and expects to open the Wilson vein within the next few days.——The Uintah Leasing Co., operating a lease on the Necessity fraction through the main shaft of the Ajax property, is opening a rich orebody and shipping high-grade ore. The company paid its first dividend the first of this month.——The holdings of the Midget Gold Mining Co. have been sold to the Midget-Bonanza Mines Co. for $150,000 which will be distributed as a final dividend to the stockholders.

IDAHO

BOISE COUNTY

The Gold Hill & Iowa Mines Co. is sinking the Pioneer shaft from the 400 to the 500-ft. level. The new 100-ton mill is practically completed and will be in operation in a few days. The method of treatment is a departure from the ordinary practice of the district, so results are being watched with interest. The ore is coarse crushed in the batteries, classified, re-crushed in a 10-ft. Lane mill, the entire product being amalgamated here, and sized with a Richards classifier. It is then concentrated on Bartlett tables and Frue vanners, the sand allowed to go to waste and the concentrate treated in Pachuca tanks. E. E. Carter is manager, and W. L. Bowron, superintendent.

IDAHO COUNTY

The citizens of Elk City have subscribed to a fund to construct a trail from Elk City to the new townsite of Golden where rich ore on the Harmon & Morrow claims started a stampede to the district. There are now several hundred prospectors near the camp, and good showings are reported on a number of claims. J. T. Omo, who holds a bond on a three-quarters interest in the South Fork mine for $112,500, is to incorporate the South Fork Mining Co. to more completely develop the group.

OWYHEE COUNTY

The final payment of $19,250 on the group in the Silver City district which the Silver City Mining & Milling Co. has been operating under bond from Abel A. Berg has been made. The company has been re-financed and the name changed to the Silver City Mining & Milling Co. London 1910.——The Wennersten group has been taken over by an English company and will be more actively worked in the near future.

NEVADA

ELKO COUNTY

(Special Correspondence).—Contact district, situated in the northern part of this county, is about 40 miles east from Jarbidge and 70 miles south of Twin Falls, Idaho; a stage runs three times a week from Rogerson, Idaho, to Contact. Travelers go in, also, from Wells, Nevada. The veins of copper ore in that district, which are claimed to be on the contact of limestone and granite, are being opened on one property by the United States Smelting, Refining & Mining Co. Other properties have been partly developed. Specimens of ore from the camp run high in copper, accompanied by some gold and silver.

Twin Falls, April 16.

ESMERALDA COUNTY

The Goldfield Consolidated has laid a temporary track over the ore-bins and now has 80 of the stamps in the mill dropping. The consulting engineer, J. H. Mackenzie, is at the mine and is devoting all his time to the reconstruction of the plant. Underground a large force of men that has been working in the stopes has been started on development so that the company will have a greater supply of ore blocked out ahead of the stamps than anticipated. The debris has been cleared away from the refinery and three shifts are at work repairing the refinery and building a new conveyor. Officials of the company have given out the statement that the regular quarterly dividend will be declared. ——The shaft of the Grizzly Bear lease is now down 1175 ft. which makes it the deepest in the district. A number of rich stringers have been cut since the shaft passed the 1000-ft. mark but it is not expected to open the main orebody till below the 1200-ft. level.——At the Goldfield Annex lease on the Polverde claim of the Jumbo Extension a stope 70 ft. in length with a 6-ft. face has been started on the intermediate level 40 ft. above the 800 and a carload averaging 25 tons of ore per day is being shipped from this portion of the workings.——Ore is being saved for shipment on the Booth and it is understood that the property will enter the ranks of the regular shippers. On the Webber-McLaughlin lease ore that assays between $30 and $40 per ton is being broken from a 5-ft. face.

LANDER COUNTY

Kimberly still maintains its place among the recent booms and is rapidly developing into a large camp. M. C. Scully has taken up his options on the Hilltop and Independence claims and incorporated the Kimberly Consolidated Mining Co. to develop the groups which total 17 claims. A double-compartment shaft will be sunk to a depth of 500 ft. and 60 stamps added to the mill where 20 heads are now in operation.

LINCOLN COUNTY

W. D. Shemwell, manager of the Elkton, Josephine, and Campbird companies operating in the Chief district between Pioche and Caliente, is to install a hoist at the shaft on the Elkton and further develop the vein that was opened at a depth of 100 ft. In the bottom of the shaft the vein was four feet wide and assayed about $50 per ton in lead, silver, and gold.——Plans are being drawn for a 100-ton mill and cyanide plant to be erected at the Gold Prince property. The company has been developing the property for some time and now has a large amount of ore blocked out.——New machinery is to be added to the equipment at the Pioche X-Ray and operations resumed on a larger scale as soon as the repairs to the railroad are completed.—— George T. Banovich and Robert Corkish who are operating a lease on the Delamar-April Fool mine at Delamar have opened a shoot assaying as high as $1200 per ton and are figuring on building a small mill.——A number of local men have tried to obtain leases on the Jumbo Extension claim of the Delamar company as a 28-ft. vein assaying $8 per ton was opened by former operators of the property. It is reported that the company is to be reorganized in June when the term of the receiver who has been handling the affairs of the company is ended.

LYON COUNTY

(Special Correspondence).—The Nevada-Douglas Copper Co. has entered into a contract with the Mason Valley Co., which is to erect a smelting plant at Wabuska, whereby the former is to ship to the latter's smelter 250,000 tons of ore, at the rate of 10,000 tons per month, beginning with the blowing in of the furnaces, which will be about January 1911. A. J. Orem & Co., who control the Nevada-Douglas, estimate that there are 600,000 tons of ore blocked out in the Ludwig and other mines of the group. In the meantime the railroad now in operation from Wabuska to Yerington and Mason, is to be completed to the Nevada-Douglas mine, in Smith valley, by the time the smelting plant is ready.

Mason, April 18.

The Nevada Mining, Reduction & Power Co. operating at Dayton and Silver City is making good progress in the development of its properties and will soon be ready to start operations on a large scale. The new 40-stamp mill constructed by the Risdon Iron Works of San Francisco will be one of the most complete in the State. The company contemplates building a spur-track from the property to the Southern Pacific near Dayton.

NYE COUNTY

(Special Correspondence).—The District Court at Tonopah has decided the boundary dispute affecting the Indiana holdings and Gold Hills estate of the Pioneer Consolidated company. The terms of the decision are generally favorable to the latter.——The Black Warrior group near Oak Springs has been taken over by W. D. Bobin, A. E. Keables, and George R. Raymond of Salt Lake City. The property has been developed to a vertical depth of 260 ft. by means of an adit and cross-cuts. The ore assays 7% copper and $2 gold, with some silver.——It is officially announced that operations will be immediately resumed at the Grand Central group, in the Horn Silver district. The 135-ft. shaft will be carried to the 400-ft. point and a gasoline hoist installed. Two shoots of ore are exposed near the bottom of the shaft. ——The Nevada Crane recently made a 10-ton shipment to the Western Ore Purchasing Co.——The Great Western has been arranging for the shipping of ore, but has been restrained by an order from Judge Stevens from extracting or milling ore. S. H. Brady recently brought a suit against the company, hence the injunction.

Tonopah, April 15.

STOREY COUNTY

The hoist for the Monte Cristo operated by the Butters company has been taken to the mine and will be in operation by May 1. The company will soon begin shipping ore over the tram from the Chollar and Potosi leases to the mill.——Joseph Deitrich operating a lease on the Best & Belcher croppings has opened good ore and is now shipping material that assays from $20 to $100 gold and $12 to $60 silver per ton. This ground has never been prospected before as it has been regarded as off the line of the bonanzas.——The south drift from the cross-cut on the 2300-ft. level of the Ophir has broken into a 3-ft. shoot of milling ore. Twenty-one cars assaying $23 per ton have been taken out.——In the Consolidated Virginia the raise in the 1750-ft. level is now up 51 ft. in ore assaying a little over $6 per ton.

WHITE PINE COUNTY

New pumps have been installed at the Clipper shaft of the Ely Central mine in the Ely district and sinking resumed. The company was forced to stop operations in the shaft about a month ago on account of striking a heavy flow of water. The Eureka three-compartment shaft has been retimbered and operations resumed.——The adit at the Ely Centennial is now in 580 ft. and is cutting a dolomite formation with considerable native copper and malachite. One shift per day is being worked in the adit, but as soon as a new blower can be installed another shift will be started.——A preliminary survey for a railroad from the properties of the Nevada United Mines Co. at Ward to connect with the Nevada Northern railroad at Ely has been completed. The road will be 14 miles long, standard gauge, and have an average grade of one per cent. When completed the mines at Ward will be in a position to ship 300 tons of ore per day and the saving will amount approximately to $3 per ton.——Charles Minnoletti who has been working the Cornell mine at Hamilton is preparing to ship the ore to the Salt Lake smelters by way of Ely. Considerable ore has been taken from the upper workings though the mine has been idle for some time.——The Steptoe Valley Mining & Smelting Co. has installed an elaborate sampling plant in the concentrator and in the future all tailing from the mill will be sampled and re-treated if it contains too high a value.

NEW MEXICO

OTERO COUNTY

The machinery for the 100-ton concentrating mill of the Tularosa Copper Co. has arrived and is being installed. The properties of this company are near Bent, 12 miles north of Tularosa, on the El Paso & Southwestern railroad. The property is well explored by drill-holes and shafts proving the deposits to be 45 ft. thick, in blanket form, and within 10 to 30 ft. of the surface. The average is 2.6% copper occurring as chalcocite disseminated through the mass. The property consists of 307 acres of patented ground, 15 mining claims, a farm, ranch, and mill-site, and water rights capable of developing 200 hp. H. Vincent Wallace is the consulting engineer. The company has run 7000 tons of ore through its 30-ton experimental mill, producing in concentrate and sorted ore, net smelter returns of $37,381.

PHILIPPINE ISLANDS

J. C. McCoy, of New York, who controls the Colorado mine in the Masbate district has ordered a 20-stamp mill for the property, and the preparatory work is now under way. In the mine development work is being advanced rapidly and a large amount of ore blocked out.——The Benguet Consolidated is considering replacing its 10-stamp mill with a 20 or 30-stamp plant and treating the custom ore of the district. Such a mill or consolidation of the claims would be a great advantage to that portion of the country, and bring a number of claims to the productive stage that are now lying idle.——A new Huntington mill has been forwarded to the Paracale company from Manila.

SOUTH DAKOTA

LAWRENCE COUNTY

The nailing down of the bell-rope in the shaft at the Homestake mine at Lead and the filling of one of the Little Jap drills with dynamite is blamed on the Western Federation of Miners by the officers of the company. Both were discovered before any serious accident resulted.

UTAH

BEAVER COUNTY

The shaft at the Red Warrior mine near Milford is now

being sunk to the 500-ft. level and the management expects to complete the work about June 1. Between the 300 and 400-ft. levels the ore was 50 ft. wide and a winze sunk 25 ft. from the 400 was in ore the entire distance. W. J. Merritt is manager.——The cross-cut on the 100-ft. level of the Moscow mine opened a body of silver-lead carbonate ore.——The drift on the 500-ft. level of the Cedar-Talisman opened the shoot 180 ft. north of the shaft. The ore is the same silver-lead type that the company has been working on the 400 and a raise will be started from the 500 to connect with that level.

JUAB COUNTY

The drift on the 500-ft. level of the Iron Blossom mine in the Tintic district recently broke into a shoot of gold-

Map of Utah.

silver ore and a shipment of several cars assayed $30 per ton. On the 600-ft. level the company has opened three feet of ore that contains 30 oz. silver per ton and from 10 to 15% copper.

WASHINGTON

FERRY COUNTY

(Special Correspondence).—The Republic Mines Corporation has paid the second installment of $12,250 on its lease and option on the Pearl Consolidated group near Republic, which, with royalty added, has put over $25,000 in the Pearl Consolidated Mining Co.'s treasury. The latter has paid its second dividend, amounting to 1c. per share.——The lessees of the Insurgent mine are employing eight men and have shipped 70 tons of ore which assayed $42 per ton.——A carload of machinery for the concentrator at the Kettle River mine, near Rockcut, has been received.——The sub-lessees of the Tom Thumb mine, in Republic camp, have shipped ten carloads of ore, valued at $18 per ton.

Republic, April 16.

OKANOGAN COUNTY

(Special Correspondence).—The Alaska River Red Mining Co. has commenced the season's run on its placers, on the Similkameen river. Several cofferdams will be installed in addition to the one successfully operated last summer.——The Golden Sands company, operating several claims on the Similkameen river, near Oroville, installed a 100-hp. motor and pump last summer and is now getting ready for this season's run.

Oroville, April 16.

STEVENS COUNTY

(Special Correspondence).—The Copper Butte mine in the Orient district has been drained of water, preparatory to resuming work in the shaft. The property is equipped with a gasoline hoist, compressor, and machine-drills.——A new sinking contract has been let at the Summit mine.——The Mars Hill Mining Co. has ordered a steam-hoist, compressor, and machine-drills. The winze is down 45 ft. below the adit and has a total depth of 145 ft. It is on a good quality of ore, containing gold, silver, copper, and lead. Sinking will be continued for 100 ft. when a station pump will be installed, and the winze will probably be sunk to the 500-ft. level.——The Mogul Mining Co. has been organized to operate a group of claims situated five miles north of Orient. The incorporators are Chas. H. and E. W. Scothorn and D. E. Twitchel, of Spokane, and William Brandenberg of Orient.——The Scotia mine has been sold and will be operated on a larger scale.——The Utopia Mining Co. has been organized by the Spencer brothers of Orient, and Seattle capitalists to operate the Jumbo mine, seven miles east of Kettle river.——Work has been resumed on the Blue Grass mine.——A contract has been let for the construction of a 3100-ft. aerial tram from the Globe mine to a railway siding to be put in at the mouth of Boulder creek, 2½ miles south of Orient.

Orient, April 18.

CANADA

BRITISH COLUMBIA

A body ore assaying 55% lead and 200 oz. silver per ton has been opened in the No. 6 adit of the Slocan Star Mining Co. at Sandon. A small seam of gray copper assaying 600 oz. silver per ton has also been opened.——Ten men are working at the Stewart mine on Portland canal and the main adit is now in 275 ft. with drifts started on veins No. 1, 2, and 4.——On the Portland-Wonder property a shaft is down 40 ft. to the vein and drifts started on the ore.——A contract has been let to drive a 75-ft. adit on the Silver Queen property at Copper City. It is thought that this will open the ore at a depth of 100 ft.

MEXICO

CHIHUAHUA.

The steel work of the main building of the Palmilla Mining Co.'s mill at Parral is nearly all up and in about a week the steel frame will be finished when the installation of the machinery will be started. The machine shop, a steel frame building, is all done but the roof and the assay office will be finished in a few days.

JALISCO

The Cinco Minas Co. has been organized to operate the Cinco Minas property in the Hostotipaquillo district and will expend $500,000 in the erection of a new plant which will have a capacity of 250 tons per day.——A body of ore assaying 800 oz. silver and $10 gold per ton has been opened by the Boquitas adit at the Tajo mine in the San Sebastian district. A clean-up of $35,000 was made recently from a run on 3000 tons of ore.

SINALOA

Work has been resumed on the extention of the West Coast line of the Southern Pacific to Guadalajara from the point below Mazatlan where building ceased some time ago and contractors with supplies are being hurried to the end of the line.

SONORA

The report of the El Tigre Mining Co. for the year of 1909 states that the company broke 47,130 tons of ore during the year. Of this 37,721 tons were milled producing 2235 tons of concentrate which with 1911 tons of ore that the mill could not handle was shipped to the smelter of the Copper Queen company at Douglas and the American Smelting & Refining plant at El Paso. The milling ore averaged $24.65 and the gross return from the sale of ore and concentrate amounted to $1,087,273. A net profit of $586,597 was reported for the year, a record surpassing any of the previous work by over $200,000. During the year $409,500 was paid in dividends.——Work is to be started at once on the railroad from Port Lobos on the Gulf of California by way of Vaborca to Tucson. It will open a large copper region near the Gulf, and pass through the gold district of Altar.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

JOHN B. FARISH was in San Francisco.

M. B. COOKE of Chicago is in San Francisco.

CHARLES JANIN is at Grass Valley, California.

ERNEST A. HAGGOTT is in Nevada on professtional work.

J. HENRY RICKARD has gone from Lake George, Canada, to Katanga, Central Africa.

F. LYNWOOD GARRISON has returned to Philadelphia by way of Kingman, Arizona.

ELTON W. WALKER is superintendent for the Mass Con. Mining Co., at Mass City, Michigan.

L. A. WOMBLE is general manager for the Princess Estate & G. M. Co. Ltd., at Roodepoort, Transvaal.

P. R. WHITMAN has left Pachucha on account of illness and is temporarily at Long Beach, California.

MASUTOMO MAYEKAWA of Tokyo, Japan, is in San Francisco and has been visiting the dredging fields.

PAUL L. PAINE has resigned the position of special agent in the Land Office to engage in private practice.

J. B. FLEMING has gone to Goldfield, Nevada, to superintend repairs on the mill of the Goldfield Con. M. Company.

C. M. EYE has resigned as manager for the Benguet Con. M. Co. to take charge of the Colorado mine at Masbate, Philippine Islands.

HORACE F. EVANS, who has been ill at Portland, Oregon, has recovered and gone to Oroville, Washington, to supervise drilling for the Detroit-Oroville Exploration Company.

JESSE J. MACDONALD has returned to California after two years' residence in Europe and is preparing to re-enter the professional field with headquarters at Los Angeles, California.

R. H. BURROWS, of Guanajuato, has accepted the position of manager for the mining companies subsidiary to the K. C. M. & O. railway and will make headquarters at Chihuahua.

H. B. BARLING, formerly with the Cia. Metalurgica y Refinadores del Pacifico, has been appointed assistant superintendent and chief engineer for the San Antonio Copper Co., one of the Cole-Ryan organizations operating at San Antonio de la Huerta, Sonora.

PUBLICATIONS RECEIVED.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE COPPER HANDBOOK. A Manual of the Copper Industry of the World. Compiled and published by Horace J. Stevens, Houghton, Michigan. Vol. IX, 1909. Pp. 1628, index. Price $5.

The Handbook for 1909, as frankly stated in the preface, is a reprint of Vol. VIII with appended chapters which cover the operations of companies that have become active since the previous issue, adding some 128 pages and bringing the total of companies described to over 7551. It also contains chapters on the history, chemistry and mineralogy, mining, and metallurgy of copper, together with a glossary of mining terms. It maintains the high standard previously set by the author who, as usual, is absolutely fearless in cataloguing the 'wild cat' companies. It is well printed on thin paper to keep the size reduced to one convenient volume and excellently edited. As a guide to one interested in copper mining, securities, and statistics it is without a peer.

ELEMENTS OF MACHINE DESIGN. By Dexter S. Kimball and John H. Barr. 8vo.; pp. 452; ill.; index. John Wiley & Sons, New York, 1909. Price $3.

This work embodies the best recent American practice, and is excellently adapted for use in the shop and the school. The energy and force-problem are well treated, with diagrams, and the straining action in machine elements is discussed at great length, and with aid of ample illustration. Commendable also is the statement of the general theory of friction. The book is essentially a guide to correct method in design, suitable for those technically trained. It is a distinct addition to the literature on the subject.

MINERAL RESOURCES OF THE UNITED STATES FOR THE CALENDAR YEAR 1908. Parts I and II. 2 Vol. 816 and 899 pages respectively. Washington, D. C., 1909.

The scope of the Mineral Resources has been considerably enlarged through facilities granted in accordance with a change in the sundry civil appropriation act of May 27, 1908. The figures are obtained mostly direct from the producers, and the work of collecting statistics of mineral production has been greatly aided by co-operation with a number of the State Geological Surveys. The Surveys of Alabama, George, Illinois, Iowa, Kentucky, Maryland, North Carolina, and Virginia have lent their support in this manner. The high value and importance of these volumes is so well understood that we need only say the work is better done than ever.

PROCEEDINGS OF THE ILLINOIS FUEL CONFERENCE. State Geol. Surv., (Illinois), Bull 14. Pp. 89. Urbana, 1910.

The full proceedings of this interesting meeting, held at the inauguration of the branch Mine-Rescue Station of the U. S. Geological Survey, are now available. The occasion was unique in that geologists, mine inspectors, coal operators, Federal officials, coal miners, railway presidents, steam users, and retail coal dealers all came together for serious consideration of the problems of the local fuel industry. The good effects of the conference have been many and similar friendly gatherings might well be more general.

DAVIS HANDBOOK OF THE COBALT SILVER DISTRICT. By H. P. Davis. Pp. 108, ill. Canadian Mining Journal, 1910.

This is a directory of the mines and companies operating in Canada's great silver camp. It has in addition interesting chapter, on the geology of the district, on methods of estimating ore reserves, on concentration, smelting, and related topics. The work seems to have been done with unusual care and the book is a valuable addition to existing technical literature.

GEOLOGY AND ORE DEPOSITS OF THE BULLFROG DISTRICT, NEVADA. By F. L. Ransome, W. H. Emmons, and G. H. Garrey, U. S. Geol. Surv., Bull. 407. Pp. 130., ill., index, maps. Washington, 1910.

An excellent description of an important district. The discussion of faulting especially constitute a distinct contribution to science in general.

GEOLOGICAL RECONNAISSANCE OF THE REGION TRAVERSED BY THE NATIONAL TRANSCONTINENTAL RAILWAY BETWEEN LAKE NIPIGON AND CLAY LAKE, ONTARIO. By W. H. Collins. Canada, Department of Mines, Geological Survey Branch, No. 1059. Pp. 67, ill., map. Ottawa, 1909.

PALEONTOLOGY OF THE COALINGA DISTRICT. By Ralph Arnold. U. S. Geol. Surv., Bull. 396. Pp. 125, 30 plates. Washington, 1909.

A technical discussion of the fossils by which are discriminated the formations in a great oilfield.

UNIT COAL AND THE COMPOSITION OF COAL ASH. By S. W. Parr and W. F. Wheeler. Eng. Ex. Station, Univ. Illinois, Bull. 37, Pp. 68. Urbana, 1909.

This is a scholarly contribution to a subject of great scientific and practical importance.

REPORT ON THE COALS OF THE THREE FORKS OF KENTUCKY RIVER. By James M. Hodge. Kentucky Geol. Surv., Advance Sheets. Pp. 286. Submitted, November 1907.

ANNUAL REPORT OF THE INSPECTOR OF MINES OF THE STATE OF KENTUCKY, 1908. By C. J. Norwood. Pp. 164. Lexington, 1910.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

M. K. R., Seattle, Washington: Bitumen.

A. M. S., Flourine, New Mexico: Jasper; the color due to ferrous iron.

C. H., Hackberry, Arizona: Coarse pegmatite consisting of orthoclase and black tourmaline.

E. D., Winnemucca, Nevada: No. 1, diorite; No. 2, labradorite porphyry; No. 3, feldspar; No. 4, porphyrite; No. 5, quartz porphyry; No. 6, epidote and black tourmaline.

DRILL CONTEST

The drilling contest between the Waugh and a drill of another make was held recently at the Vindicator shaft, at Cripple Creek, for a $400 purse, and the speed attained by each was something remarkable; a few years ago it would have been considered impossible. The ground picked out for the contest was what is known on the Vindicator as the black syenite. The drills were in operation within a few minutes of an hour and a half, the Waugh drilling 49 ft. 10½ in., and the other 35 ft. 9½ in. The air-line from which the machine operated was an inch and a half line to within 100 ft. of the drills, then reduced to one inch, and the hoses fed from that, the Waugh running off 75 ft. of ¾-in. hose, and the other off 50 ft. of same sized hose. The Waugh used was the regular 8-C. The Waugh weighed 62 lb., and the other 78 lb. Notwithstanding the weight and the small air connections of the Waugh it has never been beaten in a drilling contest in the district.

CATALOGUES RECEIVED

The Jeffrey Mfg. Co., Columbus, Ohio. Bulletin No. 39 Roll Crushers. Illustrated. 6 by 9 inches. 16 pages.

Denver Fire Clay Co., Denver, Colorado. 1910 catalogue of assayers' and chemists' supplies, and scientific apparatus.

Hendrie & Bolthoff Mfg. & Supply Co., Denver, Colorado. 'Vulcan Steel Frame Electric Hoists'. Illustrated. 9 by 6 inches. 16 pages.

Power & Mining Machinery Co., Milwaukee, Wisconsin. Catalogue No. 4. 'Rock Crushing Machinery'. Illustrated. 6 by 9 inches. 68 pages.

Morris Machine Works, Baldwinsville, New York. 1910 Catalogue. 'Centrifugal Pumping Machinery'. Illustrated. 9 by 6 inches. 96 pages.

The Economic Machinery Co., Denver, Colorado. 'The Deitz Airolectric Rock Drill'. A concise description of this electrically operated air-drill. Illustrated in colors. 6¾ by 9 inches. 20 pages.

COMMERCIAL PARAGRAPHS

T. H. Proske, of Denver, Colorado, recently shipped a 15-ft. D 24 Ajax drill sharpener to the Degnon Contracting Co., at Forest Glen, New York.

The Wisconsin Engine Co., Corliss, Wisconsin, advises that Benjamin K. Hugh has been appointed as its sales manager in the New England States. He will have offices in the Oliver building, Boston, Massachusetts.

The Arendroth & Root Mfg. Co. announces that the B. M. Osbun Co., with offices in the Commercial Bank building, Chicago, has been appointed its representatives for the sale of Root spiral riveted pipe and Root water-tube boilers.

The Robins Conveying Belt Co. reports extraordinary progress in the way of new business within the last few months. Thomas Robins, president, states that the company has done as much business in the last three months as it did during the entire year of 1909. The Robins Conveying Belt Co. makes the well known conveyor, bearing its name.

EDITORIAL.

CARD-TABLES were among the things ordered to equip a mine recently. The purchasing agent thought the company had opened a social betterment department till he noticed the capital C had been used.

NAVIGATION to Nome will soon be open. The Post Office department plans to begin forwarding mail by the all-sea route tomorrow, May 1. The season promises to be a busy one on Seward Peninsula.

RECLAMATION of land which has been dredged for gold seems to be making substantial progress. Mr. J. H. Leggett has grown a remarkable crop of hay on the rock piles around Oroville and is now experimenting with tokay grapes and apricot trees.

PAYMENT of $1,780,000 in dividends at one time is not common. All the more notable is it when such a sum is paid following a disastrous fire and while reconstruction is still under way. As announced in the newspapers, the Goldfield Consolidated Mines Company will today distribute this large sum among its stockholders.

RAILWAY improvement continues despite still reverberating talk of hard times. The Santa Fe directors have appropriated $31,000,000 for improvements and new equipment this year. Of this sum nearly two-thirds is for new work. The company is engaged in laying second track from Chicago to the Coast and will spend $4,000,000 toward that end this year, west of Albuquerque. With such work under way, with two new lines to the Coast just entering the field, and with Mr. James J. Hill predicting next fall the greatest freight congestion the railways have ever faced, it would seem that railway managers at least see plenty of work ahead.

JARBIDGE, Nevada, has been heralded by its friends as a 'second Goldfield', while others have maintained that the riches of the district were a figment of the imagination of those interested in transportation and outfitting. As usual when such wide differences of opinion exist, the truth seems to lie between. On another page we present an account of the district written by Mr. W. A. Scott of our staff, and including the results of sampling by Mr. F. V. Bodfish. Apparently the work so far done amply warrants further expenditure and there is at least a reasonable prospect of developing good bodies of mill-ore. The development of a mining

district, however, requires work; and if Jarbidge is to fulfill the expectations of its friends a good deal of work needs to be done by individuals and partnerships before company promotion is warranted.

THE LEITER coal mine in southern Illinois has been sold to Bell & Zoller of Chicago and is to be re-opened. The mine is best known because of the long contest waged there by Mr. Joseph Leiter, against the United Mine Workers. There were several conflicts and finally the property was enclosed in a stockade and defended by means of searchlights and Gatling guns. It has been worked for some years with non-union men, the most important commercial mine in Illinois which was outside the trade agreements. The coal is of good grade and thickness, but a series of disastrous accidents has resulted in much loss of life and prevented any substantial profit being realized from its operation. It has been a disturbing factor both to the men and other operators, and the change of ownership will make for peace. Mr. Leiter stood for his legal pound of flesh; but in doing so brought hardship on himself and others. A man of great intellectual strength and marked ability, he is dominating to a degree that brooks no opposition. He took advice from no one and naturally made many mistakes. He is a striking example of a powerful human machine failing of high accomplishment by reason of lack of discipline.

Smelter Fume Troubles

Shasta county smelters, as well as the Anaconda, are again in trouble. Complaint is made that large quantities of Nevada ore are now treated and that the resulting smoke is much more injurious. It is understood that the Government is making trouble for the Bully Hill Copper Mining & Smelting Company and that injunction proceedings are threatened. This seems to us entirely unnecessary. The principle of relative worth recognized in the earlier decisions is, we believe, essentially just. The smelters are much more valuable to the community and to the State than the small amount of land that is being injured. Real damage should, of course, be compensated and is as legitimate an expense in smelting as in any other industry, but the greatest good to the greatest number requires that the smelters be not put out of business unless the owners wilfully refuse or neglect to take all practicable steps to minimize damage to the property of others. There has been little allegation, and no satisfactory proof that this has happened. Indeed smelter men have everywhere shown the utmost willingness to adopt any practicable means of relief. At the Mammoth smelter a bag-house is now being built and at Coram the Cottrell process is being installed. The Mountain Copper Company is making sulphuric acid, but this relieves the situation to only a limited extent, since the market for acid is small, and even granting that it would be economically feasible to make acid and waste it, the damage through the streams would doubtless be greater than that resulting from diffusing the gases through the air. The case is one for patience and mutual forbearance rather than for arbitrary closing of works by means of injunction.

Mark Twain

Samuel Langhorne Clemens, who died at Redding, Connecticut, April 21, once, as he himself has told, walked the streets of San Francisco, footsore and weary, lived in cheap lodging-houses, and earned his meals as best he could reporting for local papers. He came here from Virginia City, where he had worked as reporter and later city editor of the *Enterprise*. In his writings he has given one of the most accurate and graphic pictures of the West of fifty years ago. At Virginia City his salary was forty dollars a week, but, as he relates, he seldom drew it, for "New claims were taken up daily, and it was the friendly custom to run straight to newspaper offices, give the reporter forty or fifty 'feet' and get him to go and examine the mine and publish a notice of it. They did not care a fig what you said about the property so you said something. Consequently we generally said a word or two to the effect that the 'indications' were good, or that the ledge was 'six feet wide', or that the rock 'resembled the Comstock' (and so it did—but as a general thing the resemblance was not startling enough to knock you down). Occasionally we patched up and varnished our reputation for discrimination and stern undeviating accuracy, by giving some old abandoned claim a blast that ought to have made its dry bones rattle—and then somebody would seize it and sell it on the fleeting notoriety thus conferred upon it. There was nothing in the shape of a mining claim that was not salable. These were 'flush times' indeed! I thought they were going to last always, but somehow I never was much of a prophet." His account of the million dollars which was just within the grasp of himself and his two partners, of the night spent planning the 'trip to Europe', and the 'brown stone house' to be built in New York, the unusual and yet natural chain of accidents that led to the neglect of the necessary assessment work until too late and so lost him his early fortune—all this is a true picture of the old West and helps to link his name and fame with the great basal industry of the Rocky Mountains and Pacific Coast. We are glad to know that another and more substantial million came to him before he died, for while the public never learned to think of Mark Twain as 'one of the plutes,' he died a wealthy man. It was clean, honest money that he left: a willing tribute paid by a wide circle of readers as part return for the pleasure he gave them. At his death his books were more popular than those of any other author living or dead. Not America alone, but the whole world mourns his death. He was a many sided man; an undoubted genius and a philosopher. His insight was keen and unerring, but it was his gentleness and simplicity that gave him his wide following. Mark Twain wrote for the average man and was widely loved because, like Lincoln, however high Fate carried him, however much wealth, position, and learning came to be his, he remained always in his heart, one of the common people and was unashamed.

BY THE WAY

Apropos of the testimonial dinner to be given tonight in New York to Dr. R. W. Raymond, *The Mining Magazine* says, editorially: The career of Dr. Raymond synchronizes with the growth of mining engineering across the Atlantic and is identified with the development of the mineral wealth of a continent. When he was born in 1840, the mining industry of the United States had made a feeble beginning; when he went to Freiberg in 1860 there was no School of Mines in America; when he served in the Union Army during the four years of the Civil War the discoveries of gold in California and silver in Nevada had created highly productive industries, and when he filled the post of Commissioner of Mining Statistics, from 1868 to 1876, he assumed a leading part in the application of technical science to mineral exploitation. As a lecturer on economic geology and as the editor successively of two mining periodicals he developed the ability as a journalist inherited from his father and used to splendid effect when in 1884 he became Secretary of the American Institute of Mining Engineers. This post he has held uninterruptedly for 26 years, so efficiently, so completely, and so vividly, that the Institute has become identified with his name and personality. He practised as a consulting engineer after he resigned his Federal appointment, and in later years he has acted in an advisory capacity, especially in mining litigation, a department in which he early achieved a unique position as a skillful advocate. Since 1903 he has been lecturer on mining law in Columbia University. Of his other multifarious activities it is not necessary to speak at this time, save to emphasize an exceptional versatility.

It is an open question whether he plays chess better than he plays whist, or writes hymns better than he composes stories for children, whether he is stronger as superintendent of a Sunday school or as leader in the intellectual jiu-jitsu of a mining lawsuit, whether he preaches in Beecher's pulpit better than he lectures at Columbia, whether he talks more convincingly than he writes, and finally whether he is a great mining engineer or only a great man. Undoubtedly Raymond's work as editor of the *Transactions* of the American Institute is his greatest service to the mining industry. Here he has proved himself incomparably able and stimulating. Many of the best writings on technical science have been prepared on his initiative and at his suggestion. For more than twenty years the *Transactions* have been enriched and concentrated by the labor of his pen until the successive volumes constitute a magnificent reference library of well digested technical information. If he had done nothing more, the *Transactions* would be achievement enough. And he has done so much more. As a friend of R. P. Rothwell he collaborated on *The Engineering and Mining Journal* for many years, and there is hardly a technical periodical of the first class that has not been enriched with the products of his pen.

Of course, he is, and has always been, the life and soul of the Institute meetings. Presidents can come and go, but the Secretary remains. It would be invidious to compare the easy grace and confident skill of the Secretary, as a speaker, with the clumsy but well meant efforts of those who have filled the honorable office of the presidency, but such comparisons have been inevitable. At times the revolution of the Institute around its Secretary has proved embarrassing even to the Doctor. From such embarrassment he extricates himself readily. The present writer remembers how at Aspen, in 1896, it was suggested that someone should tender the thanks of the visiting members to the local committee and to local citizens for facilities and hospitalities provided. As the president and other members were successively invited to discharge the graceful task, each said: "Oh! No, better ask Raymond to do it." Finally the Doctor rose, prefacing his remarks with an apology for seeming reluctant to perform an obvious courtesy, and explaining his position by reference to the story of a boy whose father had served in the Civil War and had talked so much about his own doings in the campaign that the small boy finally put the question: "Pop, was there anyone else in that war?" Most of us thought that if there were 'others', they failed to make themselves numerous. And at Chicago, in 1893, on the occasion of an International Science Congress, the leaders of thought on various subjects had spoken, in French, in German, in broken English, without igniting a spark of sympathy or illuminating a line of thought. Then rose our Secretary. He did not begin with the conventional "Ladies and Gentlemen"; he startled his audience by addressing them in his Plymouth Church style as "Brethren." Then, referring to the purpose of such an international gathering, he said that we had come there in the hope perhaps of lighting on something new, some invention or theory, or of discovering a fresh technical method, but we had done better: we had "discovered one another." There he expressed the one salient feature of such a meeting of scientific men from every part of the world. It was the one great fact made evident amid a multiplicity of speech-making, and it was stated by Raymond in words that I have only feebly outlined. This happy faculty for expressing clearly the inchoate ideas of a large meeting is the mark of the born orator. His is "the brightness of carved speech."

Another less cheerful characteristic is a fondness for writing obituaries. The obituaries that Raymond writes are more inspiring than the presidential addresses of most men; like the burial service of the Church of England, they are meant not so much to honor the dead as to inspire the living. They do. We confess to having read all of them, as they have appeared, and finding in them sound philosophy, deep religious feeling, and highly stimulating thought.

But this is no panegyric; it is simply a greeting from those of us who would like to be at the 70th birthday dinner and are prevented from participating in that delightful celebration. For ourselves, for the members of the Institute in distant lands, for the profession in general, we venture to express to Rossiter W. Raymond an affectionate regard that is and always will be

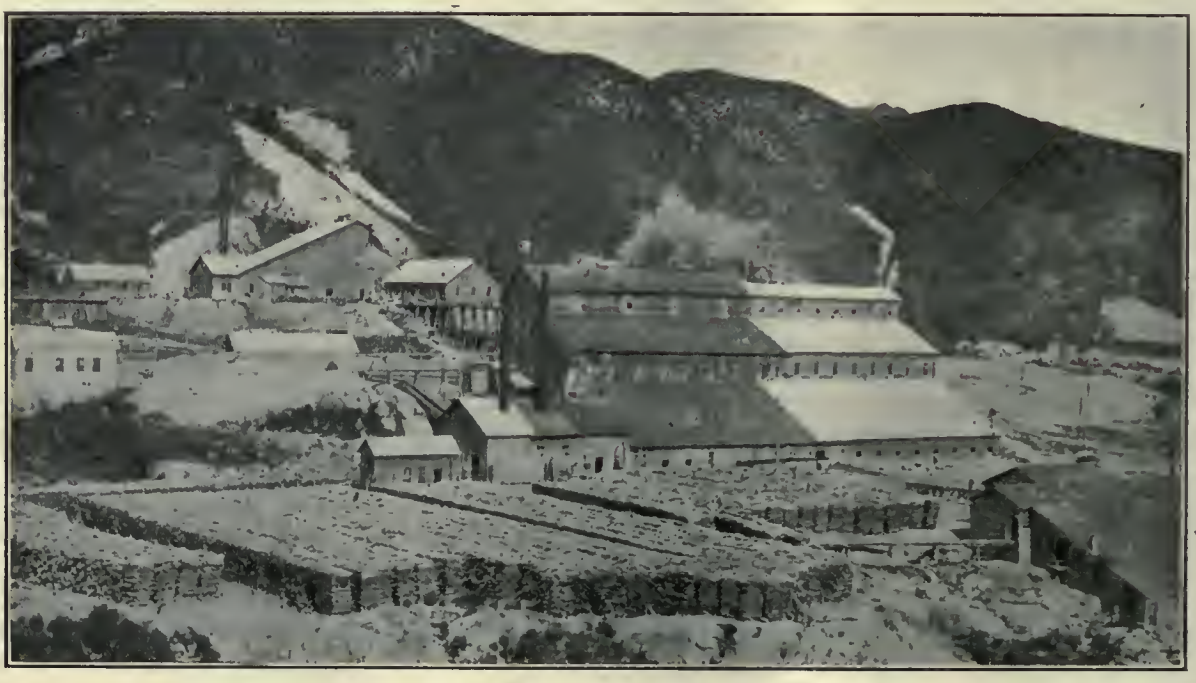
"Above the mere fortuities of place
And cold interposition of the sea."

Costs at Unsan, Korea

Written for the MINING AND SCIENTIFIC PRESS
By A. E. DRUCKER

Year by year the Oriental Consolidated Mining Co. has been gradually reducing its costs so that at present any ore that assays more than $2.75 per ton can be handled at a profit. Great credit is due H. F. Meserve, who, for the past twelve years or more, has been general manager. In a country far from technical assistance and skilled labor he has developed a property and an organization that has produced excellent economic results for the shareholders, and at the same time has instructed and greatly benefited the Korean people.

Up to June 30, 1909, the company has produced 1,934,008 tons of ore containing $12,417,260. The last annual report, for 1909, gives the total ore treated at 293,417 tons valued at $1,716,104 ($5.79 per ton). The net total yield in bullion equaled $1,421,213 or an extraction of 82.8% of which 51.8% was saved by plate amalgamation and 31 by cyanidation of concentrate. The net profit for fiscal year 1909 was $556,369. Detailed costs are given in the following tables:



Tarboie Mill, Oriental Consolidated Mining Company.

MINING AND DEVELOPMENT COSTS *

	Quantity.	Cost.	Cost per ton.

*Concentrate treated 34,152 tons.

SUMMARY OF COSTS

	Cost.	Cost per ton.
Mining and development	$467,356.33	$1.590
Milling	171,541.68	0.580
Ore transportation	4,707.49	0.015
Cyaniding concentrate	47,648.80	0.165
General expenses	108,952.13	0.370
Total	$800,206.43	$2.720

The total cost of $2.72 per ton compares favorably with Treadwell and Homestake, and is considerably lower than the cost at Kolar, Waihi, Kalgoorlie, or on the Rand. While labor in Korea is efficient and cheap, on the other hand the cost of power is comparatively high. Supplies are more expensive than in most places on account of the mines being some 7000 to 10,000 miles from the base of supply. Recently there has been a change in management at the mines, Alfred Welhaven having succeeded H. F. Meserve who becomes managing director with headquarters in New York. Mr. Welhaven is well equipped with a long mining experience in Korea, and under his able direction the good work will no doubt continue.

Old Mexican land measures are confusing. Therefore the following notes by F. W. Johnson, published originally in the *Galveston News* for 1859, and re-published recently in *Engineering-Contracting*, are helpful. From 1821-2 to 1830 there was no uniform measure in laying out lands. Chains used were from 29 ft. to 28 ft. 6 in. and 27 ft. 9⅔ in. Each surveyor regulated his chain by what he believed the colonization laws required; hence the difference in old surveys. In 1830 the two-pole chain of 50 links, reduced to 10 varas of 33⅓ in., making the length 27 ft. 9⅓ in., was established in Austin's colony, every 5 links of which equals 1 vara and every link equals $^{2}/_{10}$ of a vara. The long and land measure established by the Government of Mexico, compared with that of the United States, is found to be less by a discount of 8%. Hence 1 yd. equals 1.08 varas and 100 yd. 108 varas. Hence, also, yards by 1.08 equals varas, and 1.08 times 1.08 equals square varas in terms of yards. There is no measure less simple than the Mexican. The vara is the unit; 5000 varas the side of the league, 1000 varas the side of a labor. The labor being the least subdivision of the league, may be regarded as the unit in quantity, and is the $^{1}/_{25}$ part. An area 25,000,000 square varas equals 1 league or 4428.4 acres. An area of 1,000,000 square varas equals 1 labor or 177.136 acres; 5654.3797 square varas equals 1 acre.

MINING DEBRIS IN CALIFORNIA

In reclaiming the Great Valley of California the removal and control of mining débris in the rivers play an important part. It is estimated that the bed of the Yuba river alone contains 300,000,000 cu. yd. of débris. By these deposits the low-water stage of this stream was raised 15 ft. at Marysville between 1849 and 1881, and the stream bed near this place is now 13 ft. above the level of the surrounding farm land, so that it has been necessary to build large dikes or levees along the river. For four years the United States Geological Survey has been studying this débris problem, as it has been called, and in connection with the study a hydraulic laboratory was built at the University of California, at Berkeley, for the experimental investigation of the laws of transportation of sand and gravel by water. This investigation has outgrown the narrow limits of the laboratory, and it is proposed to continue this work on a much larger scale in connection with one of the projects of the United States Reclamation Service.

In a preliminary report now in preparation the apparatus and methods employed will be described and the results obtained will be expressed by formulas and curves. Relations connecting the discharge, slope, and load will be given for eight sizes of sand and gravel and for artificial and natural mixtures. The experiments included stream transportation, in which the stream bed is sand or gravel —a self-made bed—and flume transportation, in which the bed is wood or metal, as in sluicing.

The accuracy and the applicability of the results to practical problems will be discussed and the data that have only an indirect bearing on the débris problem will be presented in three appendixes. If means are provided for the use of the larger apparatus and the much larger water-supply that will be available in connection with the reclamation project, some of the data thus far obtained will be tested and the relations connecting the factors of transportation will be extended so as to make them more directly applicable to problems of stream control and economic sluicing.

Coal is bought by the United States Government to the value of about $7,000,000 every year for use in the navy, in public buildings in Washington, and other cities, and for other purposes. About one-third of it—mainly coal used in public buildings—is bought on specifications under which prices are fixed according to the value or quality of the coal delivered by the successful bidder. A definite standard of quality for the coal thus purchased is specified by each bidder and this standard is considered in awarding the contract. If the value of the coal furnished is below the standard fixed, a discount is made from the contract price; if its value is above the standard an allowance is made for the excess of value and a proper sum is paid in addition to the contract price. The value is determined by tests and analyses made by the Geological Survey on samples taken from the coal furnished by the contractor.

Pebble-Mill Amalgamation

Written for the MINING AND SCIENTIFIC PRESS
By W. H. HARDINGE

To those who have had trouble in the 'flouring' of quicksilver in their metallurgical work the bare suggestion of putting it in a pebble-mill will be apt to bring forth comments more positive than elegant. Such at least was my mental attitude when the suggestion was made to me of the possibilities of amalgamating in the pebble-mill. We of the older line of metallurgical workers are, perhaps, too prone to 'let well enough alone', and in the letting alone are forced into the background by the more daring younger investigators. This was the case when J. M. Elmer, of Tuolumne, California, tried quicksilver in tube-mills. The experiment was successful and he advanced his recovery from 65 to 85 and even 90%. Mr. Elmer credits A. D. Foote, of the North Star mine, at Grass Valley, California, with the first actual success with this method. Mr. Foote, it appears, met with considerable success in this direction.

From Mr. Elmer's statements it would seem his first work was a success only in so far as heads and tailing showed an appreciable difference. The difference in assay between the tailing before and after the addition of the quicksilver to the feed of his two 8-ft. Hardinge pebble-mills was very marked. After the difference due to mechanical 'saturation', which made itself apparent for two or three days, had been overcome, there was not only an actual recovery in bullion of the difference between heads and tailing, but for a time an additional but fluctuating recovery in some instances of more than the normal amount. This excess recovery can only be accounted for on the supposition that some of the gold previously lost had been retained within the mill. The saturation necessary before recovery begins is naturally proportional to the area of shell of mill and charge of pebbles, and might be prohibitive, if quick results are desired, especially in the old style of cylindrical mill.

At Tuolumne Mr. Elmer is crushing through a four-mesh battery-screen. A short copper plate is interposed between the screen and the pebble-mill and the total product, amounting to upward of about 100 tons in 24 hours from 10 stamps, is then passed directly to an 8-ft. Hardinge mill into which is fed at regular intervals of half an hour, a spoonful of quicksilver; the regulation wooden mustard spoon being used. From the pebble-mill the pulp is run through a box distributer over a second set of amalgamating plates where additional free gold or amalgam produced within the mill is caught. A plan or flow-sheet of the method is shown below.

After passing the second set of plates the pulp is concentrated, about 10% additional being recovered. The concentrate has heretofore been shipped to the smelter for treatment. It is Mr. Elmer's intention to try a still further advance in the treatment of his concentrate by converting one of his two mills into a re-grinder for concentrate and for further inside amalgamation. When this is done, the grinding will be carried to a point of converting the mass into a slime. Under these conditions flouring might be anticipated, but if Mr. Elmer's opinion is correct, the quicksilver is no longer free when it issues from the pebble-mill, having been converted into a gold amalgam. This, owing to its weight and cleanness through scouring in the mill, is easily caught on the outside amalgamating plates.

Considering the high percentage of saving and the simplicity of operation it would seem as though this

Plan of Work at Tuolumne.

method of internal amalgamation might become a strong competitor of the cyanide process; especially in the case of a combination mill where amalgamation and concentration is followed by cyanidation. Mr. Elmer has used native quicksilver fed direct to the pebble-mill. He has also used a soda-amalgam made by mixing a small amount of metallic sodium with his quicksilver. In the case of the soda-amalgam I question whether flouring occurs. The final result would be minute particles of gold-soda-quicksilver-amalgam readily caught on the plates.

At my suggestion the experiment has been made of attaching to the outlet trunnion of the pebble-mill an amalgamated copper cylinder revolving with the mill forming a peripheral plate or cylinder with a speed of about 100 ft. per minute. The pulp flowing through the revolving cylinder is carried with a gentle motion up its side. The gold particles having constantly changing surface exposed, readily amalgamate with the quicksilver on the copper surface just as on an ordinary inclined plate. The experiment showed that the greater portion of the gold was accumulated within a few inches of the outlet of the mill and a very short cylinder, about 18 in. long, did good work. Since, however, in this case outside plates already had been provided, no particular advantage was gained. One advantage of this style of plate would be in the fact that the cylinders can be attached and detached without stopping the mill and are easily removed to a safe place for making the final 'clean-up'.

In the Baltic provinces of Russia peat has been used for some considerable time in the breweries and distilleries, but all attempts to introduce it as a fuel for domestic use have been unsuccessful. This is attributed to the low price of wood, which is cheaper and better adapted to the national stove. Since the year 1906, however, there has been a marked rise in the price of wood, it having reached at one time last year a price more than 50% above that of 1906, and more than double that of 1892. The need of cheaper fuel has now become urgently felt, and attention has been drawn to peat.

Hydraulic Excavation on the Panama Canal

In connection with changes made at the Pacific entrance of the canal, it has become necessary to remove a large amount of alluvial material in the section from La Boca to Miraflores. The *Engineering Record* in its issue of April 2 has presented a full account of the plans for this work. From this the following abstract is published by permission.

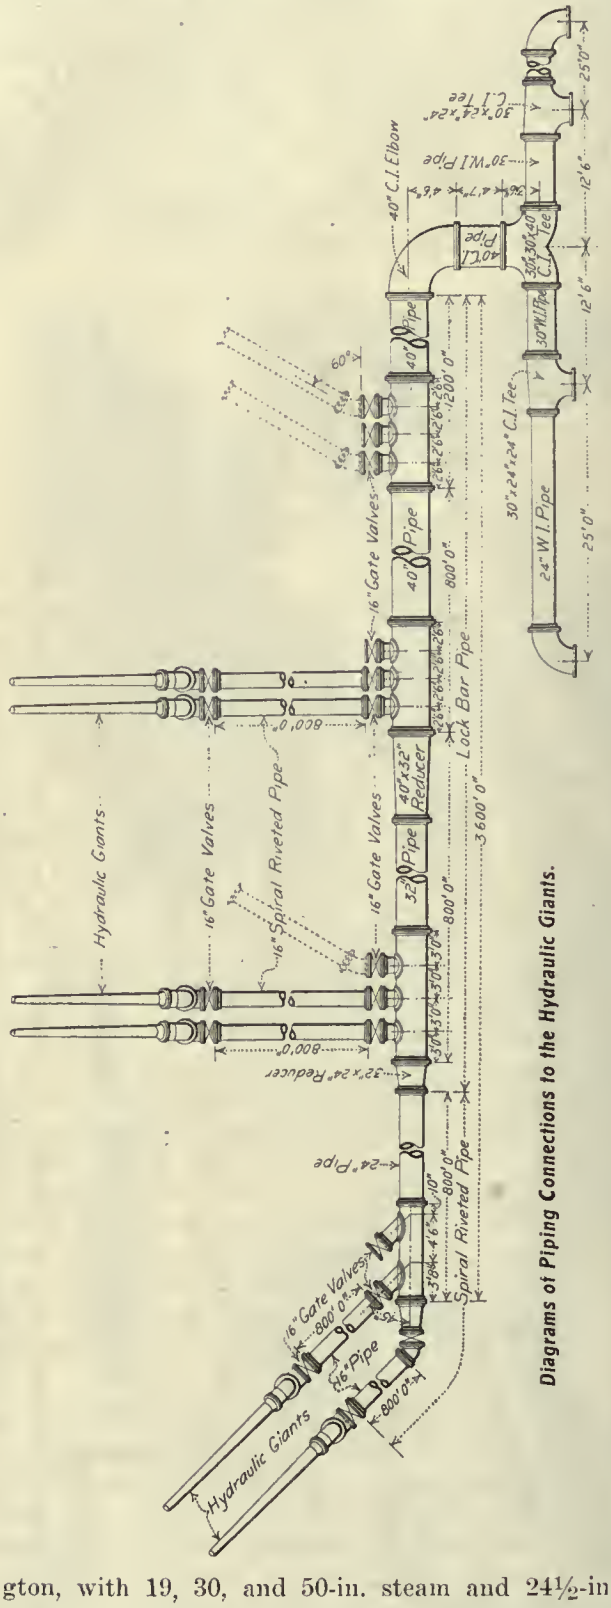
There is estimated to be over 7,800,000 cu. yd. of dark loam, containing about 15% of sand and some gravel, and in order to leave time enough for the excavation of rock below, this alluvial matter would have to be handled in less than 18 months. It is evident that a steam-shovel is too small a unit for this work, as it would take 10 shovels, 25 locomotives, 400 cars, and miles of track, all within an area 9000 ft. long and 500 ft. wide. The use of ladder or dipper dredges, with attending tugs and barges, would do away, to a certain extent, with this crowded condition, as five units would be sufficient. The long haul, the large cost and length of time required to put the plant upon the ground, however, prevented the adoption of this method. Suction dredges would seem, at first glance, to be the proper machinery. They could be used in large units, would eliminate the long haul, as well as the numerous barges and tugs for spoil transportation. In addition, they would give (at $400,000) a lower plant cost than any of the other layouts before mentioned. However, one year's experience has demonstrated the inability of the 20-in. suction dredge 'Sandpiper' to handle to advantage the stiff clay, mixed with sand and coarse gravel, which covers the rock. This method of removal was, therefore, out of the question; and after a thorough investigation of the material to be moved, and the effect of a jet on it, the hydraulic system of excavation was finally adopted.

This system involves two main operations; first, the breaking and disintegrating of the material by a water-jet under high pressure, so that it will flow readily to the sump; second, the lifting and conveying of the dirt-laden water by a dredge pump, through a pipe-line to the dumps. To perform these two operations the following plant is provided: central pumping station, discharge main with branch lines and hydraulic giants, and dredging pumps.

The central pumping station is situated west of the canal, near the bank of the Rio Grande, and near the middle of the section to be excavated hydraulically. The house, a light frame building, covered with tarred paper, is divided by a partition

Area on the Pacific Division of the Panama Canal to be Excavated by Hydraulic Monitors.

into an engine room of 50 by 100 ft. on the east side, and a boiler-room 40 by 100 ft. on the west; the floor being at El. + 12. The purpose of this station is to furnish water at a pressure of 150 lb. and this will be done by four horizontal direct-acting triple expansion pumping engines, built by Henry R. Worthington, with 19, 30, and 50-in. steam and 24½-in. water cylinders, and a 24-in. stroke. The four units are lined up parallel to each other at a distance of 25 ft. from centre to centre, the steam ends facing the boiler-room. Along the east side of the building, and extending to the river, is a trench 20 ft. wide at the bottom, which will serve as a sump. A concrete wall will be carried up to the floor of the engine room, to separate the pump foundation from the sump.



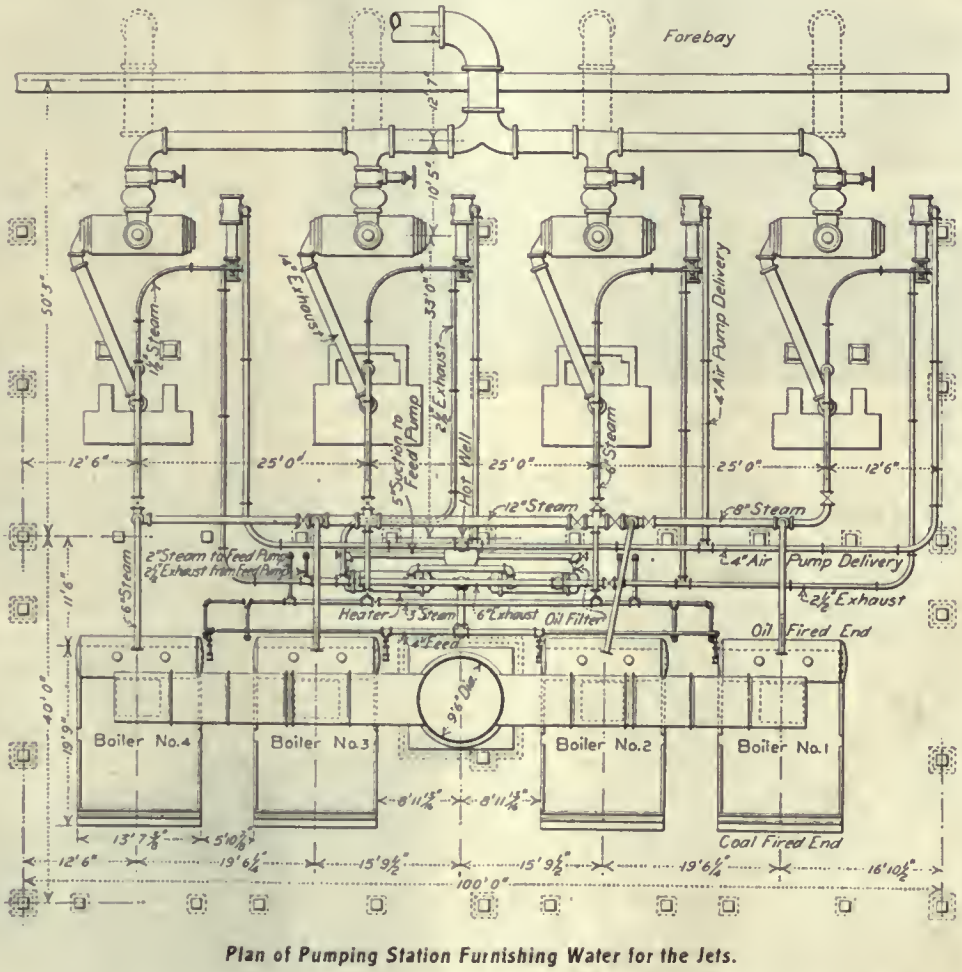
Diagrams of Piping Connections to the Hydraulic Giants.

The 36-in. suction pipes, one for each pump, are made of cast iron, and reach, with their foot valves, 24 in. below the waterline, which is at El. – 10, and connect by a quarter-bend to the pumps. Each engine has its own surface condenser built into the discharge pipe, and an independent direct-acting single cylinder 12 by 20 by 24-in. vacuum pump. At El. + 20, the pumps discharge toward the sump into a common delivery pipe, from which they are separated by a 24-in. check valve and a 24-in. gate valve. The delivery pipe has two branches which begin at the outside with a diameter of 24 in. and increase in size toward the centre line of the building, where they unite in a Y and connect with the 40-in. main. Each unit is guaranteed to furnish 7500 gal. per minute at 150-lb. pressure, with an efficiency of 95 ft.-lb. per British thermal units, corresponding to a coal consumption of about 1500 lb. per hour. In the boiler-room are four Babcock & Wilcox water-tube boilers arranged in two batteries of two each. The boilers are standard, have 4500 sq. ft. of heating surface each, and are designed for a working pressure of 150 lb. per square inch, without superheat. On the side toward the engine room the boilers have oil furnaces; on the other side, fire doors, grates, and ash pits are provided, so that coal can be fired in case of emergency. The boilers have steel casings, arranged with magnesia and tile insulation. The smokestack is steel and situated between the batteries, to which it is connected by a steel breeching. The stack is 9 ft. 6 in. inside diameter, 150 ft. high, and is guyed by three sets of four wire ropes. An automatic stop and check valve and a stop valve are provided in the 6-in. lead from each boiler to the 12-in. steam header, and a stop valve at the 6-in. outlet of this header to each pumping engine. Two 10 by 6 by 10-in. brass-fitted boiler feed pumps of the centre packed plunger pattern, two 1000-hp. Goubert feed-water heaters, with Ross oilfilter and a hotwell, are situated in front of the boilers, where they can be controlled.

Fuel oil is stored in two steel tanks having a capacity of 2000 bbl. each. These tanks are situated on the hill-side behind the station, and are connected with the main line of the Union Oil Co. of California, which supplies the Canal Commission with fuel oil. The oil is fed by gravity to the boilers, through a 4-in. pipe and reaches the burner at 50-lb. pressure. Steam for atomizing the oil is supplied at full boiler pressure.

The discharge main has a total length of 3600 ft., and is made up of 2000 ft. of 40-in. lock-bar pipe; 800 ft. of 32-in. lock-bar pipe, and 800 ft. of 24-in. spiral riveted steel pipe. The plates used for the different sections are No. 6, 8, and 10 U. S. standard gauge, respectively. The lock-bar pipe is made by the East Jersey Pipe Co., in lengths of 30 ft., which are to be connected by forged steel flanges ¾ in. thick. Five air-valves are mounted at equal distances to prevent rupture of the pipe in case of sudden discharge and to allow the escape of air while the pipe is being filled. Twelve openings, in groups of three, fitted with 16-in. gate-valves, are so situated in the main as to permit the connection of branch lines, as the progress of the work demands.

At first the main will be in the position shown by heavy lines on the map; but after the portion north of the central station has been excavated, it will be taken up and relaid in the position indicated by broken lines. The main will lie in each of these positions over six months. There will be but two slight curves, and the pipe will lie at an average down grade of 0.3%, beginning at El. + 20. The greater portion of its length will rest upon a berm in the slope of the approach track leading to the central station, thus giving a well graded and drained foundation. Close to the central station, the pipe will rest upon a trestle. Cables fastened to dead-men will oppose the side thrust at the curves and at the points of connection with the side lines.



Plan of Pumping Station Furnishing Water for the Jets.

An asphalt compound will be applied hot, internally and externally, to the pipe to prevent corrosion. From the discharge main to the six hydraulic giants, the pressure water is carried through branch lines formed of 16-in. spiral riveted steel pipes, in lengths of 30 ft., and connected by forged steel flanges. A total of 4800 ft. will be furnished by Abendroth & Root Mfg. Co. of Newburgh, New York.

Two giants, working to supply one dredge-pump, constitute, with that pump, one working unit. To each unit belong three branch pipe-lines. While one of these lines is being shifted, the other two will supply the two giants, thus avoiding loss of time. A number of 30 and 45° elbows are kept in stock, to be used whenever necessary to give flexibility and cause the pipe-line to conform to the ground surface.

The hydraulic giants or monitors are manufactured by the Joshua Hendy Iron Works of San Francisco, and represent the latest type operated successfully in the La Grange mine, Trinity county, California. Each giant weighs 1500 lb. and consists of a base for attachment to a 16-in. gate valve at the terminus of the pipe-line, a horizontal and a vertical joint, and a long conical reducing piece. To decrease the frictional resistance of the horizontal movement, a ball-bearing has been introduced, and a weighted lever is attached to control the direction of the jet. A deflecting nozzle fitted to the discharge butt of the giant permits deflections through a small angle, without changing the position of the main body of the monitor. The taper piece of the giant is fitted on the inner side with two sets of guide vanes, which prevent a scattering or rotary motion of the water after it has issued from the nozzle, and a solid efficient stream is thus insured. Different sizes of nozzles will be used, varying from 4 to 6 in. diameter, according to the nature of the material being worked. Owing to the frequent shifting, the monitor cannot have a heavy or permanent foundation. The base will merely be bolted to a 10 by 10-in. timber 10 ft. long, placed at right angles to the terminal length of the feed-pipe. This timber will be laid in a trench and weighted down in soft material, or secured with dowel pins on bedrock.

Three units of dredging pumps will be in use, each consisting of an 18-in. single-suction dredge-pump, direct connected to a 655-hp. induction motor, resting on a common cast-iron base plate. This unit, with the necessary auxiliaries, will be set up on a barge. The pump, built by Henry R. Worthington,

has a cast-iron steel-lined casing of split pattern. The runner shaft is supported by a single bearing, which, owing to the great overhang, is made especially long. This bearing is designed also to take the horizontal thrust, is supplied with ring oilers, and is entirely separated from the casing, thus eliminating the possibility of foreign matter working into it. The manganese steel impeller is shrouded, has five blades, and is designed to lift, per minute, 10,000 gal. of salt water containing 10% of solid material, against a varying actual head up to 70 ft., while running at 480 r.p.m. The pump, with base plate elbow and valve, weighs 29,600 lb. The cast-iron suction pipe is 12 ft. long and 20 in. diameter. The discharge pipe, a 20-in. spiral riveted pipe, manufactured by the Abendroth & Root Mfg. Co., is 1200 ft. long, and connects with the pump at an angle of 30° above the horizontal. The 30-ft. lengths are flange-connected, and will be supported wherever necessary by light wooden bents that are adjustable to different heights, and easily set up and taken down.

The motor, furnished by the Westinghouse Electric & Manufacturing Co. is of standard design, for three-phase alternating current at 2080 volts and 25 cycles. It weighs 12,800 lb. and is operated at a speed of 480 r.p.m. The machine may be started by pressing a push button. The starter will consist of seven oil immersed switches, which at first connect the motor to reduced starting voltage; then increase the voltage gradually until, with the controller at the last notch, the motor is connected across the line and the auto transformers are disconnected. The acceleration of the motor will be automatic, and controlled by a power-driven master-switch with series relays. The switch-board consists of a single slab of finished slate 22 in. wide, 48 in. high, and 1½ in. thick. On this panel will be mounted an indicating and an integrating watt-meter, a 300-ampere oil circuit breaker, and a pair of time limit relays of the fused type. The electrical apparatus, switchboard, and auto-starter weigh 5000 lb. The priming of the dredge-pump is done by a horizontal 10 by 10-in. single cylinder vacuum pump, of the piston pattern, geared 5 in 1, and driven by belt from a 5-hp. induction motor. This priming outfit weighs 1300 lb. and is built by the Dean Steam Pump Co. For the transmission line connecting the dredge motors with the Miraflores power-house, 2400 ft. of wire-armored three-conductor cable, manufactured by the Kerite Insulated Wire & Cable Co., is used. Each conductor is No. 00 B & S gauge, stranded.

The barges for the dredging units will be built of reinforced concrete, on temporary ways situated near station 2060-50 on the bank of the cut now being dredged. After allowing sufficient time for the setting of the concrete they will be launched, the dredge pump with its motor and accessories erected, and the finished unit towed into position. After the dikes are closed, the discharge-pipes laid, and the motors connected to the power station, the pumps will be started and the water lowered until the pontoon settles almost to the bottom of the cut. Then the barges will be anchored in the lowest places, which will form the sump for the suction-pipe.

The giants will now attack the bank, washing down the material into sluices, which carry the earth-laden water to the sump of the dredging units. From the sump the mixture will be pumped through the discharge-pipe and spread over the low ground selected for that purpose, on both sides of the canal. At first the giants have to be operated so as to lower the dredge-pump until it reaches bedrock. In doing this, the banks will be given the steepest slope that will stand without endangering the dredge. After this preparatory work is finished and the greatest possible head for sluicing obtained, the regular operation of the monitors can begin. The cut will be made in two benches, and the jet, with a pressure of 130 lb. per sq. in. at the nozzle, will be used to under-cut the bank, thus causing much of the material to fall by gravity. The monitors will be placed as low as possible, at a distance of 50 to 150 ft. from the bank, and the jet will be played on the bank at an angle, rather than striking the face of earth squarely. Whenever the dredging units will have to be moved, the monitor will cut a new sump and a channel leading to it, and the water will be allowed to rise high enough to float the barge to its new position.

With the supply main in the first position, the work will begin at the upper end of the cut (at the lower end of the locks) and will gradually progress southward, each unit having assigned a section about 1000 ft. long. The dredged material will be discharged behind dikes and distributed evenly by gradually shifting and lengthening the discharge-pipes. In this way a large tract of land near Corozal will be reclaimed, which is now under water during spring tides, or is so low that the tide-water keeps it saturated. It is the intention to cover these lowlands to El. + 15. As the surface of rock is at − 30, the pumps will have to work against a maximum head of 45 ft., not including friction and velocity heads. About 1,000,000 cu. yd. of the hydraulically excavated material will be deposited by two of the dredge-pumps in the core of the Miraflores dam, whose crest is at El. + 70. To overcome the additional lift, each of these pumps will be assisted by a motor-driven 18-in. relay pump, which is identical with the dredging units. The suction end of the relay pump will be connected to the end of the dredge-pump discharge pipe: the discharge end to a 20-in. spiral riveted steel pipe, of which 1200 ft. is on hand. When used as relay pumps, these units will rest on solid concrete foundations; afterward they can be erected on barges and used as additional dredging pumps.

Phosphate-land withdrawals in force March 4, 1909, covered all vacant public lands in an area comprising 4,493,551 acres in Wyoming, Utah, and Idaho. During the year areas covering 2,389,141 acres were restored to entry, for the field work showed that they contained no phosphate. Additional withdrawals including 399,693 acres have been made and the form of withdrawal has been changed so as to cover entered as well as vacant lands. All unpatented lands in an area of 2,504,103 acres are now affected by phosphate withdrawals.

Jarbidge, Nevada

Written for the MINING AND SCIENTIFIC PRESS
By W. A. SCOTT

The new mining camp of Jarbidge is situated in the northern part of Elko county, Nevada, seven miles south of the Idaho-Nevada State line. It is about 95 miles southwest from Twin Falls, and the same distance from Buhl, in Idaho, these being the nearest railroad supply points on the Idaho side. The distances to the camp from Elko and Deeth, Nevada, are 80 and 65 miles, respectively, the former on the Southern Pacific and the latter on the Western Pacific. The travel to Jarbidge is divided among the railroad points named, though at present most of the passenger and freight traffic appears to be from Twin Falls, which has excellent hotel accommodations. A branch railroad of the Oregon Short Line runs 28 miles southerly from Twin Falls to Rogerson, and the stage trip begins at the latter place, making the distance into Jarbidge 67 miles from the railroad. The stages leave Rogerson at 9 a.m., and arrive at Rim Rock, on Bruneau river, at 6 p.m. Passengers stop here over night, and meals and tent lodgings are provided. The following day the traveler reaches Jack Hole, 12 miles farther, at noon. This is the local name of the canyon formed by the east fork of the Jarbidge river, and which is four miles from the town of Jarbidge. At the time of my trip, Jack Hole was the end of the stage line; the remaining four miles had to be traveled either on foot or horseback, as the route led across the canyon and over a ridge having precipitous slopes. However, a wagon-road was being graded over this part of the route and by the time this is in print stages and wagons will be going into camp, resulting in greatly reducing the freight rate on merchandise.

Rim Rock on Bruneau River, on the Way to Jarbidge, Nevada, From Twin Falls.

Jarbidge is a typical camp of tents with a few log cabins. It is strung along Jarbidge river for a mile, and up Bear creek, which comes into the Jarbidge from the west. The Jarbidge and its tributaries drain the northern slopes of the range of mountains of that name which culminate in Jarbidge peak, reaching an altitude of about 12,000 ft. There are four other conspicuous peaks in this cluster, and travelers approaching from the Idaho side have designated them as the Five Peaks. Their southern slopes drain into the tributaries of the Humboldt river. The Jarbidge river, which flows northerly into the Bruneau and thence into the Snake, is one of the few streams in Nevada whose waters find their way out of the State. The Jarbidge is a swift-flowing stream, having nearly the same volume as Clear creek, in Colorado. The canyon in which it flows is 400 to 600 ft. wide, and has a bed of gravel and sand, the bedrock of which has not been explored. The sides of the canyon rise to a height of 1500 to 2000 ft. above the stream, but the slopes are not too precipitous to be readily climbed in most places. In the river-bed and on the mountain sides are growths of mountain mahogany, cedar, pine, and some cottonwood trees. The entire section, embracing both slopes of the Jarbidge range, is within a National Forest, and persons wishing to cut trees for tent poles, cabins, and mine timbers are required to secure permits from the local Forestry official.

Jarbidge, Nevada, March 10.

The country is covered principally by rhyolite, in which are, apparently, some dikes of andesite and dacite. Cutting through this formation are numerous dikes of silicified rhyolite and quartz which carry the gold and silver of the camp. The croppings of the latter dikes, or lodes, are very prominent, in some instances protruding from 5 to 30 ft. above the adjacent surface. On the east side of the Jarbidge are three of these outcropping veins, more conspicuous than the others, which strike northwest; they are cut obliquely by the stream. The

one farthest north is now known as the Bourne lode, the 11 claims on and contiguous thereto having been located by D. A. Bourne in August, 1909. The next lode, or zone, paralleling the Bourne, is the Pavlak, five claims along which were staked in September, 1909, by Mike Pavlak and Peter Thourot. Still farther south, on the east side of the canyon, is the Pick and Shovel group, which was located at about the same time by John Escalon. The vein on the last named may or may not be the same as that of the Pavlak. Bourne, after making his locations, secured the co-operation of some Boise men and the North Star Mining Co. was organized to develop the property. J. E. Clinton, of Boise, is president of the company, and D. A. Bourne, manager. Mr. Clinton is a banker, and Charles Reynolds, a banker of Bruneau, is a stockholder and director. The only work thus far performed by the company consists of an adit 100 ft. long on what is considered the principal lode, some 30 ft. of cross-cutting from the adit, and a 15-ft. shaft on the same lode. F. V. Bodfish, of Victor, Colorado, who spent 12 days in the camp and thoroughly sampled this lode and had assays made, favored me with data showing the results of his investigations. In sampling what he considered as mill-dirt, not including picked specimens, he found that 13½ ft. of the surface outcrop averaged $8.54 per ton; that 11 ft. of cross-cutting from the main adit, neither wall exposed, averaged $8.50 per ton; that samples across one side of the shaft, that was sunk on the east wall, ran an average of $12.32 per ton. Assays of 23 samples from this lode gave results as low as 40c. and as high as $19.15 per ton. As showing exact results for gold and silver, 8 ft. of the outcrop gave 0.28 oz. gold, 1.88 oz. silver; 3 ft. more of outcrop gave 0.34 oz. gold, 0.9 oz. silver; the first 2½ ft. across the south side of shaft gave 0.92 oz. gold, 1.5 oz. silver; the next 2½ ft. showed 0.32 oz. gold, 2.40 oz. silver; the next 1 ft., 0.32 oz. gold, 0.5 oz. silver. Mr. Bodfish also made assays of picked specimens from the Bourne lode, six of which assayed as follows: $64.50, $88, $211.-93, $305.90, $151.60, $414. He believes the Bourne orebody is a lode in the rhyolite, with defined walls, that its strike is south 40° east, dip 80° east, and its probable width 30 ft. Free gold is visible in some of the ore, and may usually be obtained by crushing and panning. The highest-grade ore occurs in dark streaks in the quartz, in which the gold is associated with sulphide of silver. There are those in the camp who assert that they find petzite in the ore, though experienced assayers here have failed to find it. Three supposed high-grade specimens from the Pavlak gave $13.44, $35.60, $12.90; two from the Pick and Shovel ran $42.24 and $46.70 per ton. Mr. Bodfish is of the opinion that there is a mineralized zone, in which is embraced the principal lodes, which has a length of 12,000 ft. The Bourne company is undertaking the development of one part of the group, and has let a number of leases on other parts. The first lease was let to Frank W. Riddle, of Twin Falls, and he is starting systematic work. The second lease was let to Roberts & Lamb, who have begun work. Ten or twelve other leases have been given, and most of these lessees were to make their selections April 10. Among these are Wyman & Wyman, of Boise; P. L. Williams, of Salt Lake; and others from Goldfield. Some of the leased ground covers what appears to be cross-veins or spurs from the principal lode. The small amount of work performed, however, makes the system of veining uncertain.

The Pavlak group has been bonded to the Pavlak Mining Co., in which Coburn & DeWitte, and Brunn, Kinney & Co. are principals, the price named being $100,000, a payment of $10,000 to be made in May. The outcropping vein on this group is a strong one and seems well defined, but the development is very limited. A cross-cut has been started from the base of the mountain, on the river, which is expected to intersect the vein by driving 400 ft.; this will give about 600 ft. of backs. The Twin Falls Jarbidge Development Co. holds a bond from John Escalon on the Pick and Shovel group at $100,000, a payment of $2000 having been made. A shaft is being sunk on the foot-wall of the vein, with the idea of driving cross-cuts from it to the hanging wall of the vein at various depths. This plan assumes that the vein dips east. This vein runs nearly parallel with the canyon at this point, and ample opportunity is offered to obtain great depth by driving cross-cuts to the vein from the side of the canyon. The characteristics of the ore at the Pick and Shovel and Pavlak are similar to those at the Bourne, and so far as can be ascertained the value of the ores is much the same. There is a large area here that is attractive to prospectors. The streams head in snowy basins near the summit of the range, each cutting deeply into the formation. Bear creek is one of those streams. It runs almost parallel to the Jarbidge for some distance before making a turn to the east and into the latter. The high ridge between the two canyons is marked by east and west andesite dikes, which also extend westerly from Bear Creek canyon. A part of this area is covered by the group of the Belmont Mining Co., in control of W. A. Stevens and associates, of San Francisco. Some work is in progress here; one adit is being driven easterly and another westerly from the bed of Bear creek. Assays obtained here make it seem worth while to continue development. Mr. Stevens spent two months in camp last fall and has done a great deal of prospecting and testing. Information obtained at the district recorder's office was to the effect that over 500 claims have been staked and filed for record in the district. Aside from the ore obtained on the three most prominent veins in the camp—Bourne, Pavlak, and Pick and Shovel—there seems to be gold-bearing ore distributed over a wide area where quartz croppings occur. At the time of my visit there were hardly 20 men at work on all the claims of the camp. It is but fair to say, however, that work has been held back till the wagon-road from Jack Hole was finished and until finances were arranged. Many claims were staked by men who will do little in the way of actual mining, as they not only lack the means but are without experience. Probably the proportion of this class is not greater here than it has been in other new camps. Mine operators of Colorado, Utah, Ne-

vada, and California, have sent representatives to examine the district but before much capital takes hold it will have to be developed to some extent by those now in control. Present development amounts to but little, as practically no depth has been attained. The preliminary showing made thus far would seem to make development worth while. Claim holders have exaggerated ideas of the value of their ground, which causes hesitancy on the part of those whose business is mining. There are those who would take a bond and agree to expend a certain sum in development, but in most cases the claimant wants a good payment down. Among those in the camp looking it over at the time of my visit were P. L. Williams, Salt Lake; C. Tillery, Charles Howbert, F. V. Bodfish, Cripple Creek; Dr. Bowes, Marshall Bond, and Ben Luce, of Goldfield; W. A. Stevens, of San Francisco.

The properties and ores above described are considered typical of the district and for this reason the data given may be of interest. There are five assay offices in the camp, established by Price & Beadles, W. D. Greene, George H. Wyman, Dr. Brownfield, and A. D. Sly. Mr. Beadles spent the winter in camp. Among the surveyors and engineers are William Neilson, W. W. Fisk, H. W. Horn. There are eight or ten stores, as many restaurants and sleeping tents, and a dozen saloons, whose sales of liquors are confined to bottled goods, the Government restricting them thus because the town is in a Forest. It is astonishing to see how many bottles the saloon men have of the right size to hold each a drink. The name 'Jarbidge' is a 'metamorphosed' Indian name: the red man called it 'Ja-ha-bich'. The population of the camp is about 800 to 900, and while some are leaving, about 20 to 30 per day are coming in. For the man seeking employment Jarbidge is a poor place at present. Predictions concerning a new mining camp are often hazardous, but it looks now as though Jarbidge might yield good quantities of milling ore.

Coal-land withdrawals were made during the year ended March 4 covering 7,675,000 acres not previously withdrawn and the form of withdrawal affecting an additional 9,000,000 acres was changed to cover all forms of entry instead of coal entry alone. The new regulations of April 10, 1909, for the classification and valuation of coal lands, materially increased the sale price of these lands and fixed more definitely the standards of coal classification. Thus, for example, under the old regulations, in eight widely separated townships the total area classed as coal land was 66,320 acres and the sale price was fixed at $2,088,600, whereas, under the new regulations, the area in the same eight townships classed as coal land is 126,663 acres and the sale price is $15,777,668—an increase in area of over 100 per cent, and in price of over 600 per cent.

Transvaal gold mines in the fiscal year, 1908-09, paid £9,338,691 for supplies and £11,039,106 for labor. The latter included European salaries and wages, £6,556,658; wages to colored persons, £4,181,894; wages to Chinese, £290,554.

Taylor Peak Iron Deposits

By E. C. Harder

*The Taylor Peak district lies in the eastern part of the Elk mountains on the boundary between Pitkin and Gunnison counties, Colorado. The nearest railway station to the north is Aspen, about 18 miles distant, on the Denver & Rio Grande and Colorado Midland railways, which may be reached by way of Ashcroft. To the south are St. Elmo, Quartz, and Pitkin, about 45 miles distant, on the Colorado & Southern railway, which may be reached by way of Dorchester and Tincup. The ore deposits are situated on the north, east, and south sides of Taylor peak, about ten miles west of the junction of the Elk and Sawatch ranges. They are all above timber line, ranging in elevation between 12,000 and 13,000 feet.

Geologically the district is composed of Cambrian, Silurian, and Carboniferous sediments resting on pre-Cambrian granite and irregularly intruded by a fine-grained diorite of Tertiary age.

The sediments have the following succession:

Carboniferous: *Maroon conglomerate*, 4500 ft. Conglomerate and sandstone, with local limestone layers. *Weber formation*, 100 to 550 ft. Dark shale, with limestone layers. *Leadville limestone*, 400 to 525 ft. Blue limestone.

Silurian: *Yule limestone*, 350 to 450 ft. Limestone with upper shale bed.

Cambrian: *Sawatch quartzite*, 50 ft. Quartzite with thin conglomerate at base.

Pre-Cambrian: Granite, gneiss, and schist.

In general the distribution of formations is as shown in Fig. 1.

The pre-Cambrian granite occupies the eastern part of the district and the intrusive diorite the western part; between them is the belt of Paleozoic sediments, the oldest on the east, narrowing to a thin strip on Taylor Peak. The sediments have a general westward dip of 25 to 45°. To the west of the district the diorite is in contact with the Maroon conglomerate, the uppermost Carboniferous formation of this region, but near Taylor peak it comes into contact with the underlying Weber formation and is very near the Leadville limestone. On account of the proximity of the intrusive rock, the Leadville limestone and the limestone layers in the Weber formation are locally recrystallized and replaced by iron ore. The Leadville limestone is very coarsely crystalline in places near the diorite contact. Where not so coarsely crystalline it shows numerous needle-like crystals of tremolite. Except for the formation of ore deposits the shales of the Weber formation show but slightly the effect of the intrusion. The limestone layers in the Weber, however, have been recrystallized, though not so coarsely as the Leadville limestone. Near the ore deposits both formations are deeply stained by iron.

The ore deposits are situated at or near the contact of the sediments with the intrusive diorite, the actual location being determined by the kind of rock and probably by fracturing and faulting. The

*Abstract from 'Contributions to Economic Geology, 1908,' U. S. Geol. Surv., Bull. 380.

largest single deposit (Fig. 2) lies near the head of Cooper creek, on the northwest slope of Taylor peak, about 3½ miles south of Ashcroft. It is situated near the contact of the Weber formation and the Leadville limestone, being a replacement of both, and is 500 ft. from the diorite contact. This deposit is irregular, containing horses of quartzite, shale, and limestone and having stringers that extend into the surrounding limestone area. It is situated on a slope of 35 to 45° and is opened by several horizontal tunnels, three of which, having a length of 70, 110, and 120 feet, end in limestone. Whether this limestone is merely a horse or whether it is wall-rock is not known, but if it is wall-rock a large part of the present body of ore is merely a surface covering. In the limestone area surrounding the deposit there are numerous veins of iron ore and bodies of limestone and shale partly replaced by iron. The ore is mainly a dark blue, glossy magnetite with calcite, quartz, pyrite, kaolin, siderite, barite, and chlorite as gangue minerals situated in cavities or disseminated. The gangue minerals are most abundant near the limestone contact. Locally pyrite is present in such quantities as to become injurious. In places the ore is soft and friable, but mainly it is dense and hard. Near the surface it becomes more porous, owing to the leaching of gangue minerals, and is stained by limonite. The limonite originates partly from the oxidation and hydration of magnetite, but mainly from the oxidation and hydration of pyrite; indeed, considerable partly altered pyrite is present near the surface.

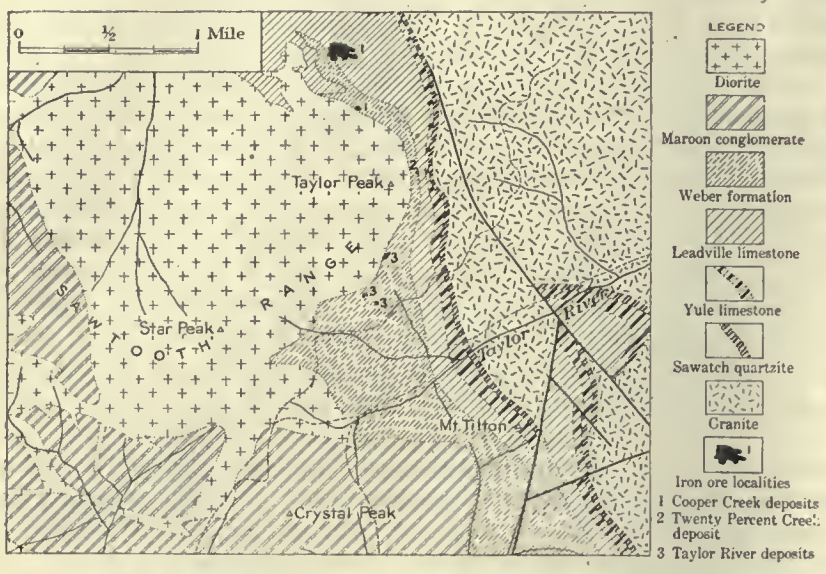


Fig. 1. General Geological Map of the Taylor Peak District, Showing Iron-Ore Deposits.
From Anthracite-Crested Butte Folio With Additions and Revisions.

The contact of iron ore and limestone has commonly a very steep dip—from 70 to 80° toward the iron—but in places the dip is as low as 35°. The limestone is hard and crystalline within a few feet from the contact, and much of it contains veins of calcite. At the contact it is soft and friable and is mixed with gangue minerals and seams of magnetite and limonite. On the iron-ore side of the contact the gangue minerals gradually become less abundant and within a short distance give place to solid magnetite. Near the contact the ore is generally soft, but the main part of the orebody is dense and hard. The sediments surrounding the ore deposits contain veins and stringers of iron for a distance of several hundred yards, and close to the deposit they are deeply stained and here and there partly replaced by iron. Halfway between the main deposit and the summit of Taylor peak is a small deposit at the contact of the diorite and the Weber formation. (See Fig. 2.) This deposit contains two kinds of ore—a dense blue magnetite and a mixture of magnetite and limonite with partly replaced sedimentary material. Both kinds are present at the surface; the former probably represents the replacement of a pure limestone, and the latter shows the less thorough replacement of a shaly limestone. The surrounding sediments are stained and partly replaced by iron, but the

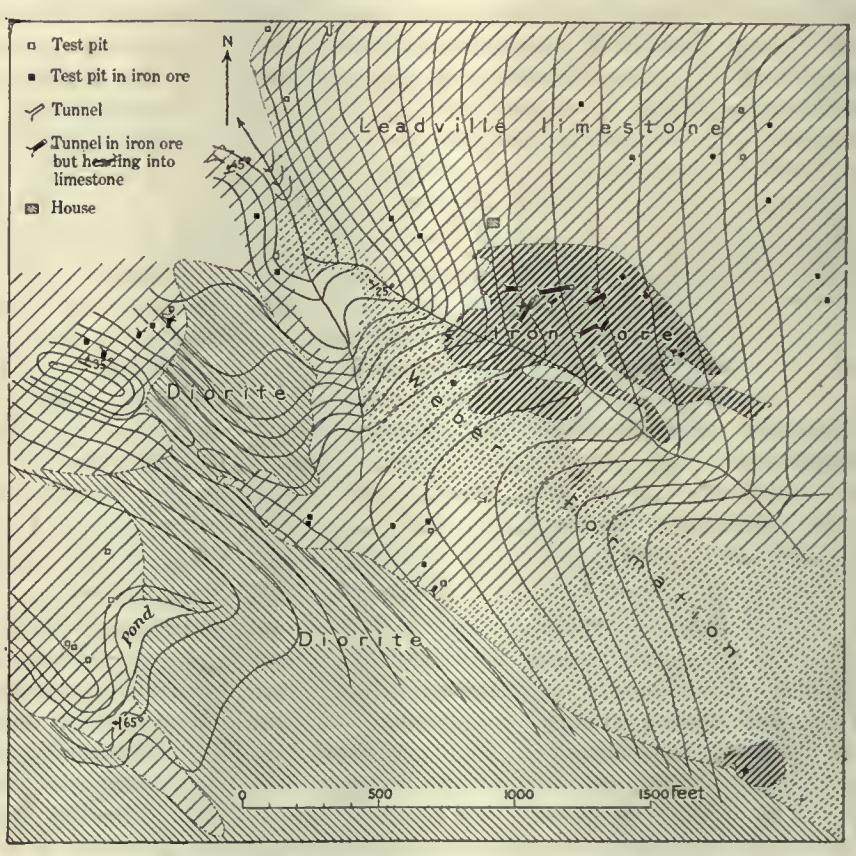

Fig 2. Detailed Map of the Cooper Creek Iron-Ore Deposits.

diorite shows little or no change near the contact. The gangue minerals here are mainly calcite and quartz. Another small deposit lies at the contact of the diorite and Weber formation on the east side of Taylor peak, near the head of Twenty Percent creek. (See Fig. 3, *a*.) This deposit is similar in every respect to the one just described, being the replacement of a local limestone area in the shale-limestone formation. On the southeast slope of Taylor peak, above Taylor river, there is a series of small deposits in the Weber formation at or near the diorite contact. (See Fig. 3, *b*.) The character of the ore here is the same as in deposits previously described, but the association of gangue minerals differs in some of them. In the deposit farthest to the north, a short distance southeast of the summit of Taylor peak, the ore is heavily impregnated with chlorite and contains some calcite, and directly at the contact there is an association of pyroxene, amphibole, garnet, epidote, and pyrite in a cherty matrix. The diorite at the contact is finer grained than usual and contains seams and specks of pyrite.

The iron ore is intimately associated with sedimentary material, occurring as local replacements, stains, and small veins. Where the original rock was sandstone or shale the ore is very sandy, some of it being so lean as hardly to be called an iron ore. Most of the deposits, especially the replacement deposits, are very near the diorite contact, but veins of magnetite, limonite, and locally pyrite occur in the sediments at some distance from the igneous rock. Near Star peak in the Sawtooth range the diorite contains included masses of silicious shales from the Weber formation which have been deeply stained and contain little seams of magnetite a few inches in thickness and one or two local areas of ore a few feet in diameter at the contact with the diorite. On account of the color the whole mass has been considered iron ore.

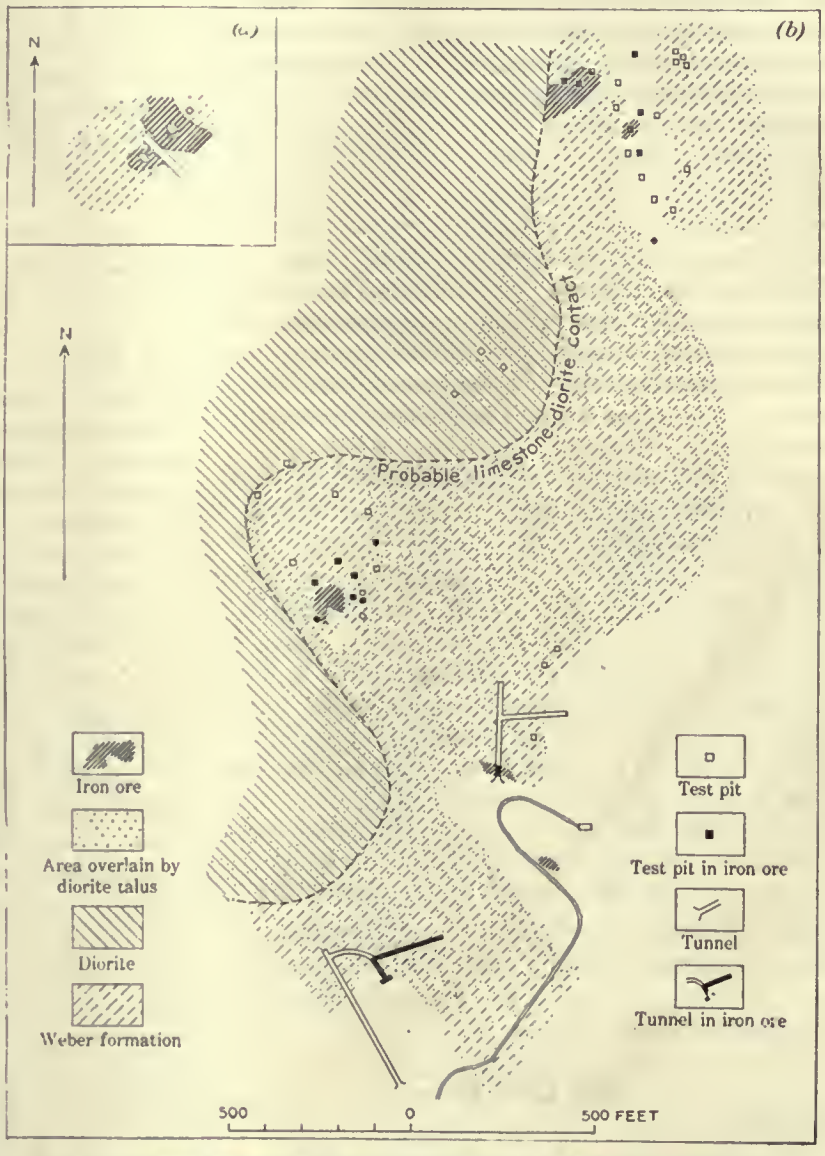

Fig. 3. Detailed Map of the Twenty Percent Creek (a) and Taylor River (b) Iron-Ore Deposits.

In general, then, the ore follows the diorite contact, replacing the calcareous portions in the adjacent Weber formation or the Leadville limestone where this is close enough. This association shows that the ore-bearing solutions were derived from the diorite, and the nature of the gangue minerals shows that they had a deep-seated source. The deposits are unfortunately situated with regard to topography and railroads. Aspen, the nearest railroad station, is 18 miles north of and 4000 ft. lower than the iron ores. Under great difficulty a branch line might be constructed to a point within a few miles of the Cooper creek deposits if they were extensive enough to warrant the expenditure, which is not the case. The Taylor river deposits are several miles beyond Cooper creek, on the other side of the Elk Mountain divide, and would have to be transported by way of Taylor river to the Colorado & Southern railway. It is practically impossible to contruct a railroad nearer than two miles from either of these deposits, as they are well up on the slope of the mountains and can hardly be reached by wagon. Unless the price of ore rises so as to make a 15 or 20-mile haul by pack animals and wagon profitable or a cheap method of transportation is installed these deposits will probably not be utilized. The Cooper creek deposit is by far the largest in the Taylor Peak district. Measured on the slope (35° S.W.) it has an average width of 450 ft. north and south and an average length of 750 ft. east and west. Three horizontal tunnels have been driven through it into limestone, so apparently a large part of the deposit is merely a surface blanket. With the average depth as shown by the tunnels, the quantity of ore may be estimated as being between 3,000,000 and 4,000,000 tons. Doubtless, however, portions of the deposit go to a much greater depth than the explorations indicate, so that a larger tonnage than that may be expected. All the other deposits should be measured in thousands rather than millions of tons.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Ten Mill District of Idaho

The Editor:

Sir—In connection with the recent 'stampede' into the Ten Mile district in Idaho county, Idaho, the statement has been made in Spokane, Washington, papers that the discoveries are in veins traversing a belt of quartzites said to be indistinguishable from those of the Burke section in the Coeur d'Alene district. The geology of the new camp might as well be correctly stated. I made a recent visit to a portion of the Ten Mile district, and all the rocks I saw were gneisses, schists, granites, diorites, and pegmatites, strongly resembling the Archean rocks of the Idaho Springs, Central City, and Georgetown mining districts of Colorado, and quite unlike the Belt series of rocks as represented in the Coeur d'Alene. The older members vary from typical gneiss to mica schist at one extreme and a rock containing so little mica that it resembles a quartzite at the other extreme. These rocks are contorted and much broken by intrusive granite which itself has a gneissic structure in places. The whole complex is intimately intruded by pegmatites. Some diorite dikes occur but are not prominent. The quartzite-like bands have a prevailing northerly strike and the predominant vein system in so far as I got acquainted with it cuts them at high angles. But the walls of the veins are as frequently pegmatite or typical gneiss as they are of the quartzite-like rock. This Archean area is apparently much more extensive than the Ten Mile district, and contains mines elsewhere. In short, there is nothing in the geology of the Ten Mile district that is peculiar to it. The district is simply a portion of the gold-bearing Archean area of central Idaho neglected until recently.

Coal Land Prices

The Editor:

Sir—Though heartily in agreement with the general conclusion in your editorial of April 2, regarding the higher prices now asked for Government coal lands, I wish to criticise the statement that a higher price for land means dearer coal for the consumer. According to Ricardo's law of rent (which is generally accepted by economists), the price of any commodity, like coal, depends upon its cost of production at the leanest mines necessary to work to supply the market demands. The coal at these leanest mines, which are those "on the margin of production," is worth nothing in the ground as its selling price only covers the essential costs of production such as wages, supplies, and the interest and renewal of the capital invested in improvements and machinery. It is only at richer mines, where a surplus remains above the essential costs, that the coal has any value in the ground or any royalty can be obtained from the operator by the fee-owner. Hence a royalty on output, or its capitalization in the price per acre of coal land, represents a residual, not an essential, factor in cost of production and can not affect the price of coal to the consumer. If the Government does not retain the royalty for the people, either by lease or by a higher initial price for the land, it will be absorbed by private interests to the detriment of the revenue. In two cases my statements should be modified. First, where all the available coal land is controlled by one corporation as is thought to be the case with Pennsylvania anthracite. Here the price to the consumer is not the essential cost of production at the marginal mine, but 'what the traffic will bear'. Second, where present marginal or even sub-marginal coal land has a speculative value based on the possibility of cheapening working costs so as to leave a surplus for royalty.

Leasing Public Oil Lands

The Editor:

Sir—There is one point in Mr. Johnson's letter regarding Senate Bill No. 5488, published in your issue of April 16, that does not seem to me to be well taken. He says, "Any operator who will pay the Government a rental year by year to protect a lease is performing a service for conservation and should not be disturbed." This dictum appears to be directly opposed to the well known principle of the conservationists that private owners should not be allowed to obtain control of mineral lands merely to hold them for speculative future value. If the law permits a lessee to hold his lease without operating, it permits him to violate this principle. I do not wish to be understood as favoring any law that would compel wasteful methods as do some of our present laws, but I certainly am opposed to a law which would enable anyone, corporation or individual, to curtail production for speculative purposes. The principle of "dig or get off the dump" that has been discussed in connection with the annual assessment work on lode claims is equally applicable to oil, coal, and phosphate lands. If a lessee does not want the land in question for immediate use, why permit him to hold it and thereby keep others from utilizing it? Certainly the keeping idle of mineral lands that might be productive is to be deplored and the laws should be framed to prevent it. If, in special cases, it is desirable to allow a lessee to hold mineral land in idleness the rental for such idle lands should be greater than for similar lands that are being worked, great enough to be prohibitive if extended over any considerable period of time. Perhaps the best thing that could be done would be to leave the question of the use of leased lands in the hands of an executive officer having full power to deal with each case on its individual merits. The success or failure of this scheme would depend wholly upon the character and ability of the man holding the office.

Colorado Springs, Colorado, April 21.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Panama Canal excavation during March totalled 3,067,479 cu. yd., a daily average of 117,980 cu. yd. for the 26 working days. The amount of concrete laid during the month was 90,502 cu. yd. and 571,293 cu. yd. of fill were placed. The rainfall for March was 3.78 inches.

Management of men is an important factor in costs. H. P. Gilette makes the following among other suggestions. Group men in gangs according to their respective energies, and so plan the work as to make each gang as small as is consistent with efficient work. Then pay these gangs according to the number of units of work done by each.

Heat received by the earth under a high sun and a clear sky is equivalent, according to the measurements of Langley, to about 7000 hp. per acre. Though engineers have not yet discovered how to utilize this enormous supply of power, they will ultimately succeed in doing so. When that comes about centres of industrial activity may perhaps be transferred to the burning deserts of the Sahara, and the value of land determined by its suitability for the reception of traps to catch sunbeams.

Radioactive substances are constantly giving out large quantities of heat, presumably at the expense of their potential energy; thus when these substances reach their final non-radioactive state their potential energy must be less than when they were radioactive. Rutherford's measurements show that the energy emitted by one gram of radium in the course of its degradation to non-radioactive forms is equal to the kinetic energy of a mass of $^1/_{13}$ of a milligram moving with the velocity of light.

Tropical trees do not generally cut up into good fuel. Many of them are too hard or too twisted to be split economically. In one instance, where the amount of fuel per acre was estimated as by temperate zone standard, subsequent results showed that only 20% of the estimated amount was actually cut and corded up as fuel. The rest could not be split economically or was not worth cutting. This is a serious consideration where a steam plant is used, for it means that accessible fuel is soon exhausted and that it must then be hauled for a considerable distance.

In cyanidation of slimy material the chief difficulty is removing and obtaining the dissolved gold, or silver, from the slime. Many methods have been tried, and the ones chiefly in use today are the well known decantation process and various filter-press processes. The decantation is very slow, and, therefore, requires an enormous plant, and a large quantity of solution has to be handled in proportion to the weight of slime treated. The filter-press method has many advantages, but it requires a costly plant, and necessitates much handling and constant renewals.

Graduates of French engineering schools are to be sent to this country by the French Government to work for two years each in bridge-building and mining plants. A commission of two French engineers, Jules Boenfve and Henri Vetillart, who have been appointed to find places for the graduates, arrived in New York City recently. Four students will be sent over each year and will work here for two years at a nominal salary, after which they will return to France in the service of the French Government.

Fishes were already well established and distributed over perhaps the greater part of the northern hemisphere at the beginning of Devonian times; and then there began suddenly a remarkable impulse toward the production of lung-breathers, which is noticeable not only in Europe and North America, but also probably so far away as Australia. In the middle and latter part of the Devonian period, most of the true fishes had paddles, making them crawlers as much as swimmers; many of them differed from typical fishes, while agreeing with lung-breathers, in having the basis of the upper jaw fused with the skull, not suspended; and some of them exhibited both these features.

Dry-rot fungus sometimes infects wood before it leaves the forest when felled timber remains stored there for some time. The first evidence of such infection is indicated by the presence of red stripes in the sawed wood. If such wood is thoroughly seasoned the mycelium present in the red stripes is killed. If the seasoning be neglected or imperfectly done, the mycelium, which possesses the power of remaining in a latent condition for some time, commences active growth when the wood is used in any part of a building where it is exposed to dampness, and this in some cases is unavoidable, as when the ends of joists are built into a wall. Under such circumstances dry rot eventually appears.

Pre-Cambrian is a term used by the United States Geological Survey to include all rocks supposed to have been in existence before those laid down in the Cambrian period, at the beginning of the Paleozoic era. In the early days of geological study all these pre-Cambrian rocks were supposed to be of igneous origin and to record a time before life on the globe began. Later, when both sedimentary beds and fossils were discovered in them, they were subdivided, usually into two variously named systems, the older of which, now generally known as the Archean, was supposed to be destitute of life and sediments, while the younger, now called the Algonkian, was supposed to mark the earliest beginnings of both. More recently sediments have been found and fossils suspected in certain Archean rocks, so that the distinction between these two great systems now depends on other points of difference, most of which are not quite so easily grasped or applied. Nevertheless the subdivision is useful, since the Archean and Algonkian are separated from each other by a great 'unconformity' and differ from each other physically as much as the Algonkian differs from the Cambrian.

Special Correspondence

SALT LAKE, UTAH

Ohio Mine and Mill.—Bingham Mines Co.—U. S. S. R. & M. Co. Mill.—Electrostatic Treatment of Zinc Ore.

The steel structure for the concentrating plant of the Ohio Copper Co. was designed and built for four units, each to have the capacity of 625 tons per 24 hours. The first two units of machinery were installed and set in operation late last year; the third and fourth units, foundations for which were originally laid, are to be installed later, some of the equipment having been provided. The plant was designed by W. A. Kidney and assistants, the former now being superintendent. The two units in operation are treating 1250 tons of ore every 24 hours, and Mr. Kidney believes the complete plant will be equal to the capacity of 3000 tons. The ore is received into cars at the base of the 1400-ft. incline which leads from the levels of the Cunningham adit to the level of the great Mascot tunnel. These cars are brought out in trains by electric locomotives through the great tunnel which has a length of 14,000 ft. The tunnel trackage is extended half a mile from the portal to the mill, the last 600 ft. being supported by a high steel trestle, by means of which the cars of ore are dumped into the mill-bins. The Mascot tunnel, its trackage, and ore-hauling facilities are owned by the Bingham Central Railway Co., in control of F. A. Heinze, who is also supposed to be the controlling spirit in the Ohio Copper Co. At present most of the ore received at the mill is taken from the level of the Cunningham adit and those above it, and consists of chalcopyrite, chalcocite, and copper oxides in a quartzite gangue. When later the ore shall come from levels below this it will contain practically nothing but sulphides. In anticipation of soon getting into the strictly sulphide bodies the mill was equipped with jigs for coarse concentration; but by reason of the present mill supply containing so much oxidized stuff the jigs are not now in use.

The ore in the receiving bins passes to a crusher of sufficient capacity to serve two sections of the mill, reducing the ore to 2-in. size. The crushed ore for one section passes through trommels, the oversize passing to a 20 by 6-in. Blake crusher by which it is reduced to ¾-in., the undersize joining the crushed ore in the boot of an elevator by which this material is raised to the top of the mill and fed into two double trommels—two in tandem. The fine from these is re-crushed by two sets of 36 by 15-in. Allis-Chalmers rolls; the oversize is re-crushed by one set of rolls of same size. The entire roll product now passes to four 7-ft. Monadnock Chilean mills, sold by the Trent Engineering & Machinery Co., the pulp coming to these mills through a distributing box that permits the lighter slime to overflow and go to hydraulic classifiers. The Chilean mills further reduce the pulp to about 24 mesh, the screens being of No. 28 and 29 wire. As an experiment one of these mills is being operated with only two rollers. M. P. Boss, who is interested in some of these experiments, thinks there is an advantage in allowing the pulp to partly settle in the mortar bed between rollers, and that this is accomplished by running with only two. The Chilean mill product now flows through a system of distributers to 27 V-shaped hydraulic classifiers for the two sections of the mill. These classifiers are built in three sections of nine each, each section occupying a bench with the concentrating tables. Each classifier, which has a length of about 12 ft., has two spigots, through one of which the coarse material feeds upon a table, and through the other the fine stuff feeds to another table. On the first, or highest, bench are James tables and Wilfleys; on the second and third benches are all Wilfley tables. There is a fourth bench of tables over which the middling from all the tables above is re-concentrated. Finally, the concentrate from all these tables is re-concentrated over the fifth bench of Wilfley tables, giving a shipping product that runs 17% silica, 27% iron, and 23% copper. The slime that overflows from the hydraulic classifiers, and the tailing from the concentrators, pass through a launder to the slime plant, where they undergo treatment by 90 Callow classifying tanks, the thickened slime being then passed over Wilfley tables; the slime from the tables and tanks goes to six buddies, each 20 ft. diam., having concrete surface with an inclination of 1¼ in. to the foot, and a speed of 1 rev. per min. Reverting to the first part of the process, the crushers and rolls crush wet, though it is proposed to operate them dry later. The concentration is in the ratio of 24 to 1 and about one-tenth of the product is obtained in the slime-plant. The tables that re-concentrate the middling from all the other tables make no tailing, nor do the tables that re-concentrate the concentrate; the reject from these is forced up to the Chilean mills by sand pumps. For January and February the recovery in the shape of a concentrate product represented 71% of the value as shown in the heads. The mill machinery is electrically driven and the water supply is taken from the Mascot tunnel. The town and settlement in the vicinity of the Mascot entrance and the Ohio Copper mill is known as Lark. It faces Salt Lake valley.

The Bingham Mines Co., managed by Imer Pett of Salt Lake, is operating on the old Dalton & Lark group, on which are opened the Lark, Brooklyn, and Lead Mine veins, which strike northeast and have a dip of 40° northwest. The ore is found in limestone bands in a quartzite country yielding a copper, lead, and silver ore. These properties are now entered through the Mascot tunnel. A cross-cut, which starts on this tunel at a point 10,000 ft. from the portal, was driven 900 ft. to the Brooklyn vein, on which a drift was run 1200 ft., almost to the old Brooklyn shaft. J. E. Bergh, superintendent of the property, states that shipments amount to 700 tons per month. A recent shipment of one carload sampled 25 oz. silver, 5.6% copper, and 30% excess of iron. Some of the shipments contain 25 to 30% lead. This company owns the Commercial mine, situated on the Bingham canyon side, and from it shipments of 100 tons per day are made. Joseph Hyland is superintendent of the Commercial.

The milling plant of the United States S., R. & M. Co., at Midvale, is treating 250 tons per day of lead-zinc-iron ore, supplied by the company's mines in Bingham district. The methods involve concentration by jigs and tables, followed by drying the zinc-iron concentrate and passing it through Huff electrostatic separators, parting the iron from the zinc. First, the ore is run through a crusher, then elevated and passed through a trommel having ¾-in. perforations, the undersize passing to the bins, and the oversize to 12 by 30-in. rolls, the crushed product of the latter going to the same bins. The material in the bins is then elevated again and reduced by a second set of rolls and screens to $^5/_{16}$-in. size, and then by similar methods is sized for the jigs into four grades, which are $^5/_{16}$-in., 6, 8, and 10 mesh. The jig product is a lead concentrate, and it amounts to 65% of the concentrate product of the mill. All the jig tailing is further pulverized to 10 mesh and passed over Wilfley and Overstrom tables, the first 11 tables making a lead concentrate and a zinc middling, the latter being re-concentrated by six other tables. The table tailing is passed to a 4 by 16-ft. tube-mill, by which it is reduced to 30 mesh, and thence through a Richards classifier to six Wilfley tables, making lead and zinc concentrate. The slime is finally treated by seven Sherman slimers. The zinc-iron concentrate and zinc middling are then taken to the electrostatic section of the plant. They are first put through two Bartlett & Snow dryers, whereby the 12% moisture contained is entirely eliminated. The product then passes through an automatic feeder into the first dryer, from which it is conveyed to an elevator and by the latter it is dumped into the second dryer. This material, as it comes from the concentrating plant, carries 21 to 24% iron, 4 lead, 20 to 23 zinc, 5 silica, 2 lime, and, approximately, 30 sulphur. After being dried it is sized and graded for the electrostatic machines by means of a series of impact screens; the coarsest of these grades, containing about 32% iron and only 7 zinc, is held out and sent to the smelting plant. The finer screen sizings that follow

result in making three grades—first, the oversize of 30-mesh, the oversize of 60, and that which will pass 60-mesh screens. The electrostatic plant consists of five units, each unit being made up of three machines—one 'rougher' and two 'finishers.' The resulting zinc product contains 52% of that metal, and 4% iron; the iron product still contains about 9% zinc. The plant can handle 48 tons per day. J. R. Mougin has general charge of the milling plant, O. M. Cozzens being foreman of the concentrating section, with Allan McOwen at the electrostatic plant.

MEXICO

Greene-Cananea Improvements. — Amparo. — Cinco Minas. — Asientos Developments. — Mitchel Mining Co. in Receivers' Hands.—San Juan Litigation.

Arrangements for electric haulage of ore are being made by the Greene-Cananea Copper Co. The necessary equipment has been ordered, and within the next three or four months the ores of the Elisa, Capote, and intermediate properties will be handled by electric traction. New ore-bins are being constructed at the Capote mine, and from these bins the ores will be conveyed to the smelter by rail. The tunnel connecting the Elisa and Capote properties will be the route of the electric ore trains, and when an extension of this tunnel to the Henrietta mine is completed ores from the latter will be delivered also at the Capote bins. As further underground connections are made the electric haulage will be extended. The Greene-Cananea is now operating 6 of its 8 furnaces, and it is stated that the ore now being smelted is 25% richer than the greater part of that handled last year. The officers of the Lucky Tiger Combination Gold Mining Co. are anxiously awaiting the decision of the Southern Pacific directors in regard to the building of the projected line into Douglas and along the Bavispe river in Sonora. Such a line would give the company's rich El Tigre mine transportation facilities. If the Southern Pacific decides to postpone construction, it is stated that the Lucky Tiger may undertake the building of an electric line to connect with the Nacozari railroad. Power plans under consideration include a hydro-electric installation on the Bavispe river, or the erection of an oil-burning power-plant at either Izabel or Douglas. The capacity of the concentrating plant at El Tigre is to be increased from 100 to 250 tons daily. A zinc-separating plant similar to that in successful operation at the properties of the Calumet & Arizona Co., near Cananea, will be installed by the Santa Fe Mining Co., owning mines in the same section. The ores are similar to those of the Calumet & Arizona.

The Amparo Mining Co., the only American mining concern of the State of Jalisco now on a dividend basis, earned profits of ₱668,537 in 1909. The company's total revenue was over ₱1,500,000. The 50-stamp mill was in commission 344 days, crushing 63,398 dry metric tons of ore, which yield concentrate and bullion to the value of ₱1,400,017. High-grade ore shipped netted ₱44,048. The cost per ton of ore mined, milled, and marketed was ₱11.24. The ore in sight above the 700-ft. level at the close of the year was estimated at 360,000 tons, and the probable ore below that level at 350,000 tons. The company has ordered equipment that will increase its reduction capacity 1000 tons monthly. The Cinco Minas Co. (Marcus Daly interests), is preparing to ship high-grade ore from development work in the old Cinco Minas in the Hostotipaquillo district. It is expected to market about 100 tons monthly. A wagon-road to give the mines connection with the Southern Pacific is being built. A 25-ton experimental plant is in commission at the mines of the Regina Mining Co., in the Ameca district. This company is a recent re-organization of the Philadelphia Copper & Gold Mining Co. The Chapala Hydro-Electric & Irrigation Co. will be unable to deliver power to mining concerns of the Hostotipaquillo and Etzatlan districts until late in the year. This is a result of the recent agreement with the Guanajuato Power & Electric Co. for a division of territory, a clause providing for an exchange of power in emergencies, making necessary changes in voltage plans and equipment.

The Robert S. Towne interests have added to their extensive holdings in Mexico by leasing, for a period of 15 years, the properties of the Compañia Minera Leads Queen y Anexas in the Asientos district of the State of Aguascalientes. A royalty of 25% of the gross value of the ore extracted will be paid the owning company. The lease is with the Mexican Metallurgical Co., the Towne concern operating the San Luis Potosí custom smelter, and the products will be shipped to that plant. A concentrating plant may be erected. Walter M. Brodie, engineer for the Batopilas Mining Co., estimates that the Batopilas mines in Chihuahua have produced 23,000,000 oz. of silver in the last 30 years. The workings have a total extent of about 76 miles, inclusive of the stopes. Mr. Brodie reports that at the 100-stamp mill and concentrating plant, where direct water-power is used, crushing and concentrating is carried on at a cost of 80 centavos per ton. The mines of the Palmarejo & Mexican Gold Fields, Ltd., of London, at Chinipas, in the Arteaga district of Chihuahua, are to be immediately equipped with machine-drills. A new reduction plant with a capacity of 300 tons daily is planned, and construction may be started before the end of the year. Unwatering is in progress at the mines of the Parral Consolidated Mining Co., in the Parral district. The company's new concentrating plant, recently completed, will not be placed in commission until the unwatering is finished. The Mitchell Mining Co., a copper concern widely advertised a few years ago, which operated through subsidiary companies in the State of Guerrero, is in the hands of a receiver, Joseph F. Schwab having been appointed by a New York court. The appointment resulted from a suit brought by Frederick Cuthbertson in October, 1908, to recover $57,800. The subsidiary companies are the La Dicha Mining & Smelting Co. and the La Dicha & Pacific Railroad Co. Copper properties were acquired, a 200-ton furnace and 25-ton converter erected, and some copper produced. An 83-mile railroad to give the properties connection with the Pacific port of Acapulco was projected, and some materials purchased. Operations were suspended more than two years ago. The Mitchell Mining Co. was organized in 1902 with a capital of $5,000,000, and later this was increased to $8,000,000.

Part of Jalisco, Mexico.

The full text of the Supreme Court decision in the San Juan Mining Co. case, which has just been made public, shows that, contrary to general opinion, the Court went into the merits of the case fully, and that there is little possibility of further litigation. Juan Baigts, a Mexican, former owner of the San Juan mine in the Taviche district of Oaxaca, recovered possession of the property by suing the San Juan Mining Co., an American concern, in the Third Civil Court of Oaxaca. He based his suit on a clause

in the original contract of sale which provided that in the event a deal for the Escuadra mines, also in the Taviche district, was not carried out, the San Juan contract should not hold. The Escuadra deal failed, but the San Juan company, which had taken over the property from the men originally concerned in the negotiations, was in no way connected with it. The Supreme Court holds that the Oaxaca court, in returning the mine to Baigts, infringed Article 14 of the Constitution of Mexico, which deals with legal rights. The San Juan is the principal producer of Oaxaca.

BISBEE, ARIZONA

Railroad Extension to Gulf of California.—Gold at Altar and Quijotoa.—Ore Developments in Bisbee Mines. — Life of Mines.—Ore Shipments.—C. & A. Report.—Geological Work at Bisbee.—Copper Queen Benefit Association.

Within the last few days it has been rumored that the Sandoval-Henderson concession for a railroad across northwestern Sonora would be utilized by the El Paso & Southwestern giving it an outlet to the Gulf of California. The road will be constructed by a separate corporation, which, however, is said to be financed by Phelps, Dodge & Co. The terminus will be Puerto Lobos, on the Gulf, and the route will be by way of Caborca and Altar, Sonora, to Tucson, Arizona. The district of Altar is becoming celebrated for its placers, many of which contain gravel yielding more than $1 per cubic yard. There are also numerous quartz mines in the vicinity of Caborca which will become profitable when better transportation facilities are available. Farther west, between Caborca and the Gulf, are many partly developed copper deposits which are remarkable for their gold content. There has been an active movement of prospectors into the region through which the road will pass, and preparations are being made for the development of a town at Puerto Lobos, now called La Libertad. Reports of valuable placer discoveries at Quijotoa, 80 miles west of Tucson, have resulted in attracting many people to that district. Important locations of rich ground are said to have been made by a syndicate headed by S. W. Purcell, of Tucson. Quartz veins of great promise are also being developed in the same district.

Mining operations are active throughout the Bisbee portion of the Warren mining district. The Copper Queen is shipping to its smelter at Douglas about 2400 tons of ore per day that will average higher than 6% copper. The shipments in March reached 51,400 tons. The mixture of oxide and sulphide ores brings the average composition to approximately 18.5% silica, 9.3 alumina, 27 iron (metallic), and 17.5 sulphur. Recent developments of sulphide ores have been made in the bottom of the Sacramento shaft at a depth of 1700 ft. On approximately the same horizon a large stope of oxidized ore has been opened, containing considerable copper glance associated with the oxidized material. Development in the Copper Queen mines is proceeding at the rate of 5000 ft. per month, and the proportion of ore revealed per foot of development is somewhat greater than in past years. This is undoubtedly due to a better understanding of the geology of the district. Following the year's work by J. M. Boutwell, beginning in the autumn of 1908, a geological department was organized under the direction of Eugene M. Sawyer, aided by A. Notman, and M. J. Elsing, which has since continued the critical study of the Copper Queen holdings, with results that have proved highly advantageous. A detail survey of the whole area owned by the company has been made, and new workings are planned in view of the geological indications. The extent of the porphyry intrusive is much greater than was originally supposed. No general alignment is yet recognizable, but the trend of the orebodies in a southeasterly direction is a marked feature, with an important chain of small orebodies in a southwesterly direction as revealed by the workings from the Cole shaft of the Superior & Pittsburg company. While no large orebodies are yet reported from the Denn-Arizona, the most easterly mine in the group, significant discoveries of sulphide ores have been made, and active development is proceeding. For a time driving was done southward from the Denn shaft, but the larger work is now being conducted in the opposite direction, following near the Dividend fault.

To the west of the more northerly Copper Queen holdings great bodies of oxidized ores have been developed in the mines of the Shattuck-Arizona. At the present time this company is shipping 200 tons of oxide ore per day that averages 17% copper, and the quantity of lower-grade ore revealed is very great. Joseph Walker, the superintendent, is pushing development at these mines with great rapidity, and in a few months arrangements will be complete for making much larger shipments.

The Calumet & Arizona and the Superior & Pittsburg are adding immense bodies of ore to their reserves. These companies, which are operated by the same staff under the general management of L. W. Powell, also organized a geological department, originally under direction of W. B. Gohring, who has now become mine superintendent, he being succeeded as geologist by Ira B. Joralemon, aided by F. De Wilde and J. S. Olmstead. Development operations have been remarkably fruitful in these mines, and the amount of ore now known is greater than at any period in their history. The great mass of primary sulphide ore in the Oliver shaft of the Calumet & Arizona has been so far proved in an area 150 by 150 ft. on the 1350-ft. level. This extends up to the 1200-ft. level, and a drift at 1450 ft. has nearly reached the point where it should cut the orebody. In the Irish Mag the new development has been so successful as to leave that property potentially as important as it has been in the past. Extremely valuable developments are being made in the lower levels of the Junction mine, a Superior & Pittsburg property. A rich sulphide body, averaging about 10% copper, has been explored on the 1450-ft. level for a distance of 200 ft., with a width of approximately 65 ft. This orebody is unique, so far as this district goes, in having well defined hanging and foot-walls. The dip of the vein averages about 40 degrees. It has been penetrated by a drift on the intermediate level 50 ft. below, and it is also being explored on the 1300-ft. level. This ore consists of an extremely fine-grained compact sulphide of iron with chalcopyrite, rich in chalcocite, near the footwall where it will average 20% copper, the grade diminishing to about 6% toward the hanging wall. The work at the Junction shaft is under the superintendence of J. C. Collins. One of the largest bodies of oxidized ore today available in the Bisbee mines is in the Hoatson shaft of the Superior & Pittsburg. Recent work in the Biggs has shown extensive bodies of sulphide ore. Altogether the outlook for a long and prosperous existence of the Bisbee mines is better today, as judged by proved orebodies, than at any period in the past. Furthermore the work is being directed in the light of known geological relationships that render development less a matter of chance, and the discoveries of large masses of rich sulphide ore in the deepest levels yet reached increase the prospects for the continuance of mining here to much greater depths. There is no question that these lower ores represent primary sulphides. This fact, and the high copper content found, are full of significance for the future of Bisbee. It is interesting to note that in some of these deeper ores gold is found to the extent of 0.15 oz. per ton.

Greene-Cananea Concentrator.

MANILA, PHILIPPINE ISLANDS

Lode Mining in Benguet District. — Report by Division of Mines. —Bua Mining Co.—Benguet Con.—New Properties.—Oil Drilling.

At present the production of gold in the Philippines comes principally from the Benguet district where lode mining is carried on and from the Paracale district where dredging operations have proved successful. During the coming year lode mining should bring returns in Paracale and dredging will be further developed. The third gold mining district is Masbate in which development work has been going on steadily, and there is reason to believe that it will soon rank as a producing camp. An account of the dredging operations in Paracale was given in a recent article in these pages. Additional information regarding the Benguet district is now available. F. T. Eddingfield, mining engineer of the Division of Mines, has just returned from a short trip to Baguio, where he investigated the mineral districts to note particularly the progress in the work of mining and development. The following report has been given out by the Division and is preliminary to that which will appear later in the 'Mineral Resources'.

Although Benguet was the first district to begin successful mining, and is, perhaps, the most widely known of the Philippine mineral districts, little has been published up to the present as to the character of the deposits and of the work that has been done there. The mineralized district extends from the headwaters of the Antamok, on the north, to the headwaters of the Batwaan on the south; and from camp John Hay and the Bued river on the west for a distance of six miles to the eastward, thus comprising an area of about 45 sq. mi. The majority of the deposits are quartz veins, varying from 1 to 30 ft. wide, and in one case reaching 47 ft. They appear, for the most part, to be true fissure veins in andesites. Toward the south and west are reported contact deposits between andesite and diorite, and andesite and limestone. The classes of vein matter are white quartz veins, crystallized banded quartz, calcite, calcite and rhodochrosite, brown manganese and quartz, material which appears to be mineralized andesite, and brecciated material. Most of the ore is about 50% free-milling, but numerous veins are found which do not 'pan a color', but are high in telluride and kindred minerals. The veins have a general strike of east and west and a dip of about 60°, usually to the south. Most of the properties are easily reached by trail or wagon-road and are so situated that water-power can be utilized for running a mill. Labor seems plentiful and cheap, the average prices paid are:

	Per Day.
Common labor	₱0.70 to ₱1.00
Miners	1.30 " 1.70
Native carpenters	1.70 " 2.50
Japanese timbermen	1.70 " 2.50
Japanese carpenters	3.00 " 3.50
	Per Ft.
Contract labor:	
Prospect pits	₱1.00
Driving	5.00
Timber:	
Posts, 7 by 1 ft.	₱0.70 each
Lagging, 2 to 3 in. by 12 ft.	0.10 "
Sawed lumber	₱45 per 1000 ft.
Mining and milling	₱5 to ₱8 per ton.

Filipinos from other provinces are preferred to the Igorots for miners and millmen. They are steadier and better workmen. Japanese are used as timbermen in some mines on account of their greater strength and adaptability. The companies now existing are the Antamok Valley Mining Co., Madison Gold Mining Co., Bua Mining Co., Benguet Consolidated Mining Co., Igorot Mining Co., Muyot Mining Co., Major Mining Co., Copper King Mining Co., Camore Clayton Co., and Kias Hill Gold Mining Co. In addition the prominent groups of claims are: the Ebert, Topside, Vicente Volpiedad, Lorenzo Pau, McElroy, Calvin Horr, Murphy, Missionary, and McDill.

The only companies at present producing are the Benguet Consolidated and the Bua. The Bua is working two veins at Gomock, one a quartz vein 1 to 3 ft. wide, the other a rhodochrosite vein 3 to 5 ft. wide, striking N. 10° E. and dipping 65° to the south. The veins have been opened up by drifts for a length of 500 ft., and have been cut 100 ft. below by a tunnel 600 ft. long. They are working 54 Filipino miners, and 7 Japanese timbermen, and produce about 20 tons per day. The ore is mined by the system of overhand stoping, filling with waste broken during mining. The stope extends the entire 500 ft., and has ore-chutes every 30 ft. The ore is dumped into a bin near the mouth of the adit, from which it is trammed for a distance of about one kilometre to a second bin, which feeds into a two-bucket gravity aerial tramway, stretching across the Antamok valley to the mill. The mill is run by a waterwheel with a rope drive. It consists of six stamps with two copper plates. The tailing is cyanided, in six sand-leaching tanks,

Map of Northern Portion of Philippine Islands, Showing Location of Benguet District.

and then dumped into the river. The average value of the ore is said to be ₱14 per ton.

The Consolidated sustained severe losses in the cyanide plant during the baguio last fall and in consequence has reduced its output until the plant can be refitted. They had been working a good strong lode which is said to run ₱30 to ₱200 per ton. The lead was opened up on four levels 50 to 90 ft. apart, the lower levels being reached by a small incline shaft with a skip and an underground station. The usual feed of the mill was 20 to 25 tons per day. The ore was fed to a crusher, then to stamps and amalgamation plates. The tailing is classified and leached by a sand and slime leaching plant. The leached slime was filtered in a Ridgway vacuum-filter. The introduction of a vacuum-filter was a pioneer step in the Philippines and will, undoubtedly, lead to greater activity along the same line.

The Camote is one of the largest ore deposits in the district. The vein is manganese and calcite and is said to be 47 ft. wide. A large amount of ore has been developed and 1500 ft. of workings have been driven. It is said to 'catch ₱6.50 on the plates alone'. The company lost a 3-stamp mill in the landslide last fall but will undoubtedly erect another mill in the near future.

The Headwaters have put in 3000 ft. of drifts and adits,

showing four veins which run generally east and west, and dip 45°. They are working 44 men in the mine, 21 on road construction, and are preparing to install a 10-stamp mill of 1000-lb. stamps, tube-mills, a cyanide plant, and a filter-press. The Muyot is said to have 2400 ft. of drifts, adits, and raises, in a vein 4 to 30 ft. wide and averaging ₱6, and is at present working 60 Filipinos and two white men. The Madison has about 1000 ft. of work on two veins which are claimed to be the same as the Bua. The Topside has 500 ft. of work on two veins. The Copper King has 2000 ft. of work on four veins, varying from 2 to 10 ft. This ore contains lead, copper, and considerable free gold.

The Kelley group, on the north slope, has four veins: No. 1 running east and west and stands vertical; No. 2, N. 60° W., dipping 60° north, No. 3, S. 60° W., and No. 4, N. 34° W. If these directions are maintained the veins will all intersect. The intersection of No. 3 and 4 has already been opened. The outcrops of these veins are well marked. No. 1, particularly, shows as a strong high dike on the bank of a stream. Two thousand feet of driving has been done on the veins which vary from 4 to 10 ft., and are said to run ₱12 to the ton. They carry no free gold but are rich in tellurides. On the south slope Mr. Kelley has cut four more veins with 1500 ft. of workings. These veins run generally east and west and are from 2 to 16 ft. wide. About half of the gold in this group is free milling.

The Major Mines Co. has discovered a large number of veins on its property. The No. 3 vein on the Low Potential claim is most unusual. It is made up of bands of crystallized brittle quartz, separated by horses of andesite, and having a width of 4 to 10 ft. Most of the veins on this property pan high. When in full operation this company should be one of the largest producers in the islands. The Antamok Valley M. Co. has perhaps the largest holdings in Benguet with a large number of adits cutting some promising veins. Lorenzo Pau is working 12 claims; the Vicente Volpiedad, six claims with two or three good leads. Brown & Peterson are developing some ground. Calvin Horr has done a great deal of work proving up several good leads, one of which is 8 ft. wide, and is said to carry ₱8 in gold. The Camote Clayton, McElroy, McDill, and the other properties all have more or less work done. One company alone claims to have cut 132 different distinct veins on one group of claims: a most remarkable record. Some mills are already being erected in the southern part of the district.

The great number of veins, their uniform direction and their dip are significant facts. A peculiarity of the district is that the veins often occur in groups of four. The Division of Mines will have a party working in this field during April, May, and June, and the character of these deposits will then be carefully studied and the veins mapped. The geological map published in 1906 by the Division will also be carefully revised by W. D. Smith, Chief of the Division, and extended to the east and north.

The oil situation has not changed greatly. The Bahay Valley Oil Co. is drilling and one other company is about to begin but it is too early to report results.

LONDON

Oil Speculation Follows Rubber.—Anglo-Maikop.—Oran Oil Co.—Newfoundland Oilfields Co.—Trinidad Oilfields.

The London speculative market is at present absorbed in rubber-shares with oil as a good second, and large amounts of capital are being readily subscribed. The Commonwealth Oil Corporation has been before the public for some years and its fortunes have been unfavorable so far. This company owns property in New South Wales, 100 miles to the northwest of Sydney. The exploitation of the oil-shales proceeds slowly and the more recently discovered coal seams receive the greater share of attention. Another company owning shale lands in the same district has been floated recently, the Australian Oil Co. The Maikop district of the Caucasus is especially in fashion. It suddenly sprang into note last autumn, and already several companies have been floated successfully. This week the Maikop Midland Oilfields was introduced to the public. It has been formed as a subsidiary of the Anglo-Maikop Corporation. The Maikop district is situated toward the western end of the Caucasus about 50 miles from the port of Tuapse on the Black sea, and is at the opposite end of the Caucasus from Baku which is on the Caspian sea. Boverton Redwood and A. W. Eastlake have reported favorably on the properties acquired by the Maikop Midland and will act as technical advisers to the company. The capital is £157,500 divided into 150,000 ordinary shares of £1 each and 150,000 deferred shares of 1s. each. Of these shares, 100,000 ordinary and 20,000 of the deferred are offered for public subscription, the remainder going to the Russian owners together with £20,750 in cash, and to the Anglo-Maikop Corporation, which has guaranteed the success of the present issue. The Maikop Oil Proprietary is another of the recently formed companies. Paul Dvorkovitz, well known in connection with the Russian oil industry, is managing director and technical adviser. The capital is £252,500, divided into 250,000 ordinary shares of £1 each, and 50,000 deferred shares of 1s. each. Of these 125,000 ordinary and 12,500 deferred are offered for public subscription. The whole issue is underwritten by the promoters. The International Maikop is the third during the week. The properties acquired were selected by the representative of J. S. Bergheim, one of the board, and the prospective managing director. Mr. Bergheim is chairman of the Nigeria Bitumen Corporation. The capital of International Maikop is £83,000, divided into 320,000 ordinary shares of 5s. each and 60,000 deferred shares of 1s. each, of which 160,000 of the former are offered for public subscription. This issue has also been underwritten. The fourth company is the Maikop Premier Oil Syndicate. Thompson & Hunter are the engineers and the commercial part of the business is in the hands of Matheson & Co. The syndicate has a working capital of £19,000. The oil deposits in North Africa are represented in London by the promotion of the Oran Oil Co. which has been formed for the purpose of acquiring the petroleum lands and works in Algeria belonging to the French company Societe Anonyme des Mines de Petrole d' Ain-Zeft. This property is about 70 miles east of Oran and 15 miles from the Mediterranean coast, and is on the line of railway connecting Oran and Algiers. It has been worked so far in a small way only. There are eight wells, but only two are being pumped at present. A refinery has been built with a capacity not greater than 500 barrels of crude oil per month. Boverton Redwood, William Topley, and M. J. Stephan are all of opinion that with additional capital the output could be greatly increased and a profitable business established. The object of the present flotation is to raise the funds required. The capital of the new company is £175,000, of which £55,000 in shares is alloted to the promoters together with £30,000 in cash, while 120,000 shares are being offered for public subscription. The promoters pay £48,000 in shares and £24,000 in cash to the French vendor company, and they guarantee the subscription of 80,000 of the shares offered to the public. Newfoundland has supplied another investment in oil. The Newfoundland Oilfields Co. has been formed for the purpose of acquiring and developing oil-bearing land on the northwest coast of Newfoundland near Parsons Pond. The commercial agents for the sale of the products are Meade-King, Robinson & Co. oil merchants, Liverpool, one of the partners of which firm, William Smellie, is a director of the company. Boverton Redwood and J. D. Henry have reported on the property and made suggestions for its development. As far back as 1812, Mr. Parsons, who gave his name to the district, discovered the existence of oil in the locality, and a well was first sunk in 1867 by Mr. Silver of Halifax. Subsequently in 1895 the Newfoundland Oil Co. commenced drilling and provided some machinery. It is for the object of extending the operations thus begun that the present flotation has been undertaken. Mr. Henry estimates that £40,000 will be sufficient to put in order and equip six of the present wells and to drill six others, besides providing a power-house, a pipe-line, and storage tanks. The oil yields on refining, 18% benzine, 38 kerosene, and 41 of heavy oils and paraffin wax. The company starts with excellent

economic conditions, for the position on the sea coast gives easy communication to the world's markets, and the Government is providing a protective import duty. The capital of the company is £200,000, of which £77,400 in shares and £17,800 in cash is the purchase price, and £12,200 represents commissions and cost of forming the company. The 80,000 shares now offered to the public have been underwritten and 42,600 shares are held in reserve. The present flotation will provide £50,000 as working capital. The Trinidad Oilfields is the name of a company formed to acquire oil lands in the Guapo and La Brea districts of the Island of Trinidad. There are three wells in operation that 'struck oil' at depths of 712 ft., 672 ft., and 520 ft., respectively. The oil has an asphalt base and leaves little paraffin-wax residue, so that it is specially applicable as fuel. The deposits are close to the sea, and the oil will therefore be cheaply exported to the neighboring islands in the West Indies and to parts of South America. Reports on the property and on the oil produced have been made by Thompson & Hunter, and by Boverton Redwood. The prospectus of the company offers 175,000 shares of £1 each to the public. These have been underwritten at a commission of 6% together with a call on 40,000 shares. The vendors receive £85,000 in shares and £68,000 in cash. With the working capital obtained by this flotation, approximately £100,000, it will be possible to erect a plant that will produce 3000 tons per month at first, and 6000 tons within two years. The cost of producing will not be more than 15s. per ton and may easily be much less. The directorate is composed of sound business men.

NEW YORK

Copper Situation.—High Cost Producers Must Curtail.—Surplus, and Producers Assn. Figures. — Silver Market Improves. — Canadian Minerals.—Market Conditions.—Mason Valley.

The copper situation is an absorbing topic of interest. The underlying tone is optimistic, but the prevailing impression is that some time will be required to put the metal market in better position. It is evident that the high-cost copper producers must prepare for a period of lean and diminishing profits. In the present unorganized state of the industry curtailment by agreement is out of the question. The Calumet & Hecla, which recently cleaned up its unsold metal at 13c. and makes a satisfactory profit at that figure, would hardly agree to any policy of curtailment, though for some time this company has not been crowding production. The new low-cost porphyries, such as Utah and Nevada Con., could hardly curtail to any marked extent without cutting off their dividend payments, which have but just begun, and the shareholders who have struggled through the earlier years of development, would not endorse such a policy. Amalgamated Copper, with a large surplus and a low dividend rate, is prepared to worry through a lean period and can very calmly see its high-cost competitors go out of commission for the time being. It is plain that consumption is more difficult to tabulate than is production. It has been claimed that consumption was increasing and was overtaking the output, but, going back over the figures of the past fifteen months, or since January 1, 1909, it is seen that production is running about 10% ahead of consumption, a condition which the users of copper understand perfectly and do not propose to alleviate unless compelled to. The selling agencies state that the demand for wire bars used by power-transmission companies is hardly one-half what it should be, and this item alone if brought up to normal would turn the scale between producer and consumer. It is deferred business such as this which must come to market in time that gives the copper statisticians an optimistic tone in spite of the momentarily discouraging position. The annual report of Aron Hirsch & Sohn of Germany estimates 1909 world output at 834,940 tons, as against 746,585 tons in 1908; 702,044 tons in 1907; and 741,654 tons in 1906. The increase in the world's accumulated stocks during 1909 is estimated at 64,000 tons. The figures of H. R. Merton & Co., of London, for the year's production are 839,300 tons. Greene-Cananea is one of the high-cost coppers which is being forced to a policy of curtailment. The output for the quarter ended March 31 was 10,780,000 lb., as against 11,652,000 for the same period a year ago. Copper costs are about 10½c. per pound, on which basis the management prefers not to push production. Some of the old stockholders of the Greene Consolidated Copper Co. are again threatening litigation, claiming that there has been no proper accounting by the present management of the cash with which the Greene-Cananea started operations. The position of Granby is now well known, its copper costs admit of practically no profit on the present market. The Rio Tinto of Spain, the oldest and one of the most important copper mines of the world, is now working by the open-cut method and the magnitude of its operations is noteworthy. In 1909 twelve steam-shovels of the largest capacity, 50 locomotives, a thousand wagons, and several thousand men were employed in the removal of the overburden. Seven million tons of hard rock requiring drilling and blasting were removed. This is an engineering operation of greater magnitude than is involved in any one section of the Panama Canal work. Speaking of the metal situation, the chairman of the Rio Tinto board said at the recent annual meeting: "The future of the copper market rests entirely in the hands of the large American producers, and I am confident that consumption would in no way be harmed if moderately higher prices were obtained by the regulation of their output." The furnaces of the British Columbia Copper Co. smelter are being enlarged to admit of the handling of the ores from the New Dominion Copper Co. The contract is being arranged and work on the new basis is expected to begin shortly. So far as the public is concerned, the copper surplus and the postponement of any possible merger has worn out the enthusiasm prevailing for a year or longer and a new interest is being sought. The International S. & R. Co. is pressing its position in the smelting industry. The new Utah smelter, to be blown in by June 1, is expected to show such an increase in earnings as will permit of the dividend rate being advanced to 10% soon thereafter. In addition it is expected that an announcement will soon be made of plans for the erection of another smelter and refinery, in preparation for which, treasury stock will be issued and valuable rights offered to the stockholders. The Mines Company of America, operating the Creston and the Colorado mines, at Minas Prietas, Sonora, Mexico, earned $63,111 for the first quarter of 1910. Dividend requirements were $60,000, so that only a nominal amount was carried to surplus. In view of the declining earnings it is evident that unless some of the new territory now being prospected develops into producing ground the profit earning days of the Mines Company will soon terminate. The properties made a great deal of money for those who took them over when the present company was formed.

Smelter, Greenwood, British Columbia.

T. L. Livermore has announced his intention of resigning as the chairman of the Copper Producers' Association. It has been rumored that the Association itself would dissolve, on the theory that the monthly figures given out are being

used unfairly for speculative purposes. It is not believed that such a step will be taken, however, as the immediate conclusion would be that the copper surplus would become so burdensome that figures could no longer be given out. The public has been quick to grasp the value of the statistics gathered by the Association, and as they are by far the most valuable figures ever collected in the history of the copper industry, it is to be hoped they will not be discontinued. The basis for the somewhat mysterious recent decline in North Butte is shown in the annual report of the company, now in press. Ore reserves are figured at 822,200 tons of an average copper content of 4¼%, or 85 lb. of copper per ton; a total copper output of 69,887,000 lb. On a 13c. copper market, figuring costs at 9.78c., the average for 1909, the profit per pound would be 3.22c., or a total profit of $2,250,361, equal to $5.62 per share upon the company's capital of $400,000.

The situation in silver is fully as interesting as is the copper metal market. When the Indian Government recently placed an import duty of 5 to 15% upon all silver brought into India, it was anticipated that such action would greatly restrict the buying from that country, which is one of the heavy consumers of the white metal. Oddly enough the enactment seems to have stimulated buying. China, probably the largest user of silver in the world, has also been in the market. These demands, coupled with an announcement of the Canadian Government, that some 7,000,000 oz. of silver will be used in the coinage of new silver dollars, have combined to put the price of silver up to a higher level than has been reached for many months. Quotations at 53½c. have been recorded and further advances are hoped for. While Cobalt properties have been able to produce silver so cheaply as to make enormous profits even at low prices, each advance in price adds just so much to net earnings. The silver camps of Mexico will feel the stimulation of an advancing silver market much more keenly. The leading Guanajuato producers have long felt the need of more margin between gross returns and operating expenses. Every fractional advance in silver above the present market will insure something above the 'swapping of an old dollar for a new one' for Guanajuato, Zacatecas, and many other gold-silver camps of Mexico, whose large bodies of low-grade ore will be developed into big long-lived producers if conditions will but reasonably insure any profit commensurate with the size of the undertaking. The Nipissing Mines Co. shows in its annual report a production for the year 1909 4,646,877 oz. of silver, for which an average price of 51.547c. per ounce was realized. Costs, estimated per ounce, as copper costs are estimated per pound, were 16.39c. per ounce. Total profits were $1,644,869, of which the shareholders of the Nipissing Mines Co., the holding company, received $1,500,000 in dividends, the treasury retaining a surplus of $1,543,989. If, in addition to the tremendous earning power, on comparatively small investment, Cobalt could add the element demonstrated ore reserves, proving a definite era of production for its mines, the camp would be the wonder of the world. Nipissing figures ore in sight at 6,539,200 oz., or a life of some eighteen months at the present rate of production. The large territory of this company gives it a commanding position, and its known ore reserves are not to be taken as defining the property's productive limits, but the element of uncertainty has proved of enough weight to rob Cobalt of its public following. There is a renewal of the rumor of a large Cobalt consolidation, not denied by the representatives of the various companies supposed to be interested, the reply being that as yet there has been no attempt to work out any details.

Andrew Friedman and Julius A. Lewisohn have been added to the board of directors of the Miami Copper Company.

The total mineral output of Canada in 1909 was a little over $90,000,000, an increase of over $3,000,000. The silver output was 27,878,000 oz., valued at $14,358,310, of which nearly $13,000,000 was the output of Cobalt mines. The gold production amounted to $9,500,000, a slight decrease as compared with last year. The output of the Yukon district, however, was $3,960,000, which was an increase of $360,000. The Sudbury nickel deposits yielded 28,845 tons valued at $3,913,012. Pig iron amounted to 757,162 tons estimated at $9,581,955, being an increase of 20%. The coal output showed a slight decrease, being valued at $24,431,351.

The markets of the East have been featureless. The attack by the Government upon the participants in the cotton pool has counteracted in part the effect of the postponement of the decision in the Standard Oil and Tobacco Trust cases. The avowed intention of the Department of Justice to stop trading in futures is something of a facer for the speculators, who are now all up in arms proclaiming themselves as wholly legitimate and as engaged strictly in the merchandising of staples. A collapse of London's rubber boom is predicted almost hourly. Inasmuch as the demand for crude rubber is largely due to its use in automobile tires the financial paragraphers have become fixed in the habit of referring to the expected denouement as a 'puncture'. Seriously, however, the expected crash is an unsettling element.

It is reported here that the North Butte Co. has reached the Edith May vein by diamond-drill at a depth of 2800 ft., some 600 ft. below any of North Butte's present workings. The drilling was done from the Diamond shaft, and the core showed high-grade ore. The width of the vein is estimated at 45 ft. It is believed here that negotiations now under way for the absorption of the Clark properties at Butte, will be carried through. There is more stress being laid upon the apex controversies at Butte and the fact is that welding the properties into one ownership will eliminate all of these questions. The statement is made that the Amalgamated has existing disputes over vein ownerships with nearly every independent operating company in Butte, and there is no doubt that apex questions are responsible for the surprising action in leaving North Butte out of the consolidation.

The death of Thomas F. Walsh, the foundation of whose fortune was made in the Camp Bird mine at Ouray, Colorado, has called attention to that property and its enormous production. The Walsh estate is estimated at some $8,000,000 to $10,000,000, most of which was accumulated from mining ventures in Colorado. The British Columbia Copper Co. shows a net profit of $51,300 for March, as against $41,000 for February, the increase being partly due to lowered copper costs. British Columbia is improving in this regard, and must in the future be counted among the low-cost producers; March figures were 7.83c. per lb. for copper in New York; February costs were 7.88c. The fire at the mill of the Goldfield Consolidated had some adverse effect upon the reviving market in the Nevada stocks, but on the whole the disaster was viewed with greater philosophy than might be expected. The absorption of convertible bond issues put out by mining companies has made this a favorite method of financing. In many instances, the results have been most satisfactory, from both the standpoint of the purchaser and the company's treasury. The Mason Valley Mines Co. has added a new feature to its $1,000,000 bond issue just being offered to the public. The mortgage provides that the company is to pay annually to the trustee, as a sinking fund, 20c. for each dry ton of ore treated, the payments to be reduced proportionately as bonds are converted or redeemed. Some $400,000 of the proceeds of the bonds are to be used in the erection of a smelter of 800 tons daily capacity, which will handle the company's output and also do custom work. Joseph F. Schwab has been appointed receiver for the Mitchell Mining Co. This concern was at one time quite a bidder for market prominence in the East mostly through the efforts of George Mitchell, the promoter. The company's assets consisted of stock in the La Dicha Mining & Smelting Co., and the La Dicha & Pacific Railroad Co. Among mining engineers the La Dicha is a fund for a little reminiscence. When the property was first taken up by the Mitchell company one well known engineer reporting upon the ground which carries an orebody that is almost a blanket formation took his measurements for width on the dip of the vein with the result that gross value ran up to almost fabulous figures; an error of which the promoters were not slow to take advantage.

General Mining News

ALASKA

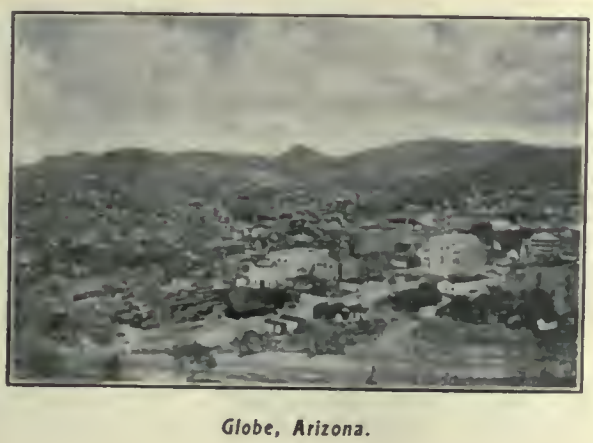
(Special Correspondence).—The Lon De Van Mining Co. has purchased the Sea Level compressor-plant and will install it on the company's property on Georges Inlet. The adit is now in 125 ft.——A 200-ft. shaft is being sunk at the Goodroe mine.——The Standard Alaska Co., at Thorn Arm, is opening a good body of copper ore.——The compressor-plant at the It mine is running full blast and several stopes are being worked on the 150-ft. level.——The Sulzer mine has added 14 men to its payroll.

Ketchikan, April 16.

ARIZONA

COCHISE COUNTY

The report of the Calumet & Arizona Mining Co., at Bisbee, for the year of 1909 has recently been mailed to the stockholders showing that the total receipts for the year amounted to $5,054,664. Dividends amounting to $800,000 were paid with a cash balance at the end of the year of $813,360. There were 27,630,050 lb. of copper produced at an average cost of 13.047c. per lb.——The California & Paradise Mining Co., operating the Leadville mine in the Paradise district, has completed the installation of a hoist, 30-hp. boiler, and No. 5 Cameron sinking pump. The shaft has been retimbered and development resumed.——The cross-cut on the 325-ft. level of the Centurion at Dragoon



Globe, Arizona.

has opened a body of copper carbonate and red oxide ore.——At Courtland the diamond-drill in the Mamie broke into the old workings which are gradually being drained.

GILA COUNTY

(Special Correspondence).—The first churn-drill on the Live Oak property is in good sulphide copper ore at the depth of 180 ft. This hole will form a surface connection with the drifts on the 300-ft. level of the mine.——Work underground at the Miami is still confined to blocking out the ore above the 420-ft. level, and preparing the haulage level for the electric haulage system. All construction work is to be completed within six months and production should be commenced by the first of the year.——Churn-drilling continues on the Cordova property with various results. The three holes drilled have shown the existence of sulphide assaying less than 2% copper. The work is carried on by the Hoyland & Smith interests, in conjunction with that at the Warrior and Live Oak properties.——The Warrior Development Co. is shipping the usual 100 tons per day of 10% ore. No sulphide ore has yet been mined at this property and very little has been cut by the churn-drill.——At the 660-ft. level the National Mining Exploration Co. has opened an 8-ft. fault of gossan material, containing considerable specular hematite and a small amount of copper.——The work at the Arizona Commercial property, for the next few months at least, will consist of development work on the lower levels of the mine. The smelter force and most of the miners have been discharged and a large part of the office force will be discharged May 1. The smelter has been shut down as the water on the eighth level has been too heavy for the pump to handle and the development has fallen behind.

Globe, April 22.

MOHAVE COUNTY

At Needles 100 men are at work rushing to completion the big concentrating mill of the United States Smelting, Refining & Mining Co. The machine shops and warehouses are already finished, as are also the foundations for the big mill proper and an elevator trestle. Shipments of ore are being received daily for the smelter, which has been repaired and which will probably blow in during May.——B. F. Keith, consulting engineer for the Tom Reed mine, in company with J. H. Hobbs, spent several days at the mine inspecting both mine and new mill. He was very much pleased with the orebodies being opened on the Tom Reed claim, about 1500 ft. west from the main working shaft, and also with the mill. He stated that the Tom Reed would probably resume paying dividends in May. Mr. Keith expects to return in several weeks to make an examination of the Ruth mine in the Silver Creek district.

PIMA COUNTY

The shaft of the Twin Buttes Mining & Smelting Co. is now down 700 ft. and drifts have been started on the orebody. A good grade of ore is being opened and the company is figuring on erecting a smelter.——Shrote & Alford, operating the Golden Eagle mines 65 miles west of Tucson, have ordered a mill which will be installed at an early date.

PINAL COUNTY

The cross-cut from the bottom of the 200-ft. incline shaft at the La Coronado mine, 18 miles north of Florence, cut an 8-ft. orebody. Drifts have been started on the vein and a good grade of copper ore is being opened. B. Reed is superintendent.

YUMA COUNTY

The cross-cut north on the third level of the Yuma Consolidated property has opened a 3-ft. orebody containing a fair percentage of chalcocite and chalcopyrite. The company discounted the payment on its bonds by paying $23,000 which was not due till June. This leaves only the final payment of $23,000 due.

CALIFORNIA

BUTTE COUNTY

The Western Gold Dredging Co. has been incorporated at Oroville to work a portion of the ground on Thompson's flat which it has secured under lease.——The machine shops of the Natomas Consolidated Dredging Co., at Thermalito, have been completed and all the machinery is now installed giving the company facilities for handling any of the repair work on the dredges.

CALAVERAS COUNTY

Owing to the scarcity of water at the Little Daisy, near Mountain Ranch, the mill is only being run a portion of the time though good clean-ups are reported.——The last clean-up at the Moosehead is reported to be the largest in the history of the mine. There is a fair supply of water in the ditch and piping will be continued for the next two or three months.——A body of rich ore has been opened in the Mount King mine of R. B. Parks, near Hodson.

INYO COUNTY

The Loretta copper mine east of Bishop is being reopened under the management of J. G. Kirchen. The main shaft is down 400 ft. in commercial ore and two adits have been driven to cross-cut the vein. The mine was shut down about a year ago owing to a dispute among the stockholders of whom Charles M. Schwab is the largest individual owner.

NEVADA COUNTY

It is reported that operations are to be resumed at the Pine Hill mine in the lower part of the county. A good grade of copper-gold ore has been opened but the property has been idle for some time on account of litigation. It is close to the line surveyed for the California Midland railway and could ship the ore or build a smelter at a favorable

location.——Excellent headway has been made at the Birchville mine near Granlteville since operations were resumed at the property. The mine has been unwatered and the 10-stamp mill running for the past three weeks. Water-power is being used now, but as soon as the snow melts wood will be hauled in and the boilers fired up.

SHASTA COUNTY

The cross-cut on the 1000-ft. level of the Reid mine, at Old Diggings, opened a 12-ft. vein and is being driven to intersect a smaller vein that is known to exist beyond the main one. This gives the company 400 additional feet of backs.——The Balaklala Copper Co. has almost completed the railroad from the sawmill to the mine, a distance of a mile and a half. The company is now working about 500 men.

SIERRA COUNTY

(Special Correspondence).—Los Angeles capitalists have acquired the Twenty-three and Joker claims at Alleghany. ——Reports of a strike among the Alleghany miners are without foundation.——The Standard has made a clean-up of 1700 lb. of ore and shipped about 140 lb. of bullion to the mint. The tailing has been sacked for shipment to the Selby smelter. The new owners of the mine contemplate the early installation of a small mill.——The Black Warrior quartz claim which adjoins the Standard on the north, has been taken under bond by Davis & Richardson, of Monterey.——The adit of the Forest Queen has broken through the lava into bedrock. It is expected to cut the channel shortly.——The California gravel mine has been taken under bond by Nevada capitalists.——The Four Hills has suspended operations until supplies can be brought in.—— The Penberthy has cut a shoot of rich ore at a depth of 20 ft. Clyde Penberthy is superintendent.——The Caesar Mining & Exploration Co. is working on a 4-ft. vein and expects to install an electric power-plant this summer.

Alleghany, April 25.

SISKIYOU COUNTY.

(Special Correspondence).—Chase & Hicks have leased the water of the Scott Bar Hydraulic Mining Co., and are operating three giants on the upper channel. Water is delivered under a pressure of 300 lb. Several $25 and $30 nuggets, in addition to considerable coarse gold, have been extracted. It is planned to extend the 17-mile ditch 7 miles farther to increase the flow.——A number of rich discoveries have been made recently by prospectors in Quartz valley.——The Mono mine is opening good ore and paying regular dividends. The mine is equipped with a 10-stamp mill, but only about 20 tons of ore are being handled per day. T. M. Newcomb, one of the chief owners of the New Idria quicksilver mine, is president.——The Hathaway Mining Co. has placed orders for a new plant of machinedy with a San Francisco firm. The new management is arranging for more aggressive work.——Operations will be resumed shortly at the Plow Boy.——Several properties in the Blue Ledge copper district are receiving attention, but the distance from transportation and lack of reduction facilities is handicapping work. It is again rumored that the Blue Ledge Copper Co. is considering the installation of a smelter.

Yreka, April 23.

TUOLUMNE COUNTY

(Special Correspondence).—It is expected that complete operations will be resumed at the Shawmut mine between May 1 and 15. A new hoist has been installed and other improvements made.——It is reported that operations will soon be resumed at the Contention mine, in the Knight's Creek district, with A. C. Morrison as manager.——W. E. Booker and L. L. Coper, who recently secured a lease on a part of the Jumper ground, near Stent, have begun driving an adit toward a supposedly rich shoot of ore, which they expect to reach before long.——The Over mine, on Bald mountain, operated by Hamilton & Davies, and in which several small pockets have been found during the past year, a few days ago yielded $500.——Preparations have been commenced for erecting a mill at the Tarantula mine. A compressor and machine-drills were recently installed and excellent progress is being made in the development of the property. T. B. Russell is manager.

Tuolumne, April 25.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—Construction work has been put under way by the Conqueror Mining & Milling Co. in the building of a boarding house, and grading started for the new 100-ton mill.——The new compressor plant at Marshall-Russell adit on Miller mountain was started up last week. Two Rand compressors with a capacity of five drills each have been installed. One is to be run with electric and the other with water-power. O. N. Marlhugh is manager.——From a shipment of one carload of dump matter from the Centennial mine to the Mizell mill at Idaho Springs, a saving of 45% was effected on the plates. The tailing gave 31%, making a total saving of 84%. David Kennedy, the manager, states that work on the new mill of 50 tons capacity will be started about May 1.——The United States Mining Co. has secured a five-year lease upon the Doves Nest group of eight claims on Bellevue mountain. A lateral is to be driven westward from the Newhouse tunnel, and as soon as the Central adit intersects the Bellman vein, another lateral is to be driven east to connect with the one being run from the Newhouse tunnel. The operating company purposes constructing a 500-ton mill to be built below the dumps of the Newhouse workings. H. B. Clifford, of New York, is manager.

Georgetown, April 23.

GILPIN COUNTY

(Special Correspondence).—A pool of miners has started work in the unwatering of the shaft on the Forks mine. The shaft is down 400 ft. and it is proposed to sink another 100 ft.——Sinking has been resumed on the Federal mine. ——The East Pewabic mine has been taken under bond and lease by the Gilpin-Hurricane Mining Co.——The Daisy mill in Gamble gulch has been started and the machinery is being fed ore from the Marine mine on Tip Top mountain.——The shaft on the Gold Flint mine has reached a depth of 400 ft. On the fourth level there is exposed a 12-in. streak of ore that mills $62 per ton in gold and silver.

Central City, April 22.

LAKE COUNTY

The installation of a 1200-gal. pump at the Wolftone shaft of the Western Mining Co. on Carbonate hill marks the commencement of a vigorous campaign to develop the lower horisons in that district. The Western Mining Co., which is controlled by the Guggenheim interests, owns or leases a group of claims, including the Maid and Henrietta groups. When these interests consolidated these different groups it had been demonstrated that the territory contained one of the largest sulphide deposits in the district. It had been traced continuously for more than 1000 ft. from the Maid and Henrietta to the Wolftone. For several years the company has kept a large zinc mill busy handling zinc sulphide. The installation of the large pump at the 1000-ft. level means that the company intends to carry on a more extensive system of development in the lower limestone, and the result will be increased shipments.——The early resumption of operations on the Long & Derry property by the Anona Mining Co. will mark a renewal of activity in a portion of the district which has been idle for the past year. Long & Derry hill was the scene of a gold excitement a few years ago, but as satisfactory results were not achieved there was a general cessation of operations.——A. E. Hanlfen, owner of the Louisville, is working the property through the Yak tunnel and taking out a considerable tonnage of sulphide ore. The Louisville is one of many properties which are being successfully worked through the big bore that now taps a region three miles long from California gulch almost to the Mosquito range.

OURAY COUNTY

The Wedge property, north of Ouray, was the centre of considerable excitement recently on account of a rich find made in the mine. About six inches of brittle silver was cut which will run up into the hundreds, if not thousands, of

ounces per ton. This streak is in addition to the large amount of ore already blocked in the mine, which will assay in the neighborhood of $200 per ton. The property is being worked under lease by F. M. Jackson and promises to be a bonanza for him.——The Wanakah Mining Co., operating the Bright Diamond mine, has purchased a new tram to be erected from the mine to the American Nettie mill, which it has under bond and lease. New mill machinery will be installed. The mill is under process of overhauling and will be equipped with machinery suitable for treatment of the ores. In putting in this tram it was decided to have it entirely new throughout. After the tram is in, a compressor plant will be installed. At present development is hindered by the fact that the ore being extracted has to be thrown away on account of lack of room to store it at the mine. The installation of the compressor plant means a relief in this particular and will enable the company to carry out its systematic plan of development. Arrangements have been made with the Colorado Smelter Co. to take care of the entire output of the property, concentrate as well as crude ore, and upon the early equipment of this property largely depends the blowing in of the smelter.

TELLER COUNTY

The orebody opened recently on the Trilby property on Bull hill is improving. The vein when opened showed a width of 1½ ft., but in being followed has widened and now measures more than 2¼ ft. between walls with no decrease in value. The ore is at a depth of 1300 ft., and the shoot, believed to be the extension of the vein exposed on the level above, gives assay returns of from 1 to 11 oz. gold per ton. The Trilby is one of the steady gold producers, and ore is shipped both by lessees and on company account.——Machinery for the Camilla mine on Guyot hill has been ordered and will be installed upon delivery by F. B. Goetz and Denver associates, who recently secured a four years' lease on the property from the owning corporation, the El Paso Extension Mining Co.——A small but rich seam of sylvanite has been opened in the old vein exposed in the Christmas property, situated on Bull hill and operated under lease by George Potvin.

IDAHO

BOISE COUNTY

(Special Correspondence).—Announcement is made at Idaho City, in Boise basin, that the Woodburn placer properties have been sold by H. L. Woodburn to Charles Herrick, of Loraine, Ohio, for $125,000. The properties include the East Hill and Gold Hill groups, formerly operated by K. P. Plowman, which have been worked by Mr. Woodman during the last ten years. These placer holdings include 45 miles of ditches and flumes by which water for hydraulic work is delivered from More and Elk creeks.

Boise, April 23.

SHOSHONE COUNTY.

Machinery for the reduction of the tungsten and gold ores of the Golden Winnie property at Murray will be purchased at once. E. M. Smith, president of the company, has gone to Denver and Eastern points to place orders for a concentrator, Card table, rock crusher, and rolls. The new flume and ditch which carry the water to the mill-site have been completed. Sufficient ore has been blocked out to keep the reduction plant running for two years. The ore contains about 35% in tungsten and $18 in gold per ton. The Golden Winnie has been worked as a gold property since its discovery 18 years ago. It was learned only a year ago that large quantities of tungsten ore had been thrown away in the search for gold.——The management of the Capitol Mining Co. announces that a contract for 250 ft. of work has been completed at the Capitol mine in the Osburn district, the job having been started in November. The company has stopped work until after the annual meeting in July, at which time it is understood the purchase of machinery will be decided on and a compressor and other equipment added so that development can proceed more rapidly. The lower adit is in 300 ft. and will be driven 800 ft. more. When the vein is reached at a point under the orebody found in the upper levels a depth of 800 ft. will be available. The company has expended more than $30,000 on its work.——Galena ore has been cut on the Rosander group of claims, adjoining the Idaho Northern group in the Murray district. The claims are within three miles of the railroad, with which they are connected by a good wagon-road and are traversed by three veins which have been prospected by more than 300 ft. of development work.

MONTANA

BROADWATER COUNTY

The introduction of new capital has created an interest in the Radersburg district, and the opening of some of the more prominent properties on an extensive scale promises to bring that district into public notice as one of the greatest gold-producing portions of the State and possibly in the West. The three most prominent properties at the present time are those being operated by the Keating Gold Mining, the Ohio-Keating, and the Black Friday companies, all of which are being equipped with electrically driven machinery for developing the ground at depth. The only handicap to the district at the present time is the lack of railroad facilities, the ore being hauled in wagons a distance of from 12 to 18 miles in order to be shipped to the smelters. Several proposals for the building of a railroad, to connect with the Northern Pacific railroad, probably at Toston, are being considered, and it is highly probable that the road to the Radersburg mines will be built during the coming summer or fall. This will greatly decrease the cost of handling ores and add materially to the profits of the mining companies.

NEVADA

ESMERALDA COUNTY

The Precious Metals lease on the Atlanta has, at a depth of 730 ft., reached the St. Ives vein, 370 ft. from the shaft. Some days ago a vein of promising looking quartz, alunite, and kaolinite was cut through, but this was not believed to be the main vein that was being looked for. The belief proved correct, and a few days ago the hanging wall of the main St. Ives vein was penetrated. A drift along the hanging wall, stripping the vein on that side, was run for some feet, and now a cut is being sent through the vein at two points, 40 ft. apart. From these drifts will be run to thoroughly explore the low-grade shoot that the vein proves to be at a point of exposure. The foot-wall has not been reached, although development has entered the vein for more than 20 ft.——Seventy stamps are steadily dropping in the Goldfield Consolidated mill, the temporary tramway from the railroad and crusher bins to the stamp-bins in the mill easily handling the 550 to 600 tons of ore per day that is being treated. In the meantime a big force of men is kept busy on the work of reconstruction, and as rapidly as equipment and supplies are received, everything is in readiness for them. The mill is steadily handling 70% of its full capacity, and at the same time reconstruction is being rushed as rapidly as is possible consistent with good work. In the meantime enough ore is being shipped to smelters to make up the 30% of the regular capacity of the mill, that is stopped because of the fire. The company is preparing a statement of the fire for the stockholders and will soon give out the date for the completion of the repairs.

NYE COUNTY

(Special Correspondence).—The Tonopah Extension management has decided to install coarser screens on the batteries and place the second tube-mill in operation. The sinking of the shaft on the Combination claim, 1500 ft. east of the main workings of the Round Mountain Mining Co. is well under way. The shaft has attained a depth of 20 ft. and will be sent to the 200-ft. level before lateral work is commenced. A hoisting plant is being installed. In the main workings of the company a winze is being sunk from the 800 to the 900-ft. level, 1000 ft. west of the shaft. The mill is running on ore from the Los Gabo and Great Western veins and is handling 120 tons of ore per day.——The Fairview is developing good ore in the west portion of the property. The main vein is 7 ft. wide with the ore averaging $12 to $15 per ton. Four raises are being driven to open

shoots exposed in the adit lateral workings. The mill is running steadily on ore extracted in course of development.——The Shoshone mill will soon be operating at full capacity, sufficient ore being guaranteed by lessees to keep the plant in operation.——It is expected to resume operations on the Sassy Sal lease on the Blue Jacket within a few weeks.——Edward Double, of Los Angeles, has made the final payment on the Allison placers on the main gulch at Manhattan and has started a force of men at work under Patrick Hollin. Mr. Double has also taken a lease on the placers of Top Knob No. 2 and is interested in the Four Leaf, operating below Central.——T. A. Johnson, manager of the Johnnie mine, states that the March production of the mill exceeded $14,000, and that the April clean-up will exceed this. The company is contemplating the installation of electric power and the enlargement of the mill. Excellent ore is being developed.——Jim Butler lessees are maintaining steady shipments of ore assaying over $30 per ton.

Tonopah, April 22.

OREGON

BAKER COUNTY

In the Susanville district at the present time the Gold Bug mine which is being developed by W. H. Turner, of Spokane, is probably the most active. A short time since the shaft was completed from the 200 to the 300-ft. level and a drift driven on the vein from the station 100 ft., at which point a winze has been sunk 50 ft. In the winze there is 2 ft. of ore that will average $75 per ton. Assays taken from the ore run from $30 to as high as $480. A new hoist is to be installed and the winze sunk another 100 ft.——One ton of ore from the Mammoth mine has been shipped to the Tacoma smelter for a trial run.——Operations are to be resumed at the Zenith mine.——Over 3000 sacks of shipping ore is reported to be ready at the Highland mine on Rock creek north of Sumpter and shipping will commence the early part of May.

SOUTH DAKOTA

LAWRENCE COUNTY

Denver parties, headed by W. G. Evans, of the Denver Tramway Co., have given to Stearns-Roger Manufacturing Co. the contract to construct a gold dredge at a cost of $100,000, to be operated at Mystic, a station on the Burlington railway, south of Lead.

TEXAS

BREWSTER COUNTY

Considerable ore has been shipped recently by the Boquillas company from Marathon on the Southern Pacific. This ore is hauled to the shipping point from the crossing of the Rio Grande at Boquillas, 90 miles distant. The mine is situated on the Mexico side of the river and is carried to this side by means of an aerial tramway. Traction engines are used to haul the ore wagons to and from the railroad shipping point.

UTAH

JUAB COUNTY

The station for the new pumping plant at the Centennial Eureka is nearly completed and will be ready for the machinery as soon as the pumps are forwarded to the mine. As soon as these are started the usual tonnage will be mined and 300 men employed.——The Raymond-Illinois property has been closed down temporarily on account of the heavy flow of surface water. This interrupts the work in the spring for about 60 days and it is presumed that operations will be resumed at the end of that time.——At the Eagle & Blue Bell the orebody has been opened 220 ft. above and 200 ft. below the 1000-ft. level, and the company is now preparing to open a new shaft by sinking from the surface and raising from the 1000-ft. level.

SALT LAKE COUNTY

Actual construction work has begun on the 18-mile railroad to be built by the Utah Copper interests from its mammoth Bingham mines to the Garfield concentrators and smelter, and the intention is to have the work completed and freight trains running between those two points within the year. The Utah Construction Co. has secured the contract for the grade work, which in Bingham canyon is extremely heavy. There are fills requiring from 30,000 to 70,000 cu. yd. of earth, and tunnels of 650 to 600 ft. One bridge will be 220 ft. high. The longest bridge will be close to the town of Bingham. Taylor Brothers have already started work on their sub-contract near the mouth of the canyon; E. M. Boyer and associates of Springville are making preparations to commence work immediately on their tunnel contract, and before the end of May it is

Eastern Nevada and Southern Utah.

thought that not less than 2000 men will be engaged on the work. A reservoir to contain 100,000 to 150,000 gal. of water to supply the various gangs along the line of work is now being built on a bluff above Lead Mine station, the headquarters of the Utah Construction Co. A 10-mile pipeline will convey the water from the canyon to the reservoir and there will be a system of laterals sending the water to the camps below.

WASHINGTON

STEVENS COUNTY

(Special Correspondence).—J. W. and E. C. Fryett, W. Townsend, and E. J. Cheatham have filed articles of incorporation, to operate under the title of the Buckskin Gold Mining Co.; capital $1,000,000.——The shaft on the west slope of Hungary hill, on the Factor group, is down 75 ft., where a station is being cut for the purpose of cross-cutting to the vein. Ore was found 20 ft. below the surface which assayed about $12 per ton. An adit, in 155 ft., is to be extended to intersect the vein.——On the North Star mine an adit is in 170 ft. A winze has been sunk, 20 ft. in from the portal, to a depth of 50 ft., following a stringer of ore which has increased from 18 in. to 6 ft. in width, at a depth of 150 ft. below the surface. The ore assays as high as an ounce of gold per ton, and a general sample $9.85 per ton.——In the First Thought mine the diamond-drill has revealed a new shoot of ore 140 ft. from the bottom level, in an opposite direction from a diamond-drill discovery of $600 ore, the latter about 500 ft. distant from the main workings.

Orient, April 23.

BRITISH GUIANA

The 10-stamp mill of the Aremu Mining Co. at Aremu commenced operations March 1. The shoot in the mine has been opened for over 200 ft. on two levels and assays from $15 to $20 per ton. The machinery at the mine consists of a central electric plant which furnishes power for the hoist, crusher, and mill, three 84-hp. Worthington boilers, and 120-hp. Mackintosh & Seymour engines direct connected to two 75-kw. Bullock generators. About 11 cords of wood per day are used which costs $2.50 per cord laid down at the mine. The land of the company is suitable for rubber production and the management has had the ground planted to rubber trees as it was cleared for fuel.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

COAL OR MINERAL LANDS.

Lands containing coal are held to be 'mineral lands' within the meaning of that term as generally employed in the laws regulating the disposition of the public domain. And it has been the general policy of the Government to reserve mineral lands from grants of the public lands.

United States *v.* Northern Pac. R. Co., 170 Fed. 498, Apr. '09.

LOCATION OF MINING CLAIM—ENTRY ON OPEN LANDS.

An entry under the mining laws was not invalid because the person entering the same had been upon the land before it was opened to entry and had remained thereon or in close proximity thereto during the expiration of the period fixed by the act of congress until after 60 days from the time the lands were opened to entry.

LeClair *v.* Hawley, (Wyo.) 102 Pac. 853, July '09.

EASEMENT IN CONNECTION WITH MINING CLAIM.

A conveyance to a mining company owning claims of the perpetual right to use adjoining tracts of land for a shaft and for dumping grounds, was held to be an easement, and that the improvements placed thereon in the working of the claims, together with the tracts of land constituted appurtenances to the mine and claims.

Park City Meat Co. *v.* Silver Min. Co., (Utah) 103 Pac. 254, June '09.

MINING LOCATIONS—ADVERSE CLAIMS.

The United States statutes which provide for the prosecution of adverse claims to mining locations, are said to apply only to adverse claims arising out of independent or conflicting locations of the same ground; they do not apply to controversies between co-owners claiming under the same location.

Allen *v.* Blanche Gold Min. Co., (Colo.) 102 Pac. 1072, July '09.

LEASE OF MINES—RECOVERY FOR EXPENDITURES.

In action for damages for breach of contract to sub-lease lands for mining on the contingency that the sub-lessees found paying ore, they were held entitled to recover for expenditures made in endeavoring to find such paying ores, though their prospective profits would be too uncertain and speculative as a basis for recovery. The measure of damages in such a case was said to be the actual expenditures incurred in the exercise of their work.

Ragland *v.* Conqueror Zinc Co., (Mo.) 118 Southwest. 1194, May '09.

INJURY TO MINER—PROOF OF NEGLIGENCE.

In an action for the death of a miner alleged to be caused by the negligence of the mine owner and operator, it was held proper to prove that the injury was caused by an overhead blast fired by an independent contractor, in order to show that the injury was not the result of the negligence of the mine operator. A court cannot be required, in such a case, to compel a witness to state whether a third person had discharged his duties to his own employees.

Travis *v.* Sloss-Sheffield Steel & Iron Co., (Ala.) 50 So. 108, June '09.

OIL WELLS—LIABILITY OF OWNER FOR POLLUTION OF STREAM.

The owner of an oil well is not liable for injuries to real estate bordering on a stream, the waters of which were polluted with oil and salt water, where such pollution was necessary to the enjoyment of the well, and where it was shown that the owner of the well had exercised due care to avoid the injury and was not actuated by malice. The question for the jury to determine was whether the owner of the well had made a reasonable use of it and had exercised diligence to prevent the injury.

Ohio Oil Co. *v.* Westfall, (Ind.) 88 Northeast. 354, May '09.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. H. CHANNING is in San Francisco.

FRANK H. PROBERT is at Bisbee, Arizona.

GEORGE H. GARREY is at Tonopah, Nevada.

JAMES DOUGLAS has returned to New York.

J. MORGAN CLEMENTS was in San Francisco.

W. H. WEED has gone to Kingman, Arizona.

COURTENAY DE KALB is at Douglas, Arizona.

L. D. RICKETTS has gone to Morenci, Arizona.

CHARLES JANIN has returned to San Francisco.

OSCAR H. HERSHEY was in San Francisco this week.

R. H. SARGENT is lecturing at Northwestern University.

J. H. WINWOOD has returned to Salt Lake from southern Utah.

U. S. GRANT lectured on 'Some Alaskan Glaciers' at Chicago recently.

DESAIX B. MYERS has moved his office to 321 Story Building, Los Angeles.

H. S. IMLAW is now superintendent of the Highland Boy mine, Bingham Canyon, Utah.

C. S. HERZIG, of the Constant-Herzig Co., is examining a mining property in West Virginia.

ROBERT H. RICHARDS has just returned from a professional trip to Virginia and to New York City.

M. R. RICHARDSON is now chief chemist for the Mazapil Copper Co., Concepcion del Oro, Mexico.

W. J. ADAMS has been ill with typhoid, but is now convalescent at his home in San Francisco.

R. Y. HANLON is in San Francisco. He will return to Korea, sailing on the *Chiyo Maru* May 3.

A. A. HAMERSCHLAG delivered the Commencement Day address at the Michigan College of Mines, April 22.

LEE FRASER has left the Aguacate Mines Co. to become engineer for the Abaugarez Goldfields of Costa Rica.

J. E. SPURR, of Spurr & Cox, Inc., has been appointed consulting geological engineer to Camp Bird, Limited.

EDMUND D. LACHMAN, stores manager for the Dolores Mines Co., Madera, Chihuahua, is in San Francisco on his way to the mine.

BERNARD MACDONALD will go to Parral shortly. He is designing a mill and cyanide plant for the Veta Colorada M. & S. Co., at that place.

W. R. JEWELL, formerly mineral expert with the Department of the Interior, has resigned and will open offices at Bakersfield, California, to examine and report on oil properties.

R. H. CHAPMAN, who is organizing topographic work for the Canadian Geological Survey, will be at work in the Selkirks and Kootenay district in May. His address for the summer will be Victoria, British Columbia.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

J. K., Korea: No. 1, chrysocolla; No. 2, massive magnetite.

J. H., Austin, Nevada: No. 1, fine grained diorite; No. 2, syenite.

R. V., Prescott, Arizona: Altered feldspathic rock with talcose inclusions.

O. B. A., Whitehills, Arizona: No. 1, chloritic quartzite with small cubes of pyrite; No. 2, kaolinized light granite; No. 3, gneiss with magnetite; No. 4, hornblende-chlorite

schist; No. 6, hornblende-chlorite schist; No. 7, porphyrite; No. 9, diorite.

J. C. H., Quartz, Montana: Micaceous hematite. Value depends on size of deposit, purity, and shipping facilities.

A. E., Sulphur, Nevada: Breccia coated with hornsilver and some embolite.

PUBLICATIONS RECEIVED

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

ECONOMIC GEOLOGY OF THE FELDSPAR DEPOSITS OF THE UNITED STATES. By E. S. Bastin. U. S. Geol. Surv., Bull. 420. Pp. 85, ill., index, maps. Washington, 1910.

The principal feldspar quarries in the United States are in New England and the Middle Atlantic States, and the annual value of the product is now about half a million dollars. Mr. Bastin discusses the chemical and physical character of the feldspars, their geologic occurrence and origin, and the methods of mining and milling, and describes in detail the deposits worked at the numerous quarries.

MEASUREMENT OF PULP AND TAILING. By W. J. Sharwood. Pamplet. Pp. 22, ill. London, 1910. The Mining Magazine. Price 50 cents.

The interesting and instructive articles published by Mr. Sharwood in The Mining Magazine has been published in a little pamphlet that every millman will want to have at hand. The conversion tables and detailed statement of methods will be of daily use.

BITUMINOUS OR OIL-SHALES OF NEW BRUNSWICK AND NOVA SCOTIA, ALSO ON THE OIL-SHALE INDUSTRY OF SCOTLAND. By R. W. Ells. Canada, Dept. Mines, No. 55 and 1107. Pp. 73, ill. Ottawa, 1910.

A report prepared under the joint auspices of the Geological Survey and the Mines Branch and discussing both the geology and economics of the subject.

ANALYSES OF ROCKS AND MINERALS. By F. W. Clarke. U. S. Geol. Surv., Bull 419. Pp. 323. Washington, 1910.

This is a tabulation of all analyses made in the Survey laboratory from 1880 to 1908. In the introduction Mr. Clarke has given new figures of the average composition of rocks.

OLD GRANITES OF THE TRANSVAAL, AND SOUTH AND CENTRAL AFRICA. By C. B. Horwood and A. Wade. Pamphlet, reprint from the Geological Magazine, Oct.-Dec. 1909.

COMMERCIAL PARAGRAPHS

The CONSTANT-HERZIG Co. is about to undertake examinations of properties in Utah and Nevada on behalf of London clients.

T. H. PROSKE, Denver, recently shipped two 15-ft. D 24 Ajax drill sharpeners to George W. Jackson, Inc., for use on the New York aqueduct at Yonkers, New York.

The AMERICAN STEEL CASTING Co. succeeds to the business of the Pacific Jupiter Steel Co., of San Francisco. The offices of the new concern is in the Sheldon building.

The Utah and western Wyoming interests of the PNEUMELECTRIC MACHINE Co., of Syracuse, New York, manufacturers of the Pneumelectric coal puncher, have been placed in the hands of the Utah Engineering & Machinery Co., 523 New House building, Salt Lake, Utah.

Myron G. Doll, for several years connected with the Denver office of the SULLIVAN MACHINERY Co., is now local manager for the company at Salt Lake, with offices in the Dooley building. He succeeds Matt. Brodie, who takes a position in the department of foreign sales.

THE CANTON BOILER & ENGINEERING Co., Canton, Ohio, has recently completed an order for ten 60-ton ladles for the Cambria Steel Co., Johnstown, Pennsylvania. This makes seventeen 60-ton ladles that this company has built this year, in addition to a large number of 20, 30, and 40-ton ladles.

RALPH ARNOLD and C. A. FISHER have opened an office in the Ideal building, Denver, and will undertake especially the examination of oil, coal, and other non-metalliferous deposits and underground water in the Western States. Mr. Arnold will continue his individual work in the California oilfields, making headquarters at Los Angeles.

EDITORIAL.

RIO TINTO, undoubtedly the greatest single copper mine now producing, worked last year on ores having an average copper content of only 2.349 per cent. A little over a million and three quarters tons of ore were produced.

NORTH BUTTE, it is announced, will hereafter issue quarterly reports. The annual report recently issued was excellent in character, and evidently the policy of secrecy which has provoked so much unfavorable comment is to be abandoned.

FAIRBANKS people have been watching the Haiditarod district anxiously this winter. Good reports have come back to the Tanana city, and at last reports eight steamboats were drawn up loaded and ready to start down the river with the first breaking of the ice.

FIRE-PROOF construction in and around mines is rarely possible. The most important places may, however, be safeguarded. The recent fire at Goldfield has brought out a point in favor of the zinc-dust precipitation process, in that the presses and their contents were found uninjured even though two of them had been hot enough to volatilize some of the zinc. It is customary to store the gold in a safe after precipitation, but in this case is was stored during precipitation.

OPINIONS of those in close touch with the copper market are that the publication of monthly figures of production and consumption of copper have a disturbing effect, and therefore the issuance of such information may shortly be discontinued. Unquestionably one result has been to develop spasmodic features in the market. Buyers of metal and traders in stocks suspend activity as the date of publication approaches, and feverish speculation has resulted in an effort to buy and sell in accordance with prevailing interpretations of the facts presented. There is in truth a lack of sufficient detail in the monthly statement, which results in throwing only a half-light upon the situation. The sources of consumption still remain unrevealed. Until more can be determined and given to the public on this side of the matter a fundamental factor needed to forecast the demand is absent; it only changes the point in the game at which some one has to guess what cards the others hold and then to boldly bid for making trumps. To suppress publication would seem to be a step backward. The better thing would be to give additional information. The spirits of evil walk in darkness, and the copper market is too

deep a mystery with the light available today to stand deliberate protection of manipulations that can be done only in the shadow.

Reclamation and Army Engineers

A tentative suggestion comes from Washington to the effect that the President plans to detail an Army engineer as Director of the Reclamation Service in place of Mr. F. H. Newell. Whether this is determined or is merely a toy balloon sent up to attract sharp-shooters, is uncertain. Unfortunately there is reason to suspect that the project is serious. When Mr. R. A. Ballinger was made Secretary of the Interior it was widely published as coming from him that he would 'get' the Reclamation Service, and it has been an open secret that there has not been that harmony between the Secretary and the officers of the Service that under the previous Administration did so much to promote the efficiency of that great Bureau. Civil engineers have been especially proud of the record made by Mr. Newell and his associates. They have demonstrated that it is possible under conditions of Government service, to build great engineering works honestly and efficiently. The Army engineers, frankly, have been jealous of any movement to place construction of public works in the hands of civilians. The officers of the Corps of Engineers are excellent routine administrators, as would be expected from their training. They are men of high character, and with their system of retiring allowances, which are denied to civilian employees, it is possible to keep them in the service. Fewer men resign to enter private practice than in other branches. All this may be frankly admitted without conceding that they should be placed in charge of all engineering work. In practice they have not proved to be especially brilliant engineers, and the bulk of their work is done by civil engineers employed by them, but denied high rank and pay. The original reason for giving them charge of public works, that they might be profitably employed in times of peace acquiring experience, broke down when during the Spanish War so few were transferred to active service. The Army has its own work and its men should be kept at that. There is no more reason why Army engineers should build irrigation canals than for them to have charge of the post-offices.

Appoint a Trained Man

The bill providing for a Federal Bureau of Mines has passed the Senate and, having been already approved by the House, will now go to conference for consideration of the amendments. It is believed that there will be few difficulties in reaching an agreement and that the bill will soon become a law. Thus ends a long campaign for legislation, and begins another of administration. Among the amendments proposed by the Senate the best was one changing the name of the proposed head of the Bureau from Commissioner to Director and raising the salary from $5000 to $6000. In giving the new officer the same title and salary as the Director of the Geological Survey, in placing the Bureau in the Department of the Interior, and in transferring to it the Technological Division of the Survey, Congress has indicated in a significant manner the wish that the new Bureau shall work in harmony with the Survey and be as like to it as possible. In this Congress has interpreted correctly the best thought of mining men, and we hope that the President will keep this in mind when he appoints the new Director. It is provided that this officer "shall be thoroughly equipped for the duties of said office by technical education and experience." We hope this provision will be observed both in letter and spirit. The high standing of the Geological Survey has come mainly from the fine spirit of the men belonging to it and the character of subordinates in any organization is influenced if not determined by the men at the head.

It is too early to even guess who may be appointed. Mr. John Hays Hammond naturally comes to mind, since, according to frequent press dispatches, he is the one mining engineer who is among the President's familiar friends. We doubt if the place would appeal to Mr. Hammond, as he would need to work as a subordinate to the Secretary of the Interior and would be the junior member of a large official family. If a Department instead of a Bureau had been created, and a position in the Cabinet were under consideration, it might well be another story. Aside, however, from Mr. Hammond's wishes, of which we believe he has given no indication, there would doubtless be objection to him urged by certain interests which will properly be considered. The movement for a Bureau of Mines originated in the West, but it was the coal miners and operators who finally won the battle; and the work transferred to it from the Survey relates to coal mining almost exclusively. Under the circumstances it is natural and right that the first Director, at least, be one thoroughly in touch with the problems of coal mining. Mr. Hammond's experience in that direction we believe is limited largely to his connection with the Stone Cañon mines. His large business interests might well prevent his being more than a nominal chief, and his relations with that intangible group known as 'Wall Street' would antagonize labor leaders who are vitally interested in the new Bureau. Mr. Hammond is a brilliant executive and has rare judgment in selecting assistants and in handling men. He has shown his repeated interest in the work of this Bureau, but we doubt both his interest in the appointment and the advisability of its being offered to him.

When one turns to others there are so many who might fill the place with distinction that choice would be difficult. If the President is wise he will, we think, appoint one of the officers of the Geological Survey already in touch with the work and familiar at once with its needs and the methods of Government administration. The obvious man is Mr. J. A. Holmes, the present Chief of the Technological Division of the Geological Survey, which will constitute the nucleus of the new Bureau. By training, experience, and ability he is excellently qualified, and his rare devotion to the work is well known. It would be a fitting appointment; but the essential thing after all is that a trained man be put in the place. To the new Director, whoever he may be,

we offer in advance our good wishes and our hearty support. The MINING AND SCIENTIFIC PRESS has favored the creation of such a Bureau for many years, and we take pleasure in at last seeing the starting of a work that we believe capable of great benefit to the whole mining industry, from the man with the pick, up the shaft through the offices of superintendent and engineer, to the counting room of the operator, and so out to the great general public.

Coal-Land Prices Again

In our Discussion department, Mr. L. K. Armstrong, whose thorough knowledge of mining conditions in the Northwest enables him to speak with especial authority, takes exception to our position with reference to the new prices now being asked by the United States Government for its coal lands. The subject is a large one and worthy of close attention. We are glad to publish Mr. Armstrong's letter though we remain unconvinced. We do not care at this time to argue further regarding certain of the questions raised, including that regarding the legality of a possible leasing system. We do not believe that such a system can be summarily dismissed as unconstitutional. Certainly the matter has been discussed at Washington among excellent lawyers without the objections raised being considered insuperable. It is interesting to note, however, that in his testimony before the Committee to Investigate the Interior Department, Mr. George Otis Smith, Director of the Geological Survey, urged the higher pricing of the land as a means of avoiding the necessity for a leasing system; a suggestion which seemed to appeal forcibly to several members of the Commitee. The argument is very simple: Fix the price of the land too high to make it profitable to hold for speculation, but not too high to permit operation, and then sell in reasonable units to any one desiring to purchase. This, it is urged, will automatically reserve to each generation the solution of its own problems without preventing present development. In one minor matter Mr. Armstrong is mistaken as to the facts. The new prices are now in effect, so far as coal lands have been classified and are for sale in the United States, and coal lands have been sold and are being sold at the new prices. The law simply fixes a minimum price and imposes no maximum. For many years the lands were sold at the minimum, but beginning when Mr. Garfield was Secretary of the Interior and continuing under Mr. Ballinger, they have been sold at prices fixed after an examination of each forty-acre tract. One thing more we would like to emphasize, and that is that to Mr. Roosevelt, on whose order the system was changed, the amount of the increase was considered unimportant so long as the rights of the United States, representing the people as a whole, were preserved. This, we believe, is the correct position. Measured against the total reserve, the amount of coal needed for present development is small, both in the United States and Alaska, and might be freely given, if need be, to anyone prepared to put the coal on the market. What is important is to keep the way open to save to society as a whole the 'unearned increment' on the lands not yet needed for development, and there is no way to do this so easy and so sure as by retaining ownership.

Minister Enrique Creel

Despite the growing magnitude of foreign investment in Mexico, critics of the Republic, friendly and unfriendly, are accustomed to ask, "after Diaz, what?" Great financiers are unlikely to err in their judgment of the stability of the Government, and their opinion is reflected in the market quotations of its bonds. Measured by this standard the conclusion is inevitable that the men whose business it is to make banker's profit out of national securities take no gloomy view of the outlook in Mexico. Evidently they are not disturbed by the further query, which no man can certainly answer, "after Diaz, who?"

President Diaz is ceaselessly building; his constructive faculty in government is constantly in evidence, and his policy is one of progressive conservatism. The presence of Señores José Yves Limantour, Olegario Molina, and Justino Fernandez in the cabinet, has long been a guarantee of stable and honorable administration of public affairs, and it has been appreciated within and without the Republic. The recent death of Señor Ignacio Mariscal, secretary of foreign affairs, created a vacancy which has just been filled by the appointment of Señor Enrique Creel. This must give universal satisfaction, as it is a further guarantee that the engine of state will not race to destruction when the time comes for changing the governor. Señor Creel is one of the ablest men in Mexico, a shrewd resourceful financier, who has built a goodly inheritance into a vast fortune by the methods common to financiers, but without blemish of 'graft'. He has been active in the mining and railroad development of the country for twenty years. He has been a powerful factor in the development of the fiscal and railroad policy of Mexico, which has stood the test through years of financial peril that sorely tried the soundness of the structure. He has won distinction in the diplomatic service as ambassador from Mexico to the Government at Washington. Señor Creel is a business man and a statesman. He is beyond doubt one of the most forceful characters the country has produced, and his elevation to the cabinet means that another dominant influence making for peace and progress has been added, which will aid any future president to maintain a course commanding the respect and confidence of the Nation and the World. The possibility of his succession to the presidency is precluded by the Mexican Constitution, which requires that the chief magistrate shall be the son of Mexican parents. Señor Creel's mother was native to the soil, but his father was an American citizen, formerly United States Consul at Chihuahua. Thus he is disqualified in a similar manner to Señor Limantour, whose father was a Frenchman. But, as ministers entrusted with important portfolios, these men will preserve the traditions of the Diaz régime, and will continue the policies that have been leading so rapidly to the expansion of Mexican industry.

Cost of Dredging in Russia and Siberia

Translated for the MINING AND SCIENTIFIC PRESS
By W. H. SHOCKLEY

The following costs are from a report of the Commission of Engineers,[1] organized by the Permanent Consulting Bureau of Gold and Platinum Producers on the 'Utility of Dredges in Russia', published in *Gold and Platinum*, June 15, 1909. In the tables the ruble is taken at 50 cents American for ease of calculation; the exact value is $0.514567.

Classification of expenses.[4]	In the Ural. Summer period,[2] seven months.	In the Ural. Winter period,[3] five months...	In the Ural. Yearly total....	In the Yenisei. Summer period,[2] seven months.	In the Yenisei. Winter period,[3] five months...	In the Yenisei. Yearly total....
I. Prospecting[5] ...	...	...	$350	...	...	$500
Total	..	....	$350	....	....	$500
II. Preparatory work:[6]						
Cleaning claims.	...	...	500	...	...	750
Clearing basin of ice for the spring work of the dredge...	...	...	150	...	...	200
Building side canals[7]	...	...	...	...	...	100
Making roads for transport of wood	...	...	75	...	...	100
Furnishing clear water for boilers[8]	...	...	50	...	...	100
Making small dams and sluices[9]	...	...	50	...	...	100
Transport temporary blacksmith and artisans	...	...	75	...	...	100
Total	....	....	$900	....	....	$1,450
III. Pay of workmen:						
3 runners	$735	$375	$1,110	$945	$375	$1,320
3 engineers	525	375	900	787	375	1,162

Total	$3,297	$1,543	$4,840	$4,228	$1,675	$5,903
IV. Materials:						
Wood[11]	1,968	...	$1,968	$1,968	...	$1,968
Lubricating material for a 5-ft. dredge[12] ...	500	...	500	600	...	600
Spare parts and material used for repairs[13]..	...	1,500	1,500	1,500	1,500	2,000
Total	$2,468	$1,500	$3,968	$3,068	$1,500	$4,568
V. Salaries of management:						
Manager and expert per annum	...	...	750	...	...	750
Assistant manager	...	...	450	...	...	450
Storekeeper	...	...	300	...	...	375
Apprentice	...	...	150	...	...	225
Total	...	...	$1,650	...	...	$1,800
VI. Taxes:[14]						
Land tax.....	...	...	125	...	...	125
Business license.	...	...	155	...	...	155
Personal business licenses..	...	...	50	...	...	50
Boiler tax[15].....	...	...	30	...	...	50
Mining police tax	...	...	25	...	...	...
Support of Gold Miners' Council	...	...	50	...	...	650
Total	...	...	$435	...	...	$1,030
VII. General expenses:						
Insurance	...	...	300	...	...	300
Correspondence (stamps, etc.).	...	...	125	...	...	200
Delivery of mail	...	...	75	...	...	...
Traveling expenses	...	...	250	...	...	175
Office expense...	...	...	25	...	...	50
Repairs to roads[16]	...	...	50	...	...	75
Repairs to houses[17]	...	...	150	...	...	200
Heating and lighting dwellings	...	...	250	...	...	375
Medical aid.....	...	...	300	...	...	500
Upkeep of two horses in the Urals and four in the Yenisei.	...	...	250	...	...	500
Driver	...	...	150	...	...	180
Watchman on the claims....	...	...	150	...	...	180
Accident insurance of workmen	...	...	200	...	...	300
Reception of visitors	...	...	50	...	...	75
Upkeep of agent in nearest large town	...	...	180	...	...	180
Total	....	....	$2,505	....	....	$3,290
VIII. Sundry small expenses	...	...	352	...	...	459
Grand total...	.....	.....	$15,000	.....	.....	$19,000

(1) The members of the Commission were: I. P. Beresnevich, A. A. Gerasimof, E. V. Grishin, A. P. Kyznetsof, C. I. Littauer, C. L. Perelman, N. P. Podsosof, I. I. Rogovin, D. M. Rebakof, and A. A. Savinik.

(2) The Commission takes the summer period from April 1/14 to November 1/14 because most of the dredges begin in the first half of April and finish in the second half of October—a period of seven months. The expenses for that period are exclusively operating expenses. These double dates refer to the two calendars.

(3) The Commission counts the winter period as the five months from November 1/14 to April 1/14, during which time the dredge is repaired and got ready for the following season. The expenses during this time are exclusively on account of repairs.

(4) For this estimate of the working expenses of a dredge the Commission has in view, besides the remarks under the several items of expense, the following general considerations: (*a*) At present most of the dredges employed in Russia are open-connected with buckets of 4½, 5, 6, and 7 cu. ft. capacity. The Commission determines the annual output of dredges working under normal conditions as:

	cu. yd.
4½-ft. dredge	165,100
5 " "	190,500
6 " "	228,600
7 " "	254,000

A 3-ft. dredge with close-connected buckets is equivalent as regards production, to a 5-ft., and a 5-ft. dredge is equivalent to 7-ft. dredge of the ordinary (open-connected) type. (*b*) In determining the different items of expense the Commission has had in view the probable maximum expense, and on this account the present estimate should be regarded as a limit which the expenses of a rightly organized dredging enterprise should not exceed; unless, in reality, there are local conditions altering some of the items. (*c*) The estimate is worked out for the two regions where the dredging industry is most largely developed at present, namely, the Ural and the Yenisei Taiga. For other auriferous districts the data of the estimate should be multiplied by a coefficient dependent on the greater or lesser cost of labor and transport in the said districts. (*d*) The Commission is unanimously of the opinion that working in three 8-hour shifts is the best system; and that all the organization of the dredge should be directed toward increased production. (*e*) The Commission considers it essential that the manager and the expert should be one person, since this combination gives great economic and technical advantages. (*f*) The foregoing estimate is based on a 5-ft. dredge with a production of 190,500 cu. yd. in a season; for other dredges the expenses for supplies should be altered, while the other items remain unchanged.

(5) This item refers only to the detailed prospecting needed for running the dredge, and assumes that the general prospecting for determining the value of the claims has already been carried out. The more thoroughly this latter prospecting has been done, the less the expense for the present item, and vice versa.

(6) In enumerating the expenses of the preparatory work all possible items are included, but it is to be remembered that only under rare and extraordinary conditions will all these items of expense exist at once. When working in river-beds the majority of the preparatory expenses are obviated.

(7) Side canals are found necessary with a short bucket-ladder in narrow workings and in the absence of rounded pontoon-corners. In new dredges this expense is absent.

(8) With a sufficient quantity of running water this expense is absent.

(9) This expense occurs when the dredge is working old claims, and depends on the amount of water, the slope of the valley, and the leakiness of the ground. Under unfavorable conditions it may reach $750 per annum.

(10) The number of wood-carriers depend on the amount of wood consumed, and must be increased for a large dredge.

(11) The amount of wood used for fuel can be estimated at 0.035 of the ground excavated, or for a 5-ft. dredge working 190,500 cu. yd. in a season, 1406 cords at $1.40 per cord. This amount includes the delivery to the dredge. In the Ural estimate is included the forest-tax, which does not exist in the Yenisei.

(12) The Commission does not give details for determining the amount of lubricating material; this includes crude oil, oleo-naphtha, cylinder-oil, tallow, belt-oil, grease, waste, hemp, packing, etc.

(13) The expense under this item is taken at $1500 to $2000 for a 4½ to 5-ft. dredge, and from $2000 to $3000 for a 6 to 7-ft. dredge. This expense includes all sorts of repair material, such as iron, steel, copper, zinc, coal, and wood.

(14) The taxes are based on the assumption that the dredging company owns 1350 acres, which area is large enough to guarantee the normal amortization, and the initial expense of fitting up the claim for one dredge.

(15) The boiler tax varies from $30 to $50, and depends on the size of the boiler.

(16) Here is understood the road to the claim.

(17) By this is understood repairs to dwellings and the sanitary upkeep of the claims.

The average normal expense for working one cubic yard, not including amortization, is as follows: (A) For ordinary (open-connected) dredges with the capacity given. (B) For close-connected dredges with buckets having the capacity given.

A.	In the Ural.	In the Yenisei.
4½ cu. ft.	9.00c.	11.50c.
5 " "	8.00	10.25
6 " "	7.00	9.25
7 " "	6.50	8.50

B.	In the Ural.	In the Yenisei.
3 cu. ft.	8.00	10.25
5 " "	6.50	8.50

Counting the average value of a zolotnik of gold at 4.80 rubles, or one dolya at 5 kopecks, we find that to cover the expenses of operating a dredge, not counting amortization for preparing the claims, the gravel must contain per cubic sagene: (C) For ordinary dredges with the capacity given. (D) For close-connected dredges with buckets of capacity given.

C.	In the Ural, doll.	In the Yenisei, doll.
4½ cu. ft.	44.80	57.00
5 " "	40.00	50.60
6 " "	35.50	45.50
7 " "	32.00	41.90

D.	In the Ural, doll.	In the Yenisei, doll.
3 cu. ft.	40.00	50.60
5 " "	32.00	41.90

The above-mentioned estimate of expenses was signed by the following members of the Commission: C. I. Littauer, A. P. Kyznetsof, A. A. Savinik, I. P. Beresnevich, N. P. Podsosof, and I. I. Rogovin.

In 4 (*a*) of the above report it is stated that a 5-ft. close-connected dredge ought to be equivalent to a 7-ft. dredge of the ordinary type. I think that this equivalency is wrong, for the capacity of a dredge depends upon two multipliers, the number of buckets and their size. In the opinion of the majority of the members of the Commission a 7-ft. dredge of the ordinary type should give 10 to 11 buckets per minute, or a maximum of 77 cu. ft. per minute. A 5½-ft. dredge (5-ft. dredges are no longer built in Russia) should give 18 buckets, or 99 cu. ft. per minute. Thus the relation between the two dredges

is 77:99, or 7:9, that is, a 5½-ft. close-connected dredge ought to be equal to a 9-ft. dredge of the ordinary type. (A. Gerasimof.*)

The following factors may be found useful in converting Russian statistics into English standards.

One pood = 36.113 pounds.
One pood pure gold = 21,157 rubles = $10,886.72.
One zolotnik = 0.137 Troy ounces = 2.835 of pure gold = 5.50964 rubles.
One dolya = 0.0014286 Troy ounces = $0.029532 of pure gold.
One 2000-lb. ton = 55.382 poods.
One pood = 0.0180564 tons.
One ruble = $0.514567 = 25.375 pence.
One ruble per cubic sagene = $0.04053 per cubic yard.
One ruble per pood = $28.50 per ton, $0.01425 per pound, $0.000977 per Troy ounce.
One zolotnik per cubic sagene pure gold = $0.223 per cubic yard.
One zolotnik per cubic sagene = approximately for placer gold $0.20 per cubic yard.
One dolya per cubic sagene pure gold = $0.0023245 per cubic yard.
One dolya per cubic sagene of placer gold = approximately $0.002 per cubic yard.
One zolotnik per 100 poods pure gold = $1.57 per ton, 2000 pounds.
One dolya per 100 poods = $0.0164 per 2000-lb. ton.
One zolotnik per 100 poods of placer gold = approximately $2 per cubic yard.
One dolya per 100 poods of placer gold = approximately $0.02 per cubic yard.
One cubic yard of gravel is reckoned as 3000 pounds.

COEUR D'ALENE LITIGATION SETTLED

The dispute over conflicting title to certain orebodies has been settled by agreement between the Bunker Hill & Sullivan M. & C. Co. and the Federal M. & S. Co., on terms arranged by the presidents of the two companies, with the advice and approval of their respective counsel, managers, and engineers. The terms of the settlement are given below:

1. The Federal company is to dismiss all litigation by it and by the January company, and the three companies are to interchange mutual releases of all demands.

2. The Federal company is to convey to the Bunker Hill company all of the Wardner properties owned or controlled by it and all interests which it has in such properties lying between Government gulch and Elk creek, and is to assign to the Bunker Hill company any and all stock owned or controlled by it in companies whose mines are situated between these boundaries. This includes the Federal company's mining claims, real estate, water rights, millsites (except sufficient ground to accommodate a new mill, the selection of which, if made at all, must be done before the contemplated conveyance is completed), mill, power, and mining plants, and all the appurtenances and equipment other than office appliances and any unused mining supplies. It embraces generally all the assets of the Federal company, commonly designated as its Wardner properties. The title to be conveyed to be free and clear of all encumbrances.

3. The Federal company reserves the right to mine in a workmanlike manner and work out expeditiously that portion of its properties which is free from any conflict with the Bunker Hill company described as follows: (1) All of the ground embraced within planes drawn vertically downward through the surface boundary lines of the Emma and Last Chance mining claims, together with the ground between planes drawn vertically downward through the northerly and southerly side-end lines of the Last Chance claim extended westerly in their own direction to their intersection with the northerly side-end line of the Bunker Hill mining claim extended westerly in its own direction. (2) All of the ground bounded by vertical planes drawn downward through the west end-line of the Tyler mining claim extended southerly in its own direction, the east end-line of the Viola mining claim extended southwesterly in its own direction and the northerly end-line of the Stemwinder mining claim as originally located extended westerly in its own direction. (3) All ground within planes drawn vertically downward through the surface boundary lines of the Omaha mining claim. Together with the right for this purpose, to use the mill mining plant and other necessary adjuncts and accessories. Said right to mine to continue until the ground is no longer susceptible of profitable working, the ground to be deemed worked out and exhausted whenever the Federal company shall have continued mining for a period of four consecutive months without making a profit.

4. In consideration of the foregoing to be done by the Federal company, the Bunker Hill company shall cause its capital stock to be increased to 327,000 shares of the par value of $10, and shall issue to the Federal company the 27,000 shares of increased capital.

RAILWAYS AND COAL IN ALASKA

The development of Alaska by railway construction and by the opening of the coalfields is of great importance both to Alaskans and to residents of the Western States. The Geological Survey issues every year several reports on Alaska, among them a volume containing a summary of the conditions of mining in Alaska and articles on subjects or regions of special interest. One of these volumes, Bulletin 284, issued in 1906, contains a discussion of possible railway routes in Alaska, together with a map showing the distribution of the mineral deposits and the practicable railway routes by which they may be reached.

The same volume contains a report discussing the possible markets for Alaskan coal and stating that the high grade of the coal and its coking qualities make it a valuable asset in the industrial advancement of the Pacific coast. The composition of Alaskan coals is given, and the possibility that they may have to compete with California petroleum is considered.

The bulletin contains also brief reports on the Bering River, Matanuska, and Herendeen Bay coalfields. The edition of the corresponding bulletins for 1906 and 1907 (Bull. 314 and 345) are exhausted, and only a few copies of the report for 1908 (Bull. 379) are available for distribution. Bulletin 345 contains the most complete economic map of Alaska yet published, showing the location of the gold placers, the gold and silver lode mines and prospects, the copper mines and prospects, the tin deposits, the coal-bearing rocks, and the areas that contain workable coal beds.

*Mr. Gerasimof is the dredge expert of the Putiloff Works.

Pine Canyon Smelter

STAFF CORRESPONDENCE

The plant of the International Smelting & Refining Co., in Utah, has a site on the mesa at the mouth of Pine canyon which drains from the Oquirrh range. The site overlooks Tooele valley and the southern end of Salt Lake. It is 700 ft. higher than Tooele station of San Pedro, Los Angeles & Salt Lake railroad, and about 1000 ft. above the surface-level of the lake. The company has built and put in operation the Tooele Valley railroad from Tooele station to the smelter-site, a distance of about five miles. The plant is on the opposite side of the main range from the Highland Boy mine of the Utah Consolidated Copper Co., and the mine and smelting plant are connected by an aerial tramway, erected by the Trenton Iron Works. The mine terminal is at an altitude of about 7000 ft., the summit over which the line crosses is at 9000 ft., and the smelter terminal is at about 5000 ft. The smelting plant is so far advanced that it will probably be ready to operate some time in July. The brick stack is an imposing structure, 25 ft. diam., and 350 ft. high, in the construction of which the ordinary grade of brick was used. The main flue, extending from the stack to the reverberatory furnaces, is 18 by 20 ft., and 1300 ft. long. The steel roaster building is built in two sections, with 16 McDougall roasters in each section, each roaster being 16 ft. diam. The fume, which will come from the roasters, is to be drawn into dust-chambers, hopper bottomed; the roof being held by outside iron girders. The structure enclosing these chambers is 140 by 120 ft. The fume passes from the dust-chambers through a 16 by 17-ft. flue into the main stack. The calcined ore in the roasters will be taken by electric haulage to the five reverberatory furnaces, Anaconda type, each 102 by 19 ft. The copper matte to be produced in the reverberatories will be drawn by gravity to the converters through iron launders lined with clay. Five stands of converters, made by Power & Mining Machinery Co., have been installed in a steel building erected for this purpose. The tilting of the converters is to be effected by electric motors. The converter building has one 60-ton electric crane for handling the blister copper and converter slag; also two transfer cranes, traveling at right-angles to the track of the main crane, and set 60 ft. high. The two cross-traveling cranes receive the slag-pots from the main crane and carry them to points over the reverberatories into which the slag is emptied through spouts. This is considered a unique feature, and one by which the transfer of the converter slag is expedited. H. N. Thomson, who is to be superintendent of the plant, states that by the calcining process in the roasters the sulphur in the ore probably will be reduced to 6½%. The five reverberatories will have the capacity of 1500 tons of charge in 24 hours. The ore that comes from the Highland Boy mine will be dumped from the tramway buckets into bins, and taken thence by electric cars to the receiving bins, and from the latter by belt-conveyor to the crushing and sampling mill, by which it is sampled and crushed to ½-in. size before being fed into the roasters. The mill is of steel and concrete. The power-plant, housed in a brick structure, contains two 750-kw. electric generators, Westinghouse make, one direct current and the other alternating. These are to be steam driven, four Sterling boilers supplying the steam, deriving the necessary heat from the reverberatory furnaces, utilizing what would otherwise be waste heat. These generators are to supply power for motors all over the premises and for electric haulage and lights. In the powerhouse are also two blowing engines to supply the blast for the converters. The electric power now used is transmitted to this place from the plant of the Telluride Power Co. The blacksmith shop and boiler shop occupy one steel building; in the main building are the machine shop, carpenter shop, storeroom, laboratory, and general offices. Construction work began a year ago, those in direct charge of designing and construction being C. H. Repath, chief engineer, and J. B. McIntosh, construction engineer; all under general authority of E. P. Mathewson.

Pine Canyon Plant of the International Smelting & Refining Company.

Limitations of One and Five Stamp Batteries

Written for the MINING AND SCIENTIFIC PRESS
By ALGERNON DEL MAR

The choice of machinery for any particular gold ore depends upon the chemical and physical characters of the precious metal and its enclosing rock. The chemical problems rest upon the facility with which gold forms an amalgam with mercury, and failing this its affinity for some solvent such as cyanide of potassium. The physical or mechanical problem may be due to moisture in the ore, or to its hardness. Amalgamators may be divided into two schools, those who claim that inside amalgamation is a faree, and those who claim that in most cases it is necessary if the object be to obtain a maximum extraction on the plates. The former hold that crushing with rolls or single unit stamps is sufficient because all that is required is for the crushed ore to pass over the plates. The latter desire units of five stamps and inside amalgamation with or without inside plates. They claim that the mercury should have a longer time to mix with the gold particles than that possible when the only contact is on the outside plates. On this difference of opinion and its practical results has hung the fate of many mining enterprises.

It is a notable fact that amalgamating inside single-unit batteries has in most cases been abandoned and the cyanide annex has come to be depended upon for a profitable extraction. There are exceptions, no doubt, as there are exceptional deposits of ore. It is impossible, however, to amalgamate inside single-unit batteries and they must be considered only as crushing machines. The screen surface being so great, and the area between the dies and screen opening (other than that occupied by the stamp) being so limited, any particle that will pass the screen is at once thrown out. This means that any mercury fed inside is thrown out before it has had time to mix with the ore. Making an inside clean-up of a single-unit battery is seldom worth the time wasted. It is not important to take out the dies at a monthly clean-up unless they need to be turned or replaced. With a 5-stamp unit this is not so even if the width at discharge is only 12 inches. The mercury has time to mix with the ore and forms more or less amalgam before being thrown through the screen.

In an amalgamating test the sample of ore is ground with mercury, or the ground ore is thoroughly mixed with mercury, the pulp is diluted with water, and the amalgam collected. This represents, in one sense, the amount recoverable by amalgamation, but it does not represent the amount recoverable by amalgamating with a single-unit mill. Why not duplicate the action that takes place in practice? Make two tests, the first as above outlined, running the pulp over ten feet of amalgamated plates, and the other by passing ground pulp, that has not been mixed with mercury, over the same length of plate. If the results are the same there is no question of the preference. There are many ores that plate easily outside the mortar and there are many that do not. To expect fine gold or coarse gold that may be coated with some objectionable material, to amalgamate by simply running over a sensitive plate is to expect too much. This gold must be well mixed with mercury first, as is done inside a 5-stamp unit. The usefulness of this system, however, has its limits because single-unit batteries crush ore at less expense and the cyanide process may permit recovery of the gold that escaped amalgamating. The preference is a question of profits, which means definite preliminary experiments before committing the mine to its final trial. Because a machine can crush ore at less expense is little recommendation for its use unless the ultimate result is a gain.

To reason inductively, to arrive at some generalizations, certain figures must be assumed as representing results actually obtained by experiment on a given ore. The tests necessary are: (1) Fineness
